Mr. Cotes goes yet farther. Giving a view of Newton's philosophy, he asserts that gravity is to be ranked among the primary qualities of all bodies; and deemed equally essential to matter as extension, mobility, or impenetrability. Prefat. ad Newt. Princip. But Newton himself disclaims this notion; and to show that he does not take gravity to be essential to bodies, he declares his opinion of the cause; choosing to propose it by way of query, not being yet sufficiently satisfied about its experiments. Thus, after having shown that there is a medium in nature vastly more subtle than air, by whose vibrations sound is propagated, by which light communicates heat to bodies, and by the different densities of which the refraction and reflection of light are performed; he proceeds to inquire: "Is not this medium much rarer within the dense bodies of the sun, stars, planets, and comets, than in the empty celestial spaces between them? And in passing from them to greater distances, doth it not grow denser and denser perpetually, and thereby cause the gravity of those great bodies towards one another, and of their parts towards the bodies; every body endeavouring to recede from the denser parts of the medium towards the rarer?

"For if this medium be supposed rarer within the Sun's body than at its surface, and rarer there than at the hundredth part of an inch from his body, and rarer there than at the fiftieth part of an inch from his body, and rarer there than at the orb of Saturn; I see no reason why the increase of density should stop any where, and not rather be continued through all distances from the Sun at Saturn, and beyond.

"And though this increase of density may at great distances be exceeding slow; yet if the elastic force at this medium be exceeding great, it may suffice to impel bodies from the denser parts of the medium towards the rarer with all that power which we call gravity.

"And that the elastic force of this medium is exceeding great, may be gathered from the swiftness of its vibrations. Sounds move about 1140 English feet in a second of time, and in seven or eight minutes of time they move about 100 English miles: light moves from the Sun to us in about seven or eight minutes of time; which distance is about 70,000,000 English miles, supposing the horizontal parallax of the Sun to be about twelve seconds; and the vibrations, or pulses of this medium, that they may cause the alternate fits of easy transmission, and easy reflection, must be swifter than light, and by consequence above 7000000 times swifter than sounds; and therefore the elastic force of this medium, in proportion to its density, must be above 7000000×7000000 (that is, above 49,000,000,000,000) times greater than the elastic force of the air is in proportion to its density: for the velocities of the pulses of elastic mediums are in a subduplicate ratio of the elasticities and the rarities of the mediums taken together.

"As magnetism is stronger in small load-stones than in great ones, in proportion to their bulk; and gravity is stronger on the surface of small planets than those of great ones, in proportion to their bulk; and small bodies are agitated much more by electric attraction than great ones: so the smallness of the rays of light may contribute very much to the power of the agent by which they are refracted; and if any one should suppose that æther (like our air) may contain particles which endeavour to recede from one another (for I do not know what this æther is), and that its particles are exceedingly smaller than those of air, or even than those of light; the exceeding smallness of such particles may contribute to the greatness of the force by which they recede from one another, and thereby make that medium exceedingly more rare and elastic than air, and of consequence exceedingly less able to resist the motions of projectiles, and exceedingly more able to press upon gross bodies by endeavouring to expand itself." Optics, p. 325, &c.

Gravity, in mechanics, denotes the tendency of bodies towards the centre of the earth. That part of mechanics which considers the equilibrium, or motion of bodies arising from gravity or weight, is particularly called statics.

Gravity in this view is distinguished into absolute and relative.

Absolute Gravity is that with which a body descends freely and perpendicularly through an unresisting medium. See Mechanics.

Relative Gravity is that with which a body descends on an inclined plane, or through a resisting medium, or as opposed by some other resistance. See Mechanics.

Gravity, in hydrostatics. The laws of bodies gravitating in fluids make the business of hydrostatics.

Gravity is here divided into absolute and specific.

Absolute, or *true* Gravity, is the whole force with which the body tends downwards.

Specific Gravity, is the relative, comparative, or apparent gravity in any body, in respect of that of an equal bulk or magnitude of another body; denoting that gravity or weight which is peculiar to each species or kind of body, and by which it is distinguished from all other kinds.

In this sense a body is said to be specifically heavier than another, when under the same bulk it contains a greater weight than that other; and reciprocally the latter is said to be specifically lighter than the former. Thus, if there are two equal spheres, each one foot in diameter; the one of lead, and the other of wood: since the leaden one is found heavier than the wooden one, it is said to be specifically, or in specie, heavier; and the wooden one specifically lighter.

This kind of gravity is by some called relative; in opposition to absolute gravity, which increases in proportion to the quantity or mass of the body.

Laws of the specific gravity of bodies.

I. If two bodies are equal in bulk, their specific gravities are to each other as their weights, or as their densities.

II. If two bodies are of the same specific gravity or density, their absolute weights will be as their magnitudes or bulks.

III. In bodies of the same weight, the specific gravities are reciprocally as their bulks.

IV. The specific gravities of all bodies are in a ratio compounded of the direct ratio of their weights and re-

ciprocal ratio of their magnitudes. And hence again the specific gravities are as the densities.

V. The absolute gravities or weights of bodies are in the compound ratio of their specific gravities and magnitudes or bulks.

VI. The magnitudes of bodies are directly as their weights, and reciprocally as their specific gravities.

VII. A body specifically heavier than a fluid, loses as much of its weight when immersed in it, as is equal to the weight of a quantity of the fluid of the same bulk or magnitude.

Hence, since the specific gravities are as the absolute gravities under the same bulk; the specific gravity of the fluid, will be to that of the body immerged, as the part of the weight lost by the solid, is to the whole weight.

And hence the specific gravities of fluids are as the weights lost by the same solid immerged in them.

VIII. *To find the specific gravity of a fluid or of a solid.* On one arm of a balance suspend a globe of lead by a fine thread, and to the other fasten an equal weight, which may just balance it in the open air. Immerge the globe into the fluid, and observe what weight balances it then, and consequently what weight is lost, which is proportional to the specific gravity as above. And thus the proportion of the specific gravity of one fluid to another is determined by immersing the globe successively in all the fluids, and observing the weights lost it each, which will be the proportions of the specific gravities of the fluids sought.

This same operation determines also the specific gravity of the solid immerged, whether it is a globe, or of any other shape or bulk, supposing that of the fluid known. For the specific gravity of the fluid is to that of the solid, as the weight lost is to the whole weight.

Hence also may be found the specific gravity of a body that is lighter than the fluid, as follows:

IX. *To find the specific gravity of a solid that is lighter than the fluid, as water, in which it is put.* Annex to the lighter body another that is much heavier than the fluid, so that the compound mass may sink in the fluid. Weigh the heavier body and the compound mass separately, both in water and out of it; then find how much each loses in water, by subtracting its weight in water from its weight in air; and subtract the less of these remainders from the greater.

Then, As this last remainder,
Is to the weight of the light body in air,
So is the specific gravity of the fluid,
To the specific gravity of that body.

X. The specific gravities of bodies of equal weight, are reciprocally proportional to the quantities of weight lost in the same fluid. And hence is found the ratio of the specific gravities of solids, by weighing in the same fluids, masses of them that weigh equally in air, and noting the weights lost by each.

The specific gravities of many kinds of bodies, both solid and fluid, have been determined by various authors. It will be sufficient here to give those of some of the most usual bodies that have been determined with the greater certainty. The numbers in this table express the number of avoirdupoise ounces in a cubic foot of each body, that of common water being just 1000 ounces, or $62\frac{1}{2}$lb.

A TABLE

OF THE SPECIFIC GRAVITIES OF DIFFERENT BODIES, ARRANGED ALPHABETICALLY.

Metals.

Antimony, crude	4064
glass of	4946
molten	6702
Arsenic, glass of, natural	3594
molten	5763
native orpiment	5452
Bismuth, molten	9823
native	9020
ore of, in plumes	4371
Brass, cast, not hammered	8396
ditto, wiredrawn	8544
cast, common	7824
Cobalt, molten	7812
blue glass of	2441
Copper, not hammered	7788
the same wiredrawn	8878
ore of soft copper, or natural verdigr.	3572
Gold, pure, of 24 caracts, melted, but not hammered	19258
the same hammered	19362
Parisian standard, 22 car. not hammered	17486
the same hammered	17589
guinea of Geo. II.	17150
guinea of Geo. III.	17629
Spanish gold coin	17655
Holland ducats	19352
trinket standard, 20 car. not hammered	15709
the same hammered	15775
Iron, cast	7207
bar, either hardened or not	7788
Steel, neither tempered nor hardened	7833
hardened, but not tempered	7840
tempered and hardened	7818
ditto not hardened	7816
Iron, ore prismatic	7355
ditto specular	5218
ditto lenticular	5012
Lead, molten	11352
ore of, cubic	7587
ditto horned	6072
ore of black lead	6745
ditto white lead	4059
ditto ditto vitreous	6558
ditto red lead	6027
ditto saturnite	5925
Manganese, striated	4756
Molybdena	4738
Mercury, solid, or congealed	15632
fluent	13568
natural calx of	9230
precipitate per se	10871
precipitate, red	8399
brown cinnabar	10218
red cinnabar	6902
Nickel, molten	7807
ore of, called kupfernickel of Saxe	6648
kupfernickel of Bohemia	6607
Platina, crude, in grains	15602
purified, not hammered	19500
purified, hammered	20337

Platina, ditto wiredrawn	21042
ditto rolled	22069
Silver, virgin, 12 deniers, fine, not ham.	10744
ditto hammered	10511
Paris standard	10175
shilling of Geo. II.	10000
shilling of Geo. III.	10534
French coin	10408
Tin, pure Cornish, melted, not hardened	7291
the same hardened	7299
of Malacca, not hardened	7296
the same hardened	7307
ore of, red	6935
ore of, black	6901
ore of, white	6008
Tungsten	6066
Uranium	6440
Wolfram	7119
Zinc, molten	7191
Precious stones.	
Beryl, or aqua-marine, oriental	3549
ditto occidental	2723
Chrysolite, of the jewellers	2782
of Brazil	2692
Chrystal, pure rock of Madagascar	2653
of Brazil	2653
European	2655
rose-coloured	2670
yellow	2654
violet, or amethyst	2654
white amethyst	2651
Carthaginian	2657
black	2654
Diamond, white oriental	3521
rose-coloured oriental	3531
orange ditto	3550
green ditto	3524
blue ditto	3525
Brazillian	3444
yellow	3519
Emerald of Peru	2775
Garnet of Bohemia	4189
of Syria	4000
dodecaedral	4063
volcanic, 24 faces	2468
Girasol	4000
Hyacinth, common	3687
Jargon of Ceylon	4416
Quartz, crystallised	2655
in the mass	2647
brown crystallised	2647
fragile	2640
milky	2652
fat, or greasy	2646
Ruby, oriental	4283
spinell	3760
ballas	3646
Brazilian	3531
Sapphire, oriental	3994
ditto white	3991
of Puys	4077
Brazilian	3131
Spar, white sparkling	2595
Spar, red ditto	2438
green ditto	2704
blue sparkling	2693
green and white ditto	3105
transparent ditto	2564
adamantine	3873
Topaz, oriental	4011
pistachio ditto	4061
Brazilian	3536
of Saxe	3564
white ditto	3554
vermilion	4230
Silicious stones.	
Agate, oriental	2590
onyx	2638
cloudy	2625
speckled	2607
veined	2667
stained	2632
Calcedony, common	2616
transparent	2664
veined	2606
reddish	2665
blueish	2587
onyx	2615
Cornelian, pale	2630
speckled	2612
veined	2623
onyx	2623
stalactite	2598
simple	2613
Flint, white	2594
black	2582
veined	2612
Egyptian	2565
Jade, white	2950

Weight and specific gravities of different gases.

Fahrenheit's therm. 55°	Spec. grav.	Barom. 30 inch. Wt. cub. foot.
Atmospheric air	1.2	525.0 grs.
Hydrogenous gas	0.1	43.75
Oxygenous gas	1.435	627.812
Azotic gas	1.182	517.125
Nitrous gas	1.4544	636.333
Ammoniac. gas	.7311	319.832
Sulphur. acid gas	2.7611	1207.978

In this table the weights and specific gravities of the principal gases are given, as they correspond to a state of the barometer and thermometer which may be chosen for a medium. The specific gravity of any one gas to that of another will not conform to exactly the same ratio under different degrees of heat and other pressures of the atmosphere, because the various expansions by no means follow the same law.

These numbers being the weight of a cubic foot, or 1728 cubic inches, of each of the bodies, in avoirdupois ounces, by proportion the quantity in any other weight, or the weight of any other quantity, may be readily known.

For example. Required the content of an irregular block of millstone which weighs 1 cwt. or 112 lb. or 1792 ounces. Here, as 2500 : 1792 : :1728 : 1228$\frac{4}{5}$ cubic inches the content.

Ex. 2. To find the weight of a block of granite, whose length is 63 feet, and breadth and thickness each 12 feet; being the dimensions of one of the stones of granite in the walls of Balbec. Here $63 \times 12 \times 12 = 9072$ feet is the content of the stone; therefore as 1 : 9072 : : 3500 oz. 31752000 oz. or 885 tons 18 cwt. 3 qrs. the weight of the stone.

XI. A body descends in a fluid specifically lighter, or ascends in a fluid specifically heavier, with a force equal to the difference between its weight and that of an equal bulk of the fluid.

XII. A body sinks in a fluid specifically heavier, so far as that the weight of the body is equal to the weight of a quantity of the fluid of the same bulk as the part immersed. Hence, as the specific gravity of the fluid, is to that of the body, so is the whole magnitude of the body, to the magnitude of the part immersed.

XIII. The specific gravities of equal solids are as their parts immerged in the same fluid.

The several theorems here delivered are both demonstrable from the principles of mechanics, and are also equally comformable to experiment, which answers exactly to the calculation. See Hydrostatics.

Gravity, in music. Gravity is that modification of any sound by which it becomes deep or low in respect of some other sound: the gravity of sounds depends on the thickness and distension of the chords, or the length and diameter of the pipes, and in general on the mass, extent, and tension, of the sonorous bodies. The larger and more lax are the bodies, the slower will be the vibrations, and the graver the sounds.

GRAUSTEIN, in mineralogy, is a rock composed of small grains of felspar and hornblende, which graduate into each other, and form a mass almost homogenous of an ash-grey colour. It contains olivine and augite.

GREAT-circle sailing, the manner of conducting a ship in, or rather pretty near, the arch of a great circle, that passes through the zenith of the two place, viz. whence she came, and to which she is bound.

GREEN-CLOTH, a board, or court of justice, held in the compting-house of the king's household, composed of the lord-steward, and officers under him, who sit daily. To this court are committed the charge and oversight of the king's household in matters of justice and government, with a power to correct all offenders, and to maintain the peace of the verge, or jurisdiciton of the court.

royal; which is every way about two hundred yards from the last gate of the palace where his majesty resides. It takes its name from a green cloth spread over the board where they sit. Without a warrant first obtained from this court, none of the king's servants can be arrested for debt.

Green-finch, in ornithology. See Fringilla.

Green-house, or conservatory, a house in a garden contrived for sheltering and preserving the most tender and curious exotic plants, which, in our climate, will not bear to be exposed to the open air during the winter season. These are generally large and beautiful structures, equally ornamental and useful.

GREENLAND Company. A joint stock of 40,000*l.* was by statute to be raised by subscribers, who were incorporated for 14 years from the 1st of October, 1693, and the company to use the trade of catching whales, &c. into and from Greenland and the Greenland seas. They make bye-laws for the government of the persons employed in their ships, &c. Stat. 4 and 5 W. III. cap. 17. This company was farther encouraged by parliament in 1696; but partly by unskilful management, and partly by real losses, it was under the necessity of entirely breaking up, before the expiration of the term assigned to it, ending in 1707. But any person who will adventure to Greenland for whale-fishing shall have all the privileges granted to the Greenland company by 1 Anne, cap. 16, and thus the trade was again laid open. Any subjects may import whale-fins, oil, &c. of fish caught in the Greenland seas, without paying any customs, &c. Stat. 10 Geo. I. cap. 16. And ships employed in the Greenland fishery are to be of a given burden, provided with boats, so many men, fishing-lines, harping-irons, &c. and be licensed to proceed; and on their return shall be paid 20*s.* per ton bounty for whale-fins, &c. imported. 6 Geo. II. cap. 33. The bounty was afterwards increased, but has been lately diminished; and since this diminution the trade has increased. See Balæna, and Fishery.

GREGORIAN Calendar. See Calendar, and Epact.

Gregorian Epoch, the epocha or time whence the Gregorian calendar or computation took place.

Gregorian Year, the Julian year corrected or modelled, in such a manner as that three secular years, which in the Julian account are bissextile, are here common years, and only every fourth seculiar year is made a bissextile year.

The Julian computation is more than the solar year by eleven minutes, which in 131 years amounts to a whole day. By this calculation the vernal equinox was anticipated 10 days from the time of the general council of Nice, held in the year 325 of the christian æra, to the time of pope Gregory XIII. who therefore caused 10 days to be taken out of the month of October, in 1582, to make the equinox fall on the 21st of March, as it did at the time of that council; and to prevent the like variation for the future, he ordered that three days should be abated in every 400 years, by reducing the leap year at the close of each century for three successive centuries to common years, and retaining the leap-year at the close of each fourth century only. This was at that time esteemed as exactly conformable to the true solar year, but it is found not to be strictly just, because that in 400 years it gets one hour and twenty minutes; and consequently in 7200 years, a whole day.

The greatest part of Europe have long used the Gregorian style; but Great Britain retained the Julian till the year 1752, when by act of parliament this style was adjusted to the Gregorian; since which time Sweden, Denmark. and other European states, who computed time by the Julian account, have followed this example.

GREWIA, a genus of the polyandria order, in the gynandria class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is pentaphyllous; there are five petals, each with a nectariferous scale at the base; the berry is quadrilocular. The species are 13. The most remarkable are:

1. The occidentalis, with oval crenated leaves, has long been preserved in many curious gardens both in England and Holland. It is a native of the Cape of Good Hope, and grows to the height of 10 or 12 feet. The stem and branches greatly resemble those of the small-leafed elm, the bark being smooth, and of the same colour with that when young. The leaves are also very like those of the elm, and fall off in autumn. The flowers are produced singly along the young branches from the wings of the leaves, and are of a bright purple colour.

2. The africana, with oval spear-shaped serrated leaves, is a native of Senegal in Africa, whence its seeds were brought by Mr. Adanson. In England it rises with a shrubby stalk five or six feet high, sending out many lateral branches, with a brown hairy bark, and garnished with spearshaped serrated leaves; but the plants have not flowered in Britain.

The first sort, though a native of a warm climate, will bear the open air in this country; only requiring to be sheltered in a green-house during the winter time. It may be propagated by cuttings or layers planted in pots filled with soft loamy earth. The second sort is tender, and must be kept constantly in a warm bark-stove. In summer they require a large share of the free air to be admitted to them, and should have water three or four times a week in warm weather; but in the winter they must be sparingly watered. The negroes of Senegal consider a decoction of the bark of this last species as a never-failing remedy against venereal complaints.

GREWT, among miners, signifies earth of a different colour from the rest, found on the banks of rivers as they are searching for mines.

GREYHOUND. See Canis.

GRIAS, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is tetrapetalous; the calyx quadrifid; the stigma sessile and cruciform: the fruit is a plum with an eight-furrowed kernel. There is but one species, the cauliflora, or anchovy pear, a native of Jamaica. The leaves are nearly oval. and about three feet long. It has a straight stem, upon the upper part of which come forth the flowers. The fruit is large, and contains a stone with eight furrows. These fruits are eaten by the inhabitants.

GRIELUM, a genus of the pentagynia order, in the decandria class of plants. The calyx is quinquefid; there are five petals; the filaments persisting; and there are five

monospermous seed-cases. There is one species, a herb of the Cape.

GRIFFON, in heraldry, an imaginary animal, feigned by the ancients to be half eagle and half lion; by this form they intended to give an idea of strength and swiftness joined together, with an extraordinary vigilance in guarding the things entrusted to its care.

GRINDING, *trituratio*, the reducing hard substances to fine powders, either by the mortar, or by way of levigation, upon a marble. See MILLWORK.

GRIPE, in the sea language, is a piece of timber stayed against the lower piece of the stern, from the foremast end of the keel, joining with the knee of the head: its use is to defend the lower part of the stern from any injury; but it is often made the larger, to make the ship keep a good wind.

GRISLEA, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. The calyx is quadrifid; and there are four petals, one from each incisure of it. The filaments are very long, ascending or turning upwards; the capsule is globose, superior, unilocular, and polyspermous. There are two species; one a tree of South America, the other a shrub of the East Indies.

GRIST, in country-affairs, denotes corn ground, or ready for grinding. See FLOUR-MILL.

GRIT, a genus of argillaceous earths. Its texture is more or less porous, equable, and rough to the touch. It does not give fire with steel, nor effervesce with acids. When fresh broken and breathed upon, it exhales an earthy smell. Mr. Kirwan mentions two kinds; one from Hollington, near Uttoxeter, of a yellowish or whitish grey, and about the specific gravity of 2288. Another, from Kneperslev in Staffordshire, is of the specific gravity of 8568, and so infusible as to be used for fire-stones. According to Fabroni the grit-stone is of greater or less hardness, mostly of a grey, and sometimes of a yellowish colour, composed of a siliceous and micaceous sand, but rarely of a sparry kind; with greater or smaller particles closely compacted by an argillaceous cement. It gives some sparks with steel, is indissoluble for the most part in acids, and vitrifiable in a strong fire. It is used for millstones and whetstones, and sometimes for filtering-stones and for building.

GROGRAM, a kind of stuff, made of silk and mohair.

GRONOVIA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 34th order, cucurbitacæ. There are five petals and stamina inserted into a campanulated calyx; the berry is dry, monospermous, and inferior. There is one species, an annual of La Vera Cruz.

GROOM, a name particularly applied to several superior officers belonging to the king's household, as groom of the chamber, groom of the stole.

GROOVE, among miners, is the shaft or pit sunk into the earth, sometimes in the vein, and sometimes not.

GROOVE, among joiners, the channel made by their plough in the edge of a moulding style, or rail, to put their pannels in. in wain-scotting.

GROSS, in law-books, signifies absolute or independent on another: thus, an advowson in gross, is one distinct and separate from the manor.

GROSS also denotes the quantity of twelve dozen, of things sold by tale.

GROSS-BEAK, in ornithology. See LOXIA.

GROSS-WEIGHT, the whole weight of merchandizes, with their dust and dross; as also the bag or chest wherein they are contained. An allowance is usually made out of the gross weight for tare and tret. See TARE.

GROTESQUE, in sculpture and painting, something whimsical, extravagant, and monstrous; consisting either of things that are merely imaginary, and have no existence in nature, or of things so distorted, as to raise surprize and ridicule. Grotesque work is the same with what is sometimes called antique. The name is said to have taken its rise from the figures of this kind much used in adorning the grottos which in ancient times were the tombs of eminent persons or families; such as that of Ovid, whose grotto was discovered near Rome about 100 years ago.

GROTTO, or GROTTA, a large deep cavern or den in a mountain or rock. The word is Italian, grotta; formed, according to Menage, &c. from the Latin crypta. Du Cange observes, that grotta was used in the same sense in the corrupt Latin. The ancient anchorites retired into dens and grottos, to apply themselves the more attentively to meditation. Okey-hole, Elden-hound, Peak's-hole, and Pool's-hole, are famous among the natural caverns or grottos of our country. The entrance to Okey-hole, on the south side of Mendip-hills, is in the fall of those hills, which is beset all about with rocks, and has near it a precipitate descent of near twelve fathoms deep, at the bottom of which there continually issues from the rocks a considerable current of water. The naked rocks above the entrance show themselves about 30 fathoms high, and the whole ascent of the hill above is about a mile, and is very steep. As you pass into this vault, you go at first upon a level; but advancing farther, the way is found to be rocky and uneven, sometimes ascending, and sometimes descending. The roof of this cavern, in the highest part, is about eight fathoms from the ground, but in many particular places it is so low that a man must stoop to get along. The breadth is not less various than the height, for in some places it is five or six fathoms wide, and in others not more than one or two. It extends itself in length about two hundred yards. People talk much of certain stones in it, resembling men and women, and other things; but there is little matter of curiosity in these, being only shapeless lumps of common spar. At the farthest part of the cavern there is a good stream of water large enough to drive a mill, which passes all along one side of the cavern, and at length slides down about six or eight fathoms among the rocks, and then passing through the clefts of them, discharges itself into the valley. The river within the cavern is well stored with eels, and has some trouts in it; and these cannot have come from without, there being so great a fall near the entrance. In dry summers a great number of frogs are seen all along this cavern, even to the farthest part of it; and on the roof of it, at certain places, hang vast numbers of bats, as they do in almost all caverns, the entrance of which is either level, or but slightly ascending or decending; and even in the more perpendicular ones they are sometimes found, provided they are not too narrow, and are sufficiently high. The cattle that feed in the pastures through which this river runs have been

known to die suddenly sometimes after a flood; this is probably owing to the waters having been impregnated, either naturally or accidentally, with lead ore.

Elden-hole is a huge profound perpendicular chasm, three miles from Buxton, ranked among the natural wonders of the Peak. Its depth is unknown, and is pretended to be unfathomable. Cotton tells us he sounded 884 yards, yet the plummet still drew. But he might easily be deceived, unless his plummet was very heavy; the weight of a rope of that length might well make the landing of the plummet scarcely perceivable.

Peak's-hole, and Pool's-hole, are two remarkable horizontal cavities under mountains; the one near Castleton, the other just by Buxton. They seem to have owed their origin to the springs which have their current through them; when the water had forced its way through the horizontal fissures of the strata, and had carried the loose earth away with it, the loose stones must fall down of course: and where the strata had few or no fissures, they remained entire; and so formed these very irregular arches, which are now so much wondered at. The water which passes through Pool's-hole is impregnated with particles of limestone, and has incrusted the whole cavern in such a manner that it appears as one solid rock.

In grottos are frequently found crystals of the rock, stalactites, and other natural conglaciations, and those often of an amazing beauty. M. Homberg conjectures, from several circumstances, that the marble pillars in the grotto of Antiparos vegetate or grow. That author looks on this grotto as a garden, in which the pieces of marble are the plants; and endeavours to show, that they could only be produced by some vegetable principle.

At Foligno in Italy is another grotto, consisting of pillars and orders of architecture of marble, with their ornaments, &c. scarcely inferior to those of art; but they all grow downwards: so that if this too is a garden, the plants are turned upside down.

Grotto *del Cani,* is a little cavern near Pozzuoli, four leagues from Naples, the steams whereof are of a mephitical or noxious quality; whence also it is called bocca venenosa, the poisonous mouth. "Two miles from Naples (says Dr. Mead), just by the Lago de Agnano, is a celebrated Moseta, commonly called la Grotta del Cani, and equally destructive to all within the reach of its vapours. It is a small grotto about eight feet high, twelve long, and six broad; from the ground arises a thin, subtile, warm fume, visible enough to a discerning eye, which does not spring up in little parcels here and there, but in one continued stream, covering the whole surface of the bottom of the cave; having this remarkable difference from common vapours, that it does not, like smoke, disperse itself into the air, but quickly after its rise falls back again, and returns to the earth; the colour of the sides of the grotto being the measure of its ascent: for so far it is of a darkish green, but higher only common earth. And as I myself found no inconvenience by standing in it, so no animal, if its head is above this mark, is the least injured. But when, as the manner is, a dog, or any other creature, is forcibly kept below it; or, by reason of its smallness, cannot hold its head above it, it presently loses all motion, falls down as dead, or in a swoon; the limbs convulsed and trembling, till at last no more signs of life appear than a very weak and almost insensible beating of the heart and arteries; which, if the animal is left a little longer, quickly ceases too, and then the case is irrevocable; but if it is snatched out and laid in the open air, it soon comes to life again, and sooner if thrown into the adjacent lake." The steam or moefite of the grotto del cani is now well known to be carbonic acid gas. See Chemistry.

Grotta del Serpi, is a subterraneous cavern near the village of Sassa, eight miles from the city of Braccano in Italy, described by Kircher thus: "The grotta del serpi is big enough to hold two persons. It is perforated with several fistular apertures, somewhat in the manner of a sieve; out of which, at the beginning of the spring season, issues a numerous brood of young snakes of divers colours, but all free from any particular poisonous quality. In this cave they expose their lepers, paralytics, arthritics, and elephantiac patients, quite naked; where, the warmth of the subterraneous steams resolving them into a sweat, and the serpents clinging variously all around, licking and sucking them, they become so thoroughly freed of all their vicious humours, that upon repeating the operation for some time, they become perfectly restored." This cave Kircher visited himself; and found it warm, and every way agreeable to the description given of it. He saw the holes, and heard a murmuring hissing noise in them. Though he missed seeing the serpents, it not being the season of their creeping out, yet he saw a great number of their exuviæ or sloughs, and an elm growing hard by laden with them. The discovery of the virtues of this cave was by the cure of a leper going from Rome to some baths near this place. Losing his way, and being benighted, he happened upon this cave. Finding it very warm, he pulled off his clothes; and being weary and sleepy, had the good fortune not to feel the serpents about him till they had wrought his cure.

Grotto, *Milky,* Crypta Lactea, a mile distant from the ancient village of Bethlehem, is said to have been thus denominated on occasion of the Blessed Virgin, who let fall some drops of milk in giving suck to Jesus in this grotto. And hence it has been commonly supposed, that the earth of this cavern has the virtue of restoring milk to women that are grown dry, and even of curing fevers. Accordingly, they are always digging in it, and the earth is sold at a good rate to such as have folly enough to give credit to the fable. An altar has been built on the place, and a church just by it.

Grotto is also used for a little artificial edifice made in a garden, in imitation of a natural grotto. The outsides of these grottos are usually adorned with rustic architecture, and their inside with shell-work, fossils, &c. finished likewise with jets-d'eau or fountains, &c. A cement for artificial grottos may be made thus: Take two parts of white rosin, melt it clear, and add to it four parts of bees'-wax; when melted together, add two or three parts of the powder of the stone you design to cement, or so much as will give the cement the colour of the stone. With this cement, the stone, shells, &c. after being well dried before the fire, may be cemented. Artificial red coral branches, for the embellishment of grottos, may be made in the following manner: Take clear rosin, dissolve it in a brass-pan, to every ounce of which add two drams of the finest vermilion; when you have stirred

them well together, and have chosen your twigs and branches, peeled and dried, take a pencil and paint the branches all over whilst the composition is warm; afterwards shape them in imitation of natural coral. This done, hold the branches over a gentle coal-fire, till all is smooth and even as if polished. In the same manner white coral may be prepared with white lead, and black coral with lamp-black. A grotto may be built with little expense, of glass, cinders, pebbles, pieces of large flint, shells, moss, stones, counterfeit coral, pieces of chalk, &c. all bound or cemented together with the above-described cement.

GROUND, in painting, the surface upon which the figures and other objects are represented. See PAINTING.

GROUND-TACKLE, a ship's anchors, cables, and in general whatever is found necessary to make her ride safe at anchor.

GROUND-IVY, in botany. See GLECHOMA.

GROUND-*Pine*. See TEUCRIUM.

GROUNDAGE, a custom or tribute paid for the ground on which a ship stands in port.

GROUNDSEL, in botany, &c. See SENECIO.

GROUP, in painting and sculpture, is an assemblage of two or more figures of men, beasts, fruits, &c. which have some apparent relation to each other, &c. See PAINTING.

GROUSE, or GROWSE. See TETRAO.

GROWAN, among the miners of Cornwall, a coarse gritty stone, of a greyish colour, which they are often obliged to dig through before they can reach the ore.

GRUNSTEIN, primitive, is a mixture of hornblende and felspar; and is divided into different varieties, according as its texture is granular or compact. See ROCKS PRIMITIVE.

GRY, a measure containing one-tenth of a line. A line is one-tenth of a digit, and a digit one-tenth of a foot, and a philosophical foot one-third of a pendulum whose diadromes, or vibrations, in the latitude of 45 degrees, are each equal to one second of time, or one-sixtieth of a minute.

GRYGALLUS, in ornithology, a name given to the urogallus, or tetrao. See TETRAO.

GRYLLUS, the *locust*, *grasshopper*, and *cricket*, in entomology, a genus of insects belonging to the order hemiptera. The generic character is, head inflected, armed with jaws, and furnished with feelers. Antennæ, in most species, either filiform or setaceous. Wings four, deflex, convoluted: lower wings pleated. Hind legs formed for leaping: claws double on all the feet. There are 61 species, of which the following are most worthy of notice:

1. Among the most numerous species is the gryllus migratorius of Linnæus, or common migratory locust, which of all the insects capable of injuring mankind seems to possess the most dreadful powers of destruction. Legions of these animals are from time to time observed in various parts of the world, where the havock they commit is almost incredible: whole provinces are in a manner desolated by them in the space of a few days, and the air is darkened by their numbers: nay even when dead they are still terrible; since the putrefaction arising from their inconceivable number is such that it has been regarded as one of the probable causes of pestilence in the Eastern regions. This formidable locust is generally of a brownish colour, varied with pale red, or flesh-colour, and the legs are frequently blueish. In the year 1748, it appeared in irregular flights in several parts of Europe, as in Germany, France, and England; and in the capital itself and its neighbourhood great numbers were seen: they perished, however, in a short time, and were happily not productive of any material mischief, having been probably driven by some irregular wind out of their intended course, and weakened by the coolness of the climate.

From a paper published in the 18th volume of the Philosophical Transactions we find, that in the year 1693, swarms of this species of locust settled in some parts of Wales. Two vast flights were observed in the air not far from the town of Dolgalken, in Merionethshire: the others fell in Pembrokeshire. From a letter published in the 38th volume of the same work, it appears, that some parts of Germany, particularly in the march of Brandenburgh, &c. suffered considerable injury from the depredations of these animals. They made their appearance in the spring of the year 1732, from flights which had deposited their eggs in the ground the preceding year. They attacked and devoured the young spike of the wheat, &c. and this chiefly by night, and thus laid waste many acres at a time beyond all hope of recovery. In the 46th volume of the same Transactions we find a description of the ravages of these animals in Wallachia, Moldavia, Transylvania, Hungary, and Poland, in the years 1747 and 1748.

"The first swarms entered into Transylvania in August 1747: these were succeeded by others, which were so surprizingly numerous, that when they reached the Red Tower, they were full four hours in their passage over that place; and they flew so close that they made a sort of noise in the air by the beating of their wings against one another. The width of the swarm was some hundreds of fathoms, and its height or density may be easily imagined to be more considerable, inasmuch as they hid the sun and darkened the sky, even to that degree, when they flew low, that people could not know one another at the distance of twenty paces; but as they were to fly over a river that runs in the valleys of the Red Tower, and could find neither resting-place nor food; being at length tired of their flight, one part of them lighted on the unripe corn on this side of the Red Tower, such as millet, Turkish wheat, &c.; another pitched on a low wood, where, having miserably wasted the produce of the land, they continued their journey, as if a signal had actually been given for a march. The guards of the Red Tower attempted to stop their irruption into Transylvania by firing at them; and indeed, where the balls and shot swept through the swarm, they gave way and divided; but having filled up their ranks in a moment, they proceeded on their journey. In the month of September, some troops of them were thrown to the ground by great rains and other inclemency of the weather, and thoroughly soaked with wet: they crept along in quest of holes in the earth, dung, and straw; where being sheltered from the rains, they laid a vast number of eggs, which stuck together by a viscid juice, and were longer and smaller than what is commonly called an ant's egg (the chrysalis of the formica) very like grains of oats.

In the spring of 1748, certain little blackish worms were seen lying in the fields and among the bushes, sticking together, and collecting in clusters, not unlike the hillocks of moles or ants. As nobody knew what they were, so there was little or no notice taken of them, and in May they were covered by the shooting of the corn sown in winter; but the subsequent June discovered what those worms were; for then, as the corn sown in spring was pretty high, these creatures began to spread over the fields, and become destructive to the vegetables by their numbers. At that time they differed little or nothing from our common grasshoppers; having their head, sides, and back, of a dark colour, with a yellow belly, and the rest of a reddish hue. About the middle of June, according as they were hatched sooner or later, they were generally a finger's length, or somewhat longer, but their shape and colour still continued. Towards the end of June they cast off their outward covering, and then it plainly appeared that they had wings; and as soon as any of them found themselves able to use their wings, they soared up, and by flying round the others, enticed them to join them. Wherever those troops happened to ch, they spared no sort of vegetable: they ate up the young corn, and the very grass; but nothing was more dismal than to behold the lands in which they were hatched; for they so greedily devoured every thing green, before they could fly, that they left the ground quite bare.

"There is nothing to be feared in those places to which this plague did not reach before the autumn; for the locusts have not strength to fly to any considerable distance but in the months of July, August, and the beginning of September; and even then, in changing their places of residence, they seem to tend to warmer climates.

"Different methods are to be employed, according to the age and state of these insects; for some will be effectual as soon as they are hatched, others when they begin to crawl, and others when they begin to fly. It would be of great service to seek out the places where the females lodged; for nothing was more easy than carefully to visit those places in March and April, and to destroy their eggs or little worms with sticks or briars; but in the summer, when they have marched out of their spring-quarters, and have invaded the corn-fields, &c. it is almost impossible to extirpate them without thoroughly thrashing the whole piece of land that harbours them with sticks or flails, and thus crushing the locust with the produce of the land. Finally, when the corn is ripe or nearly so, there is no other method of getting rid of them, or even of diminishing their numbers, than to surround the ground with a multitude of people, who might fright them away with bells, brass vessels, and all other sorts of noise. But even this method will not succeed till the sun is pretty high.

"It will likewise be of use, where a large troop of them has pitched, to dig a long trench, of an ell width and depth, and place several persons along its edges, provided with brooms, while another numerous set of people form a semicircle that takes in both ends of the trench, and encompasses the locusts; and by making the noise above-mentioned, drive them into the trench, out of which if they attempt to escape, those on the edges are to sweep them back, and then crush them with their brooms and stakes, and bury them by throwing in the earth again. But when they have begun to fly, there should be horsemen upon the watch in the fields, who, upon any appearance of the swarm taking wing, should immediately alarm the neighbourhood by a certain signal, that they might come and fright them from their lands by all sorts of noise; and if, tired with flying, they happen to pitch on a waste piece of land, it will be very easy to kill them with sticks and brooms in the evening or early in the morning, while they are wet with the dew; or any time of the day in rainy weather, for then they are not able to fly."

We have before observed, that the locusts which fell in several parts of England, and in particular in the neighbourhood of the metropolis, in the year 1748, were evidently some straggling detachments from the vast flights which in that year visited many of the inland parts of the European continent.

The ravages of locusts in various parts of the world, at different periods, are recorded by numerous authors. In the year 593 of the Christian era, after a great drought, these animals appeared in such vast legions as to cause a famine in many countries. In 677 Syria and Mesopotamia were overrun by them. In 852, immense swarms took their flight from the Eastern regions into the West, flying with such a sound that they might have been mistaken for birds: they destroyed all vegetables, not sparing even the bark of trees and the thatch of houses; and devoured the corn so rapidly, as to destroy, on computation, a hundred and forty acres in a day: their daily marches or distances of flight were computed at twenty miles; and these were regulated by leaders or kings, who flew first, and settled on the spot which was to be visited at the same hour the next day by the whole legion: these marches were always undertaken at sunrise. These locusts were at length driven by the force of winds into the Belgic ocean, and being thrown back by the tide and left on the shores, caused a dreadful pestilence by their smell. In 1271, all the corn-fields of Milan were destroyed; and in the year 1339 all those of Lombardy. In 1541, incredible hosts afflicted Poland, Wallachia, and all the adjoining territories, darkening the sun with their numbers, and ravaging all the fruits of the earth.

2. One of the largest species of locust yet known is the gryllus cristatus of Linnæus, which is five or six times the size of the gryllus migratorius, and, together with some others of the larger kind, is made use of in some parts of the world as an article of food: they are eaten both fresh and salted, in which last state they are publicly sold in the markets of some parts of the Levant. The quantity of edible substance which they afford is but small, especially in the male insects; but the females, on account of the ovaries, afford a more nutritious sustenance.

The gryllus cristatus is a highly beautiful animal; being of a bright red, with the body annulated with black; and the legs varied with yellow: the upper wings tesselated with alternate variegations of dark and pale green; the lower with transverse undulated streaks: the length of the animal from head to tail is about four inches, and the expanse of wings from tip to tip, when fully extended, hardly less than seven inches and a half.

3. Greatly allied to the preceding is the gryllus dux; it is of the same size and general appearance, but has the body

green; the upper wings brown, with the front edge green; and the lower wings red, with numerous black spots disposed in such a manner as to form transverse streaks. It is a native of South America and the West Indian islands.

4. The gryllus viridissimus of Linnæus is one of the largest European species, and is often seen during the decline of summer in our own country. It is wholly of a pale grass-green, with a slight blueish cast on the head and under part of the thorax, which is marked above by a longitudinal reddish-brown line: the length of the insect, from the mouth to the tips of the wings, is about two inches and a half: the female is distinguished by a long sword-shaped process at the end of the body, being the instrument with which she pierces the ground in order to deposit her eggs: it consist of a pair of valves, through the whole length of which the eggs are protruded: they are of an oblong form, and a pale brown colour.

5. The gryllus verrucivorus is also found in some parts of England, and is of an equal size with the viridissimus, but of a reddish-brown colour, with darker variegations: this animal, according to Linnæus, is frequently applied by the people of Sweden to warts on the hands, which it is suffered to bite off, and is said thus to prevent their return.

6. But of all the British insects of this genus the gryllus gryllotalpa or mole-cricket is by far the most curious; and in its colour and manners differs greatly from the rest. It is of an uncouth, and even formidable aspect, measuring more than two inches in length; and is of a broad and slightly flattened shape, of a dusky brown colour, with a ferruginous cast on the under parts, and is readily distinguished by the extraordinary structure of its fore-legs, which are excessively strong, and furnished with very broad feet, divided into several sharp, claw-shaped, segments, with which it is enabled to burrow under ground in the manner of a mole: the lower wings, which when expanded are very large, are, in their usual state, so complicated under the very short and small upper wings or sheaths, that their ends alone appear, reaching, in a sharpened form, along the middle of the back; the abdomen is terminated by a pair of sharp-pointed, lengthened, hairy processes, nearly equalling the length of the antennæ in front, and contributing to give this animal an appearance in some degree similar to that of a blatta.

The mole-cricket emerges from its subterraneous retreats only by night, when it creeps about the surface, and occasionally employs its wings in flight. It prepares for its eggs an oval nest, measuring about two inches in its longest diameter: this nest is situated a hand's breadth below the surface of the ground: it is accurately smoothed within, and is furnished with an obliquely curved passage leading to the surface. The eggs are about two hundred and fifty or three hundred in number, nearly round, of a deep brownish yellow colour, and of the size of common shot: on the approach of winter, or any great change of weather, these insects are said to remove the nest, by sinking it deeper, so as to secure it from the power of frost; and when the spring commences, again raising it in proportion to the warmth of the season, till at length it is brought so near the surface as to receive the full influence of the air and sunshine; but should unfavourable weather again take place, they again sink the precious deposit, and thus preserve it from danger. The eggs are usually deposited in the months of June and July, and the young are hatched in August. At their first exclusion they are about the size of ants, for which, on a cursory view, they might be mistaken; but on a close inspection are easily known by their broad feet, &c. In about the space of a month they are grown to the length of more than a quarter of an inch; in two months upwards of three quarters; and in three months to the length of more than an inch. Of this length they are usually seen during the close of autumn, after which they retire deep beneath the surface; not appearing again till the ensuing spring. During ther growth they cast their skin three or four times.

The mole-cricket lives entirely on vegetables, devouring the young roots of grasses, corn, and various esculent plants, and commits great devastation in gardens. It is found in most parts of Europe, and in the northern parts of Asia and America.

7. The tettigonia or grasshopper, well known in our meadows, belongs to this genus.

8. The acheta or cricket, of which there are two varieties, the hearth and the field cricket.

9. The griseus is found in Italy. (See Plate LXVII. Nat. Hist. fig. 215.)

10. The stridulus inhabits most parts of Europe. (See Plate LXVII. Nat. Hist. fig. 216.)

GRYPHITES, in natural history, in English crow's-stone, an oblong fossil shell, very narrow at the head, and becoming gradually wider to the extremity, where it ends in a circular limb; the head or beak of this is very hooked or bent inward. They are frequently found in their gravel or clay-pits, in many counties. There are three or four distinct species of them; some are extremely rounded and convex on the back, others less so: and the plates of which they are composed, are in some smaller and thinner, in others thicker and larger, in specimens of the same bigness.

GUAIACUM, *lignum vitæ*, or *pockwood;* a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 14th order, gruinales. The calyx is quinquefid and unequal: the petals five, and inserted into the calyx; the capsule is angulated, and trilocular or quinquelocular. The species are 4: 1. The officinale, or common lignum vitæ used in medicine, is a native of the West India islands and the warmer parts of America. (See Pl. LXVII. Nat. Hist. fig. 217.) There it becomes a large tree, having a hard, br [illegible] tle, brownish bark, not very thick. The wood is f[illegible]rm, solid, ponderous, very resinous, of a blackish yello[illegible]w colour in the middle, and of a hot aromatic taste [illegible]. The smaller branches have an ash-coloured bark, a[illegible] divided by pairs of a bright green colour. T[illegible]d leaves are produced in clusters at the end of the br[illegible]ne flowers are composed of oval concave petals of a fine [illegible]anches, and 2. The sanctum, with many pairs of obt[illegible] blue colour. many small lobes placed along the mid-ri[illegible]ase lobes, and darker green colour than those of the [illegible]b by pairs of a The flowers are produced in loose bu[illegible] foregoing sort. end of the branches, and are of a fin[illegible]ches towards the petals fringed on the edges. This sp[illegible]e blue colour, with of the West India islands, where it [illegible]ecies is also a native num vitæ. 3. The afrum, with ma[illegible] is called bastard lig- [illegible]y blunt-pointed leaves,

is a native of the Cape of Good Hope. The plants retain their leaves all the year, but have never yet flowered in this country. 4. The dubium, a native of the South Seas.

The first species can only be propagated by seeds, which must be procured from the countries where it naturally grows. They must be sown fresh in pots, and plunged into a good hotbed, where they will come up in six or eight weeks. While young, they may be kept in a hotbed of tan-bark under a frame during the summer; but in autumn they must be removed into the bark stove, where they should constantly remain. The second sort may be propagated the same way; but the third is to be propagated by layers, and will live all the winter in a good greenhouse.

The wood of the first species is of very considerable use both in medicine and in the mechanical arts. It is so compact and heavy as to sink in water. The outer part is often of a pale-yellowish colour; but the heart is blacker, or rather of a deep brown. Sometimes it is marbled with different colours. It is so hard as to break the tools which are employed in felling it, and is therefore seldom used as fire-wood, but is of great use to the sugar-planters for making wheels and cogs to sugar-mills. It is also frequently wrought into bowls, mortars, and other utensils. It is brought over hither in large pieces of four or five hundred weight each; and from its hardness and beauty is in great demand for various articles of turnery ware.

The wood, gum, bark, fruit, and even the flowers of this tree, have been found to possess medicinal virtues; but it is only the 3 first, and more particularly the wood and resin, which are now in general use in Europe. The wood has little or no smell, except when heated, or while rasping, and then a slight aromatic one is perceived. When chewed, it impresses a mild acrimony, biting the palate and fauces. Its pungency resides in its resinous matter, which it gives out in some degree to water by boiling, but spirit extracts it wholly.

The resin is obtained by wounding the bark in different parts of the body of the tree, or by what has been called jagging. It exudes copiously from these wounds, though gradually; and when a quantity is found accumulated upon the several wounded trees, hardened by exposure to the sun, it is gathered and packed in small kegs for exportation. The resin is of a friable texture, of a deep greenish colour, and sometimes of a reddish hue; it has a pungent acrid taste, but little or no smell unless heated. The tree also yields a spontaneous exudation from the bark, which is called the native gum, and is brought to us in small irregular pieces, of a bright semi-pellucid appearance, and differs from the former in being much purer.

Guaiacum was first introduced into Europe as a remedy for the venereal disease, and appears to have been used in Spain so early as 1508. The great success attending its administration before the proper use of mercury was known, brought it into such repute, that it is said to have been sold for seven old crowns a pound. It did not, however, continue to maintain its reputation; but was found generally to fail where the disease was inveterate, and was at length superseded by mercury, to which it now only serves occasionally as an adjuvant. The general virtues of guaiacum, are those of a warm stimulating medicine, strengthening the stomach and other viscera, and remarkably promoting the urinary and cuticular discharges: hence in cutaneous eruptions, it is deemed eminently useful; as well as in the rheumatism when given in a sufficient dose. The resin is the most active, and the efficacy of the wood, &c. depends upon the quantity of this contained in them. The resin is given from a few grains to a scruple or half a dram, which last dose proves for the most part considerably purgative. Dissolved in spirit of wine, and afterwards combined with water, by means of mucilage or the yolk of egg, or in form of the simple or volatile tincture, it is much employed in gout and chronic rheumatism. These last have been given to the extent of half an ounce twice a day, and are sometimes usefully combined with tincture of opium. See Resins.

GUARDIAN, one appointed by the wisdom and policy of the law, to take care of a person and his affairs, who by reason of his imbecility and want of understanding is incapable of acting for his own interest; and it seems by our law, that his office originally was to instruct the ward in the arts of war, as well as those of husbandry and tillage, that when he came of age he might be the better able to perform those services to his lord, whereby he held his own land. 2 Bac. Abr. 672.

There are several kinds of guardians, as, guardian by nature, guardian by the common law, guardian by statute, guardian by custom, guardian in chivalry, guardian in soccage, and guardian by appointment of the lord chancellor.

Guardian by nature, is the father or mother; and here it should be observed, that by the common law every father has a right of guardianship of the body of his son and heir, until he attains the age of twenty-one years. Co. Lit. 84.

This guardianship extends no further than the custody of the infant's person. 1 Inst. 84.

It yields as to the custody of the person, to guardianship in soccage, where the title to both guardianships concur in the same individuals. 1 Inst. 88 b.

But guardianship in soccage ending at 14, it seems that after that age, the father or other ancestor, having a like title to both guardianships, becomes guardians by nature till the infant's age of 21. Carth. 384.

Lastly, the father may disappoint the mother, and other ancestors, of the guardianship by nature, by appointing a testamentary guardian under the statutes 4 and 5 P. et M. and 12 Car. II.

Guardian by nature, has only the care of the person and education of the infant, and has nothing to do with his lands merely in virtue of his office; for such guardian may be though the infant have no lands at all, which a guardian in soccage cannot. Co. Lit. 88.

Guardian by the common law. If a tenant in soccage dies, his heir being under 14, whether he is his issue or cousin, male or female, the next of blood to the heir, to whom the inheritance cannot descend, shall be guardian of his body and land till his age of fourteen; and although the nature of soccage tenure is in some measure changed from what it originally was, yet it is still called soccage tenure, and the guardian in soccage is still only where lands of that kind, as most of the lands in England now are, descend to the heir within age; and though the heir after 14 may choose his own guardian, who shall con-

tinue till he is 21, yet as well the guardian before 14, as he whom the infant shall think fit to choose after 14, are both of the same nature, and have the same office and employment assigned to them by the law, without any intervention or direction of the infant himself: for they were therefore appointed, because the infant in regard of his minority, was supposed incapable of managing himself and his estate, and consequently derive their authority not from the infant, but from the law: and that is the reason they transact all affairs in their own name, and not in the name of the infant, as they would be obliged to do if their authority was derived from him. Co. Lit. 87.

Hence the law has invested them, not with a bare authority only, but also with an interest till the guardianship ceases; and to prevent their abuse of this authority and interest, the law has made them accountable to the infant, either when he comes to the age of 14 years, or at any time after, as he thinks fit; and therefore are not to have any thing to their own use, as the guardian in chivalry had. Co. Lit. 90. a.

Guardian by statute. By the common law, no person could appoint a guardian, because the law had appointed one, whether the father was tenant by knight service, or in soccage. 3 Co. 37.

The first statute that gave the father a power of appointing, was the 4 and 5 P and M. c. 8. which provides under severe penalties, such as fine and imprisonment for years, that no one shall take away any maid or woman child unmarried, being within the age of sixteen years, out of or from the possession, custody, or governance, and against the will, of the father of such maid or woman child, or of such person or persons to whom the father of such maid or woman child, by his last will and testament, or by any other act in his life-time, has or shall appoint, assign, bequeath, give, or grant the order, keeping, education and government, of such maid or woman child. 1 Sid. 362.

In the construction of this statute, the following opinion has been holden. That a testamentary guardian, or one formed according to this statute, comes in loco parentis, and is the same in office and interest with a guardian in soccage, and differs only as to the modus habendi, or in a few particular circumstances; as first that it may be held for a longer time, viz. till the heir attains the age of 21, whereas before it was but 14; secondly, it may be by other persons held, for before it was the next of kindred not inheritable could have it; and now who the father names shall have it. Vaugh. 178.

Guardian by custom. By the custom of the city of London, the custody and guardianship of orphans under age, unmarried, belongs to the city. 2 Bac. Abr. 675.

By the custom of Kent, where any tenant died, his heir being within age, the lord of the manor might and did commit the guardianship to the next relation within the court of justice in whose jurisdiction the land was; but the lord was bound on all occasions to call him to account, and if he did not see that the accounts were fair, the lord himself was bound to answer it. This province the lord chancellor has taken from inferior courts, only in Kent, where these customs are continued.

Guardian in chivalry. By the common law, if tenant by knight-service had died, his heir male being under the age of twenty-one years, the lord shall have the land holden of him, till such heir had arrived at that age, because till then he was not intended to be able to do such service; and such lord had likewise the custody of the body of the infant, to bring him up, and inure him to martial discipline, and was therefore called guardian in chivalry. Co. Lit. 74. This priviledge of wardship is now abolished.

Guardian in soccage. Guardians in soccage are also called guardians by the common law. Wardship is incident to tenure in soccage, but of a nature very different from that which was formerly incident to knight-service; for if the inheritance descends to an infant under 14, the wardship of him does not, nor ever did, belong to the lord of the fee; because in this tenure, no military or other personal service being required, there was no occasion for the lord to take the profits in order to provide a proper substitute for his infant tenant. Co. Lit. 84.

Guardian by appointment of the lord chancellor. It is not easy to state how this jurisdiction was acquired; it is certainly of no very ancient date, though indisputable: for it is clearly agreed, that the king, as pater patriæ, is universal guardian of all infants, ideots, and lunatics, who cannot take of themselves; and as this care cannot be exercised otherwise than by appointing them proper curators or committees, it seems also agreed, that the king may, as he has done, delegate the authority to his chancellor; and that therefore at this day, the court of chancery is the only proper court, that has jurisdiction in appointing and removing guardians, and in preventing them and others from abusing their persons or estates. 2 Inst. 14. And as the court of chancery is now vested with this authority, hence in every day's practice, we find that court determining, as to the right of guardianship, who is the next of kin, and who the most proper guardian; as also orders are made by that court on petition or motion, for the provision of infants during any dispute therein; as likewise guardians removed or compelled to give security; they and others punished for abuses committed on infants, &c.

Guardian of the spiritualities, the person to whom the spiritual jurisdiction of any diocese is committed, during the time the see is vacant. A guardian of the spiritualities may likewise be either such in law, as the archbishop is of any diocese within his province; or by delegation, as he whom the archbishop or vicar-general for the time appoints. Any such guardian has power to hold courts, grant licences, dispensations, probates of wills, &c.

GUAPERVA. See Chætodon.

GUAREA, a genus of the class and order octandria monogynia. The cal. is four-cleft; pet. four; nect. cylindric, bearing the anthers at its mouth; caps. four-valved, four-celled; seeds solitary. There is one species; a tree of the West Indies.

GUDGEON, in ichthyology. See Cyprinus.

Gudgeons, in a ship, are the eyes drove into the stern-post, into which the pintles of the rudder go, to hang it.

In vol. XI. of the Transactions of the Society for the Encouragement of Arts, &c. we have the following account of a gudgeon on an improved construction for the upright shafts of mills. "This gudgeon is formed of

hard steel, and works on a hard steel bed; is circular, three inches in diameter, and three-fourths of an inch thick: from its upper side a rib projects, which being fixed in the bottom of an upright shaft, the gudgeon works horizontally on a square bed: and that now in the possession of the society has worked in a mill whose wheel and shaft weighed nearly six tons; and though it had continued to work seven years, had lost very little of its surface. It ran in a square box of cast iron, having oil therein: and a notch along the whole of the face of the gudgeon admits the oil to insinuate itself between the gudgeon and the bed."

GUETTARDA, a genus of the heptandria order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. The male calyx is cylindrical; the corolla cleft into seven parts, and funnel-shaped. The female calyx cylindrical; the corolla cleft into seven parts; one pistil, and the fruit a dry plum. There are four species, trees of the East and West Indies.

GUILANDINA, the nickar tree; a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The calyx is monophyllous and salver-shaped; the petals inserted into the neck of the calyx, nearly equal. The seed-vessel a legumen. The species are six; the most remarkable are, 1. The bonduc, or yellow nickar. 2. The bonducella, or grey nickar. These are climbing plants, natives of the West Indies, where they rise to the height of 12 or 14 feet: the flowers come out at the wings of the stalks, and are composed of five concave yellow petals. They are succeeded by pods about three inches long and two broad, closely armed with slender spines, opening with two valves, each inclosing two hard seeds about the size of children's marbles, of a yellowish colour. 3. The moringa, or morunga nickar, is a native of the island of Ceylon, and some places on the Malabar coast. It rises to the height of 25 or 30 feet, having flowers produced in loose bunches from the sides of the branches, and composed of an unequal number of petals.

These plants, being natives of warm climates, require to be kept through the winter in a stove. They are propagated by seeds; but those of the first sort are so hard, that unless they are soaked two or three days in water before they are put into the ground, or placed under the pots in the tan-bed to soften their covers, they will remain for years without vegetating. The roots of the third sort are scraped when young, and used by the inhabitants of Ceylon and Malabar, as those of horse-radish are in Europe. The wood dyes a beautiful blue colour. It is the lignum nephriticum of the dispensatories, and is brought over in large, compact, ponderous pieces, without knots, of a whitish or pale-yellow colour on the outside, and dark-coloured or reddish within: the bark is usually rejected. This wood imparts to water or rectified spirit a deep tincture; appearing, when placed between the eye and the light of a golden-colour, in other situations blue: pieces of another wood are sometimes mixed with it, which give only a yellow colour to water. The nephritic wood has scarcely any smell, and very little taste. It stands recommended in difficulty of urine, and all nephritic complaints, and is said to have this peculiar advantage; that it does not, like the warmer diuretics, heat or irritate the urinary passages. Practitioners, however, have not found these praises warranted by experience.

GUILD (from the Saxon guildan "to pay"), signifies a fraternity or company, because every one was a gildare, that is, to pay something towards the charge and support of the company. As to the original of these guilds or companies, it was a law among the Saxons, that every freeman of fourteen years of age should find sureties to keep the peace, or be committed: upon which certain neighbours, consisting of ten families, entered into an association, and became bound for each other, either to produce him who committed an offence, or to make satisfaction to the injured party: that they might the better do this, they raised a sum of money among themselves, which they put into a common stock; and when one of their pledges had committed an offence, and was fled, then the other nine made satisfaction out of this stock, by payment of money according to the offence. Because this association consisted of ten families, it was called a decennary: and hence proceeded later kinds of fraternities. But as to the precise time when these guilds had their origin in England, there is nothing of certainty to be found; since they were in use long before any formal licence was granted to them for such meetings. It seems to have been about the close of the eleventh century, says Anderson in his History of Commerce, vol. i. p. 70, that merchant-guilds, or fraternities, which were afterwards styled corporations, came first into general use in many parts of Europe. Mr. Madox, in his Firma Burgi, chap. i. § 9. thinks they were hardly known to our Saxon progenitors, and that they might be probably brought into England by the Normans, although they do not seem to have been very numerous in those days. The French and Normans might probably borrow them from the free cities of Italy, where trade and manufactures were much earlier propagated, and where possibly such communities were first in use. These guilds are now companies joined together, with laws and orders made by themselves, by the licence of the prince.

GUILD, in the royal boroughs of Scotland, is still used for a company of merchants, who are freemen of the borough. (See BOROUGH.) Every royal borough has a dean of guild, who is the next magistrate below the baliff. He judges of controversies among men concerning trade; disputes between inhabitants touching buildings, lights, water-courses, and other nuisances; calls courts, at which his brethren of the guild are bound to attend; manages the common stock of the guild; and amerces and collects fines.

GUINEA-PIG. See CAVIA.

GUINEA-WORM. See DRACUNCULUS.

GUITAR, or GUITARRA, a musical instrument of the string-kind, with five double rows of strings, of which those that are bass, are in the middle, unless it be for the burden, an octave lower than the fourth.

GULA, or GOLA. See ARCHITECTURE.

GULES, in heraldry, signifies the colour red, which is expressed in engraving by perpendicular lines falling from the top of the escutcheon to the bottom.

GUM. A thick, transparent, tasteless fluid, which sometimes exudes from certain species of trees. It is

very adhesive, and gradually hardens without losing its transparency; but easily softens again when moistened with water. The gum most commonly used is that which exudes from different species of mimosa, particularly the nilotica. It is known by the name of gum arabic. Gum likewise exudes abundantly from the prunus avium, or common wild cherry-tree of this country.

Gum is usually obtained in small pieces like tears, moderately hard, and somewhat brittle while cold, so that it can be reduced by pounding to a fine powder. When pure it is colourless, but it has usually a yellowish tinge, and it is not destitute of lustre. It has no smell. Its taste is insipid. Its specific gravity varies from 1.31 to 1.48.

1. Gum undergoes no change from being exposed to the atmosphere; but the light of the sun makes it assume a white colour. Water dissolves it in large quantities. The solution which is known by the name of mucilage, is thick and adhesive: it is often used as a paste, and to give stiffness and lustre to linen. When spread out thin it soon dries, and has the appearance of a varnish; but it readily attracts moisture, and becomes glutinous. Water washes it away entirely. When mucilage is evaporated the gum is obtained unaltered. This mucilaginous solution may be kept for years without undergoing putrefaction. Scarcely any vegetable substance is less liable to decomposition. At last, however, the odour of acetic acid becomes perceptible in it.

When gum is exposed to heat it softens and swells, but does not melt; it emits air-bubbles, blackens, and at last, when nearly reduced to charcoal, emits a low blue flame. This flame appears sooner if a flaming substance is held just above the gum. After the gum is consumed, there remains a small quantity of white ashes, composed chiefly of the carbonats of lime and potass.

2. It does not appear that gum is acted upon by oxygen gas. A solution of gum and water, when exposed to the air, soon becomes mouldy on the surface, but undergoes no farther change for a long time. The action of the simple combustibles on gum has scarcely been examined. Azotic gas seems to have no action on it whatever.

Gum does not act upon metals; but it has the property of combining with several of the metallic oxides, and forming compounds: at least, some of the salts occasion precipitates when dropt into solutions of gum. The most curious effect is that produced by the oxymuriat of iron. When this salt, concentrated, is dropt into a very strong mucilage, the whole becomes a brown semitransparent jelly, which is not readily dissolved by water. When dried, the jelly becomes lighter-coloured, and assumes nearly the appearance of gum. Its taste is that of gum mixed with iron.

Liquid potass first converts gum into a substance not unlike curd, and then dissolves it. The solution is of a light amber-colour, and transparent. When long kept, the gum again falls into the state of curd. Alcohol throws down the gum in white flakes still soluble in water; but it retains the potass obstinately, and is much more friable than before. Lime-water and ammonia likewise dissolve gum, and it may be afterwards separated little altered.

Charcoal powder, when mixed with a solution of gum in water, gives it a black colour, which cannot be removed by filtration, unless a very great proportion of the powder is added. In that case the water passes clear; but the whole of the gum is retained by the charcoal. Mr. Lowitz found that not less than 30 lbs. of charcoal powder must be mixed with water containing an ounce of gum dissolved in it, before the water is entirely deprived of the gum.

The vegetable acids dissolve gum without alteration; the strong acids decompose it. Sulphuric acid converts it into water, acetous acid, and charcoal. The same effect is said by Fourcroy to be produced by muriatic acid. But this is not accurate unless some heat is applied. When gum is dissolved in strong muriatic acid, a brown solution is obtained; which becomes perfectly transparent when diluted with water, while at the same time some charry matter falls. If the solution is now saturated with ammonia, evaporated to dryness, and the residue digested in alcohol, the alcohol assumes a deep-brown colour, and dissolves the whole except a very little sal ammoniac. The gum now bears some resemblance to sugar in its properties; at least when heated it melts, and gives out a very strong smell of caromel.

Oxymuriatic acid converts gum into citric acid, according to the experiments of Vauquelin. He passed a current of oxymuriatic acid gas through a diluted solution of gum in water. In a few days almost the whole of the gum was acidified; and he detected citric acid by the formation of citrat of lime, soluble in water, and decomposable by oxalic acid. If nitric acid is slightly heated upon gum till it has dissolved it, and till a little nitrous gas is exhaled, the solution on cooling deposits saclactic acid. Malic acid is formed at the same time; and if the heat is continued, the gum is at last changed into oxalic acid. Thus no less than three acids are developed by the action of nitric acid on gum. We are indebted to Mr. Cruikshank for the most precise experiments on the quantity of oxalic acid obtainable from gum by nitric acid. By digesting 480 grains of it with six ounces of nitric acid, he obtained 210 grains of oxalic acid, and six grains of oxalat of lime.

Gum is insoluble in alcohol. When alcohol is poured into mucilage, the gum immediately precipitates; because the affinity between water and alcohol is greater than that between water and gum. The gum in this case is in the state of soft opaque white flakes. Neither is gum soluble in ether. It is not soluble in oils; but when triturated with a little oil it renders the oil miscible with water.

The action of the hydrosulphurets, sulphurets, phosphurets, and of most of the salts on gum, has not been examined with any attention.

Gum and sugar readily unite together by dissolving both in water. By gentle evaporation a perfectly transparent solid substance is obtained, which does not crystallize. When treated with alcohol it becomes white, opaque, and soft. The greater part of the sugar is dissolved, and the gum remains united to a small portion. It has a sweetish taste, and very much resembles in appearance the substance of which the nests of wasps are formed.

3. When gum is distilled in a retort, the products are

water impregnated with a considerable quantity of pyromucous acid, or acetic acid combined with oil, a little empyreumatic oil, carbonic acid gas, and carbureted hydrogen gas. When the pyromucous acid obtained by the process is saturated with lime, a quantity of ammonia is disengaged with which that acid has been combined. The charcoal which remained in the retort leaves behind it, after incineration, a little lime and phosphat of lime. Mr. Cruikshank, to whom we are indebted for these facts, gradually heated 480 grains of gum arabic to redness in a coated glass retort. The products were,

Pyromucous acid mixed with some oil	210 gr.
Charcoal - - - - - - -	96
Lime and a little phosphat of lime -	10
Carbureted hydrogen and carbonic acid gas	164
Total	480.

The pyromucous acid liquid contained less acid than what was obtained from an equal weight of sugar, in the proportion of 118 to 150. The gases consisted of 93 ounce measures of carbonic acid, and 180 of carbureted hydrogen, composed of 5 parts charcoal to 1 of hydrogen. When the pyromucous acid was saturated with lime, ammonia was disengaged.

From these experiments it follows, that gum contains oxygen, hydrogen, carbon, azote, and lime. The lime may be detected by dropping nitric acid into a solution of gum; needleform crystals of sulphat of lime are slowly deposited. If we compare the products obtained by the distillation of sugar with those obtained from gum, we can scarcely doubt that the latter contains the greater proportion of carbon. As it yields less pyromucous acid, it is not improbable that it also contains less oxygen. Sugar is a triple compound; but gum contains five constituents.

4. The species of gum at present known amount to four; though it is likely that a more rigid examination of the vegetable kingdom will discover a greater number. These are gum arabic, gum tragacanth, cherry-tree gum, and the mucilage which is contained in the roots and leaves of many plants.

Gum arabic exudes from the mimosa nilotica, and other species of mimosa. It is the species described in the preceding part of this article.

5. Gum tragacanth is the produce of the astragalus tragacantha, a thorny shrub which grows in Candia and other islands of the Levant. The gum is said to exude about the end of June from the stem and larger branches, and soon dries in the sun. It is in the state of whitish verniform pieces, not nearly so transparant as gum arabic. It is much stronger than gum arabic, not so easily dissolved in water, and is said to go farther. When Mr. Cruikshank distilled 480 grains of it in a glass retort, he obtained the following products:

Pyromucous acid - - - -	245 gr.
Charcoal - - - - - - -	93
Lime with some phosphat - - -	12
Carbonic acid gas and carbureted hydrogen gas	130
	480

When the pyromucons acid was saturated with lime, a considerable greater proportion of ammonia was disengaged than from the pyromucous acid of gum arabic. The gases were 78 ounce-measures of carbonic acid, and 91 of carbureted hydrogen. Hence we see that gum tragacanth contains more azote and lime, and perhaps more oxygen and less carbon, than gum arabic.

6. The prunus avium, the common cherry and plum trees, and the almond and apricot, likewise yield a gum which exudes in great abundance from natural or artificial openings in the stem. It is of a reddish-brown colour, in large masses, and much softer and more easily melted than gum arabic. But no precise set of experiments has been made to ascertain how far its properties coincide with those of the last two species.

7. Mucilage is contained in the roots and leaves of a vast number of plants. Almost all the bulbous roots and fleshy leaves yield it. For example, the roots of the hyacinthus nondescriptus, and the althea officinalis; the leaves of the altbæra, of tbe malva sylvestris of many of the fuci, and of the greater number of the lichens; the seeds of flax, quinces, fenugrec, &c.

The bulbs of the hyacinth contain so much mucilage, that when dried they may be employed as a substitute for gum arabic. This was first made known to the public by Mr. Willis. A mucilage may be extracted from most of the stringy lichens by water, which likewise answers all the purposes of a solution of gum. This was first discovered by lord Dundonald. The mucilaginous quality of most of the fuci is apparently much greater, though the mucilage obtained from them does not answer so well.

How far the mucilage extracted by water from these plants agrees with gum in its properties, has not been examined with much precision, if we except the mucilage of the hyacinth. From the experiments of Leroux, it appears that the mucilage of that plant is in every respect the same with gum. Tbe bulbs are to be pounded, mixed with five times their weight of water, and subjected to the press. The residue is to be diluted afresh, and again pressed. The liquid thus obtained is to be allowed to repose for some days till it clarifies somewhat, and then evaporated to dryness. The gum remains.

8. It has been remarked by Mr. Barrow, and probably also by others, that all the plants which yield gum have an astringent bark. This rule, however, does not hold with respect to mucilage. Almost all the trees known to yield gum have been enumerated in the preceding part of this article. To attempt a list of all the plants containing mucilage, would, in the present state of our knowledge, be superfluous, even if it was possible. It exists most abundantly in young plants, and gradually disappears as they arrive at perfection. It forms a great proportion of the leaves and roots of many eatable plants.

9. Gum is a nutritive food, though seldom employed for that purpose, except when in the state of mucilage. It is used frequently as a paste, and to give stiffness or lustre to linen. The calico-printers use it in great quantities to give their colours such a degree of consistency as prevents them from running upon the cloth. It forms an ingredient in ink for a similar reason. In medicine it forms the base of many mixtures.

Gum-resins. This class of vegetable substances has been long distinguished by physicians and apothecaries. It contains many active substances much employed in medicine; and they certainly possess a sufficient num-

ber of peculiar properties to entitle them to be ranked apart. Unfortunately these substances have not yet attracted much of the attention of chemists. Their properties and constituents of course are but imperfectly ascertained. They may, however, be distinguished by the following characters.

They are usually opaque, or at least their transparency is inferior to that of the resins. They are always solid, and most commonly very brittle, and have sometimes a fatty appearance.

When heated they do not melt as the resins do, neither are they so combustible. Heat, however, commonly softens them, and causes them to swell. They burn with a flame. They have almost always a strong smell, which in several instances is alliaceous. Their taste also is often acrid, and always much stronger than that of the resins. They are partially soluble in water; but the solution is always opaque, and usually milky.

Alcohol dissolves only a portion of them. The solution is transparent; but when diluted with water it becomes milky; yet no precipitate falls, nor is any thing obtained by filtring the solution. Vinegar and wine likewise dissolves them partially; and the solution, like the aqueous, is opaque or milky.

The action of alkalies on them has been examined only by Mr. Hatchett. All of them tried by that celebrated chemist dissolved readily in alkaline solutions when assisted by heat. We may therefore consider them as soluble in alkalies like resins. Mr. Hatchett also found them acted on by nitric acid, and dissolved by it just as the resinous bodies.

The specific gravity is usually greater than that of the resins. Their other properties still continue unknown. They all either exude spontaneously from plants, or are obtained by incisions. At first they seem to be in a liquid state; but they gradually harden when exposed to the air and weather.

They have been usually considered by chemists as composed of gum and resin; but their properties are not consistent with that supposition. They all contain a volatile oil, or a substance intermediate between an oil and resin. To this substance we are to ascribe the milky solution which they form with water. The other constituent, in most cases, bears a much closer resemblance to extractive than to gum; perhaps, then, we shall not err very far, if we consider the gum-resins as composed of a gum or an extractive substance, and a body intermediate between oil and resin; to which last they owe their most peculiar properties.

The gum-resins which have been hitherto applied to any useful purpose are chiefly the following:

1. *Galbanum*. It is obtained from the bubon galbanum, a perennial plant, and a native of Africa. When this plant is cut across a little above the root, a milky juice flows out, which soon hardens and constitutes galbanum. It is brought from the Levant in small pieces composed of tears, agglutinated together of a yellowish or white colour. Its taste is acrid and bitter, and its smell peculiar. Water, vinegar, and wine, dissolve most of it, but the solution is milky. Alcohol acts but feebly; when distilled it yields volatile oil in considerable quantity. Its specific gravity is 1.2.

2. *Ammoniac*. This substance is brought from the East Indies. Nothing certain is known concerning the plant which yields it; though from analogy it has been suspected to be a species of ferula. It is in small pieces and has a yellowish-white colour. Its smell is somewhat like that of galbanum, but more pleasant; its taste is a nauseous sweet mixed with bitter. It does not melt. Water dissolves a portion of it; the solution is milky, but gradually lets fall a resinous portion. One-half is soluble in alcohol. It seems then to contain resin completely formed: specific gravity is 1.2. Mr. Hatchett found it soluble in alkalies.

3. *Olibanum*, is obtained from the juniperus lycia, and is chiefly collected in Arabia. It is the frankincense of the ancients; it is in transparent brittle masses about the size of a chesnut. Its colour is yellow. It has little taste; and when burnt diffuses an agreeable odour. Alcohol dissolves it; and with water it forms a milky liquid. When distilled it yields a little volatile oil. Its specific gravity is 1.173.

4. *Sagapanum*. The plant which yields this gum-resin is not well known: but it is suspected to be the ferula persica. The substance itself is brought to Europe from Alexandria. It is commonly in tears agglutinated together: colour yellow; taste hot and bitter; smell alliaceous; softens between the fingers, but does not melt when heated: sparingly soluble in water, but almost completely soluble in alcohol. When distilled it yields a volatile oil.

5. *Asafœtida*. This substance is obtained from the ferula asafœtida, a perennial plant which is a native of Persia. When the plant is about four years old, its roots are dug up and cleaned. Their extremity being then cut off, a milky juice exudes, which is collected. Then another portion is cut off, and more juice exudes. This is continued till the roots are exhausted. The juice thus collected soon hardens, and constitutes asafœtida. It is brought here in small grains of different colours, whitish, reddish, violet, brown: pretty hard, but brittle: its taste is acrid and bitter; its smell strongly alliaceous and fœtid. It is imperfectly soluble both in alcohol and water; but, like the other gum-resins, has been but carelessly analysed. Its specific gravity is 1.327.

6. *Scammony*. This substance is obtained from the convolvulus scammonia, a climbing plant which grows in Persia. The roots when cut yield a milky juice; this when collected and allowed to harden constitutes scammony. Colour, dark grey; smell, peculiar and nauseous; taste, bitter and acrid: with water it forms a greenish coloured opaque liquid. Alcohol dissolves the greatest part of it; it is usually mixed with the expressed juice of the root, and frequently also with other impurities, which alter its appearance. In medicine it operates as a strong cathartic. Its specific gravity is 1.235.

7. *Opoponax*. This substance is obtained from the pastinaca opoponax, a plant which is a native of the countries round the Levant. The gum resin, like most others, is obtained by wounding the roots of the plant. The milky juice when dried in the sun constitutes the opoponax. It is in lumps of a reddish yellow colour, and white within; smell peculiar; taste bitter and acrid; with water it forms a milky solution. Its specific gravity is 1.622.

8. *Gamboge*, or *gumgutt*. This substance is obtained from the stalagmitis cambogioides, a tree which grows

GUN

wild in the East Indies. In Siam it is obtained in drops by wounding the shoots; in Ceylon it exudes from wounds of the bark. It is brought to Europe in large cakes. Its colour is yellow; it is opaque, brittle, and breaks vitreous; it has no smell, and very little taste; with water it forms a yellow turbid liquid. Alcohol dissolves it almost completely: and when mixed with water it becomes turbid, unless the solution contains ammonia; in that case acids throw down an insoluble yellow precipitate. It operates, when taken internally, as a most violent cathartic; its specific gravity is 1.221. It appears that it was taken to Europe by the Dutch about the middle of the 17th century.

9. *Myrrh.* The plant from which this substance is obtained is unknown; if we believe Bruce, it belongs to the genus of Mimosa. It grows in Abyssinia and Arabia: it is in the form of tears; colour reddish-yellow; when pure som ewhat transparent, but it is often opaque: odour peculiar: taste bitter and aromatic: does not melt when heated, and burns with difficulty. With water it forms a yellow opaque solution: the solution in alcohol becomes opaque when mixed with water, but no precipitate appears: by distillation it yields oil: its specific gravity is 1.360; it is employed in medicine: Mr. Hatchett found it soluble in alkalies.

10. *Euphorbium.* This substance is obtained from the euphorbia officinalis. The milky juice which exudes from that plant, when dried in the sun, constitutes euphorbium: it is brought from Africa in small yellow tears; it has no smell, and is mostly soluble in alcohol: its specific gravity is 1.124. It is considered as poisonous.

11. Little is known concerning the substances called bdellium and caranna, reckoned among the gum-resins. The specific gravity of the first is 1.371, of the second 1.124. Bdellium was celebrated by the ancient physicians: it comes from Arabia. The substance extracted from ivy, and known by the name of gummi hederæ, is considered as a gum-resin. Its specific gravity is 1.294.

12. From the experiments made upon ipecacuanha, the root of the cephelis ipecacuanha, especially by Dr. Irvine, we learn that it also contains a gum-resin. The same remark applies to several other vegetable substances employed in medicine.

It deserves attention, that the gum-resins, when subjected to destructive distillation, yield all of them a portion of ammonia; a proof that they all contain azote. In this respect they agree with gum and extractives.

GUM-ELASTIC. See CAOUTCHOUC.

GUINEA, a gold coin struck in England. The value or rate of the guinea has varied. It was at first equal to 20 shillings; but by the scarcity of gold it was afterwards advanced to 21s. 6d.; though it is now sunk to 21s. The pound weight troy of gold is cut into 44 parts and a half, and each part makes a guinea, which is therefore equal to $\frac{2}{89}$lb. or $\frac{24}{89}$ oz. or 5 dwts. $9\frac{39}{89}$ gr. This coin took its name, guinea, from the circumstance of the gold of which it was at first struck being brought from that part of Africa called Guinea, for which reason also it bore the impression of an elephant.

GUN, a fire-arm, or weapon of offence, which forcibly discharges a ball or other matter through a cylindrical tube, by means of inflamed gunpowder.

The word gun now includes most of the species of fire arms; mortars and pistols being almost the only kind excepted from this denomination. They are divided into great and small guns; the former including all that are usually called cannon, ordnance, or artillery; and the latter including muskets, firelocks, carabines, musquetoons, blunderbusses, fowling-pieces, &c.

The first hint of the invention of guns is in the works of Roger Bacon, who flourished in the 13th century. In a treatise written by him about the year 1280, he proposes to apply the violent explosive force of gunpowder for the destruction of armies. And though it is certainly known that the composition of gunpowder is described by Bacon in the same work, yet the invention has usually, though improperly, been ascribed to Bartholdus Schwartz, a German monk, who it is said discovered it only in the year 1320; and the invention is related in the following manner: Schwartz having, for some purpose, pounded nitre, sulphur, and charcoal together, in a mortar, which he afterwards covered imperfectly with a stone, a spark of fire accidentally fell into the mortar, which setting the mixture on fire, the explosion blew the stone to a considerable distance. Hence it is probable that Schwartz might be taught the simplest method of applying it in war; for it rather seems that Bacon conceived the manner of using it to be by the violent effort of the flame unconfined, and which is indeed capable of producing astonishing effects. And the figure and name of mortars given to a species of old artillery, and their employment, in throwing large stone bullets at an elevation, very much favour this conjecture.

When, or by whom, guns were first made, is uncertain. It is known, however, that the Venetians used cannon at the siege of Claudia Jessa, now called Chioggia, in 1366, which were brought thither by two Germans, with some powder and leaden balls; as likewise in their wars with the Genoese in 1379. But before that, king Edward the Third made use of cannon at the battle of Cressy, in 1346, and at the seige of Calais, in 1347. Cannon were employed by the Turks at the siege of Constantinople, then in possession of the Christians, in 1394, and in that of 1452, which threw a weight of 100lb.; but they commonly burst at the first, second, or third firing. Louis the XIth had one cast at Tours, of the same size, which threw a ball from the Bastille to Charenton: one of these extraordinary cannon was taken at the siege of Dieu, in 1546, by don John de Castro, and is now in the castle of St. Julien de Borra, 10 miles from Lisbon; the length of it is 20 feet 7 inches, its diameter at the middle 6 feet 3 inches, and it threw a ball of 100lb. weight. It has neither dolphins, rings, nor button; is of an unusual kind of metal; and it has a large Indostan inscription upon it, which says it was cast in 1400.

Cannon take their names from the weight of the proper ball. Thus, a piece that discharges a cast-iron ball of 24 pounds, is called a 24-pounder; one that carries a ball of 12 pounds, is called a 12-pounder; and so of the rest, divided into the following sorts, viz.

Ship-guns, consisting of 42, 36, 32, 24, 18, 12, 9, 6, and 3 pounders.

Garrison-guns, of 42, 32, 24, 18, 12, 9, and 6 pounders.

Battering-guns, of 24, 18, and 12 pounders.

Field-pieces, of 12, 9, 6, 3, 2, $1\frac{1}{2}$, 1, and $\frac{1}{2}$ pounders.

Mortars, it is thought, have been at least as ancient as cannon. They were employed in the wars of Italy, to throw balls of red-hot iron, stones, &c. long before the invention of shells.

Mr. Malter, an English engineer, first taught the French the art of throwing shells, which they practised at the siege of Motte in 1634. The method of throwing red-hot balls out of mortars was first certainly put in practice at the siege of Stralsund in 1675 by the elector of Brandenburgh; though some say in 1653, at the siege of Bremen.

Another species of ordnance has been long in use, by the name of howitzer, which is a kind of medium as to its length, between the cannon and mortar, and is a very useful piece, for discharging either shells or large balls, which is done either at point blank, or at a small elevation.

A new species of ordnance has lately been introduced by the Carron company, and thence called a carronade, which is only a very short howitzer, and which possesses the advantage of being very light and easy to work.

The species of guns before-mentioned, are now made chiefly of cast-iron; except the howitzer, which is of brass, as well as some cannon and mortars.

Muskets were first used at the siege of Rhege, in the year 1521. The Spaniards were the first who armed part of their foot with these weapons. At first they were very heavy, and could not be used without a rest. They had matchlocks, and did execution at a great distance. On their march the soldiers carried only the rests and ammunition, having boys to bear their muskets after them. They were very slow in loading, not only from the unwieldiness of their pieces, and because they carried the ball and powder separate, but from the time it took to prepare and adjust the match; so that their fire was not near so brisk as ours is now. Afterwards a lighter matchlock musket come in use; and they carried their ammunition in bandeliers, to which were hung several little cases of wood covered with leather, each containing a charge of powder. The muskets with rests were used as late as the beginning of the civil wars in the time of Charles the First. The lighter kind succeeded them, and continued till the beginning of the present century, when they also were disused, and the troops throughout Europe armed with firelocks. These are usually made of hammered iron.

GUNDELIA, a genus of the class and order syngenesia polygamia segregata. There is scarcely any calyx; what there is, is 5-flowered; cor. tubular, male and hermaphrodite; recept. chaffy; down none. There is one species, a herb of the Levant, having the habit of a thistle.

GUNNERA, a genus of the class and order gynandria, diandria. The character is, ament. with 1-flowered scales; calyx and corolla none: germen, 2-toothed; styles 2; seed one. There is one species, a herb of the Cape.

GUNNERY, the art of charging, directing, and exploding fire-arms, as cannon, mortars, muskets, &c. to the best advantage.

Gunnery is sometimes considered as a part of the military art, and sometimes as a part of pyrotechny. To the art of gunnery too belongs the knowledge of the force and effect of gunpowder, the dimensions of the pieces, and the proportions of the powder and ball they carry, with the methods of managing, charging, pointing, spunging, &c.

The first application of gunpowder to military affairs, it seems, was made soon after the year 1300, for which the proposal of friar Bacon, about the year 1280, for applying its enormous explosion to the destruction of armies, might give the first hint; and Schwartz, to whom the invention of gunpowder has been erroneously ascribed, on account of the accident above-mentioned under the article GUN, might have been the first who actually applied it in this way.

The first species of artillery, however, which were charged with gunpowder and stone bullets of a prodigious size, were of very clumsy and inconvenient structure and weight. Thus, when Mahomet the 2d besieged Constantinople, in 1453, he battered the walls with stones of this kind, and with pieces of the calibre of 1200 pounds; which could not be fired more than four times a day.

For the last 200 years, the formation of cannon has been very little improved: the battering cannon now approved, are those that were formerly called demi-cannon, carrying a ball of 24 pounds weight; this weight having been found fully sufficient. The method also of making a breach, by first cutting off the whole wall as low as possible before its upper part is attempted to be beaten down, seems to be a considerable modern improvement in the practical part of gunnery; but the most considerable improvement in the practice, is the method of firing with small quantities of powder, and elevating the piece but a little, so that the bullet may just go clear of the parapet of the enemy, and drop into their works, called ricochet firing: for by this means the ball, coming to the ground at a small angle, and with a small velocity, does not bury itself, but bounds or rolls along a great way, destroying all before it.

The Italians were the first people that made any attempts to ascertain the theory of projectiles, which they did about the beginning of the 16th century. It was then determined, that the greatest range of a shot was when discharged at an elevation of 45 degrees; and that no part of the path described by a ball is a right line. See PROJECTILES.

Mr. Robins informs us, in the preface to his New Principles of Gunnery, that he had met with no more than four authors who had treated experimentally on this subject. The first of these is Collado, in 1642, who has given the ranges of a falconet, carrying a three-pound shot, to every point of the gunner's quadrant, each point being the 12th part, or 7 degrees and a half. But from his numbers it is manifest that the piece was not charged with its usual allotment of powder.

It is extraordinary that before Mr. Robins, there were but four authors who had treated experimentally on gunnery, and these to little purpose; but the treatise of Mr. Robins is still regarded as the foundation of the science.

The first thing considered by him, and which is indeed the foundation of all other particulars relating to gunnery, is the explosive force of gunpowder. The intensity of this force Mr. Robins ascertained in different ways. One of these is by firing the powder in the air, thus: A small quantity of the powder is placed in the upper part of a glass tube, and the lower part of the tube is immerg-

ed in water, the water being made to rise so near the top, that only a small portion of air is left in that part where the powder is placed; in this situation the communication between the upper part of the tube and the external air being closed, the powder is fired by means of a burning-glass, or otherwise; the water descends upon the explosion, and stands lower in the tube than before, by a space proportioned to the quantity of powder fired. Another was by firing the powder in vacuo, viz. in an exhausted receiver, by dropping the grains of powder upon a hot iron excluded in the receiver. For the result of these experiments, see GUNPOWDER.

Having determined the force of the gunpowder, or intensity of the agent by which the projectile is to be urged, Mr. Robins next determined the effects it will produce, or the velocity with which it will impel a shot of a given weight from a piece of ordnance of given dimensions; which is a problem strictly limited, and perfectly soluble by mathematical rules, and is in general this: Given the first force, and the law of its variation, to determine the velocity with which it will impel a given body in passing through a given space, which is the length of the bore of the gun.

In the solution of this problem, Mr. Robins assumes these two postulates, viz. 1. That the action of the powder on the bullet ceases as soon as the bullet is out of the piece; and 2d. That all the powder of the charge is fired and converted into elastic fluid before the bullet is sensibly moved from its place: assumptious which for good reasons are found to be in many cases very near the truth. It is to be noted also, that the law by which the force of the elastic fluid varies, is this; viz. that its intensity is directly as its density, or reciprocally proportional to the space it occupies, being so much the stronger as the space is less; a principle well known, and common to all elastic fluids. Upon these principles then Mr. Robins resolves this problem, by means of the 39th proposition of Newton's Principia, in a direct way, and the result is equivalent to this theorem, where the quantities are expressed by algebraic symbols; viz. the velocity of the ball

$$v = 27130 \sqrt{\frac{10a}{cd} \times \log. \frac{b}{a}}.$$

$$\text{or} = 100 \sqrt{\frac{223ad^2}{w} \times \log. \frac{b}{a}}; \text{ whence}$$

v is the velocity of the ball,
a the length of the charge of powder,
b the whole length of the bore,
c the specific gravity of the ball, or weight of a cubic foot of the same matter in ounces,
d the diameter of the bore,
w the weight of the ball in ounces.

For example. Suppose $a = 2\frac{5}{8}$ inc., $b = 45$ inc., $c = 11345$ oz. for a ball of lead, and $d = \frac{3}{4}$ inc.; then $v = 27130 \sqrt{\frac{7}{2269} \times \log. \frac{120}{7}} = 1674$ feet per second, the velocity of the ball.

Or, if the weight of the bullet be $w = 1\frac{9}{20}$ oz. $= \frac{29}{20}$ oz. Then $x = 100 \sqrt{\frac{1115 \times 189}{29 \times 32} \times \log. \frac{120}{7}} = 1674$ feet, as before,

"Having in this proposition," says Mr. Robins, "shown how the velocity, which any bullet acquires from the force of powder, may be computed upon the principles of the theory laid down in the preceding propositions; we shall next show, that the actual velocities, with which bullets of different magnitudes are impelled from different pieces, with different quantities of powder, are really the same with the velocities assigned by these computations; and consequently, that this theory of the force of powder, here delivered, does unquestionably ascertain the true action and modification of this enormous power.

"But in order to compare the velocities communicated to bullets by the explosion, with the velocities resulting from the theory by computation, it is necessary that the actual velocities with which bullets move, should be capable of being discovered, which yet is impossible to be done by any methods hitherto made public. The only means hitherto practised by others for that purpose, have been either by observing the time of the flight of the shot through a given space; or by measuring the range of the shot at a given elevation, and thence computing, on the parabolic hypothesis, what velocity would produce this range. The first method labours under this insurmountable difficulty, that the velocities of these bodies are often so swift, and consequently the time observed is so short, that an imperceptible error in that time may occasion an error in the velocity thus found, of 2, 3, 4, 5, or 600 feet in a second. The other method is so fallacious, from the resistance of the air (to which inequality the first is also liable), that the velocities thus assigned may not be perhaps the tenth part of the actual velocities sought.

"To remedy then these inconveniences, I have invented a new method of finding the real velocities of bullets of all kinds; and this to such a degree of exactness (which may be augmented too at pleasure), that in a bullet moving with a velocity of 1700 feet in 1″, the error in the estimation of it need never amount to its 500th part; and this without any extraordinary nicety in the construction of the machine."

Mr. Robins then gives an account of the machine by which he measures the velocities of the balls, which machine is simply this; viz. a pendulous block of wood suspended freely by a horizontal axis, against which block are to be fired the balls whose velocities are to be determined.

"This instrument thus fitted, if the weight of the pendulum is known, and likewise the respective distances of its centre of gravity, and of its centre of oscillation, from its axis of suspension, it will thence be known what motion will be communicated to this pendulum by the percussion of a body of a known weight moving with a know degree of celerity, and striking it in a given point; that is, if the pendulum is supposed at rest before the percussion, it will be known what vibration it ought to make in consequence of such a determined blow; and, on the contrary, if the pendulum, being at rest, is struck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the striking body may thence be determined.

"Hence then, if a bullet of a known weight strikes the pendulum, and the vibration which the pendulum makes in consequence of the stroke is ascertained, the velocity with which the ball moved is thence to be known."

Mr. Robins then explains his method of computing velocities from experiments with this machine; which method is rather troublesome and perplexed, as well as the rules of Euler and Antoni, who followed him in this business: but a much simpler rule is given in Dr. Hutton's Tracts, vol. i. p. 119, where the experiments are explained at full length, and this rule is expressed by either of the two following formulas: $v = 5.6727cg \times \frac{p+b}{bir} \sqrt{o} = 614.58cg \times \frac{p+b}{birn}$, the velocity; where v denotes the velocity of the ball when it strikes the pendulum, p the weight of the pendulum, b the weight of the ball, c the chord of the arc described by the vibration to the radius r, g the distance below the axis of motion to the centre of gravity, o the distance to the centre of oscillation, i the distance to the point of impact, and n the number of oscillations the pendulum will perform in one minute, when made to oscillate in small arcs. The latter of these two theorems is much the easiest, both because it is free of radicals, and because the value of the radical $\sqrt{o}$, in the former, is to be first computed from the number x, or number of oscillations the pendulum is observed to make.

Soon after the first publication of Robins's New Principles of Gunnery, in 1742, the learned in several other nations, treading in his steps, repeated and farther extended the same subject, sometimes varying and enlarging the machinery; particular Euler in Germany, D'Antoni in Italy, and Messrs. D'Arcy and Le Roy in France: but most of these, like Mr. Robins, with small fire-arms, such as muskets and fusils.

But in the year 1775, in conjunction with several able officers of the Royal Artillery, and other ingenious gentlemen, Dr. Hutton undertook a course of experiments with the ballistic pendulum, in which the machinery was extended to cannon-shot of 1, 2, and 3 pounds weight. An account of these was published in the Philos. Trans. for 1778, "and for which," says the Dr., "the Royal Society honoured me with the prize of the gold medal. These were the only experiments that I know of which had been made with cannon-balls for this purpose, although the conclusions to be deduced from such, are of the greatest importance to those parts of natural philosophy which are dependant on the effects of fired gunpowder; nor do I know of any other practical method of ascertaining the initial velocities within any tolerable degree of the truth. The knowledge of this velocity is of the utmost consequence in gunnery; by means of it, together with the law of the resistance of the medium, every thing is determinable relative to that business; for, besides its being an excellent method of trying the strength of different sorts of powder, it gives us the law relative to the different quantities of powder, to the different weights of shot, and to the different lengths and sizes of guns. Besides these, there does not seem to be any thing wanting to answer any inquiry that can be made concerning the flight and ranges of shot, except the effects arising from the resistance of the medium. In these experiments the weights of the pendulums employed were from 300 to near 600 pounds." In that paper is described the method of constructing the machinery, of finding the centres of gravity and oscillation of the pendulum, and of making the experiments, which are all set down in the form of a journal, with all the minute and concomitant circumstances; as also the investigation of the new and easy rule, set down just above, for computing the velocity of the ball from the experiments. The charges of powder were varied from 2 to 8 ounces, and the shot from 1 to near 3 pounds. And from the whole were clearly deduced these principal inferences: viz.

"1. First, That gunpowder fires almost instantaneously. 2. That the velocities communicated to balls or shot, of the same weight, by different quantities of powder, are nearly in the subduplicate ratio of those quantities; a small variation, in defect, taking place when the quantities of powder became great. 3d. And when shot of different weights are employed, with the same quantity of powder, the velocities communicated to them are nearly in the reciprocal subduplicate ratio of their weights. 4. So that, universally, shot which are of different weights, and impelled by the firing of different quantities of powder, acquire velocities which are directly as the square roots of the quantities of powder, and inversely as the square roots of the weights of the shot, nearly. 5. It would therefore be a great improvement in artillery, to make use of shot of a long form, or of heavier matter; for thus the momentum of a shot, when fired with the same weight of powder, would be increased in the ratio of the square root of the weight of the shot. 6. It would also be an improvement to diminish the windage; for by so doing, one-third or more of the quantity of powder might be saved. 7. When the improvements mentioned in the last two articles are considered as both taking place, it is evident that about half the quantity of powder might be saved, which is a very considerable object. But important as this saving may be, it seems to be still exceeded by that of the article of the guns; for thus a small gun may be made to have the effect and execution of another two or three times its size in the present mode, by discharging a shot of two or three times the weight of its natural ball or round shot. And thus a small ship might discharge shot as heavy as those of the greatest now made use of.

"Finally, as the above experiments exhibit the regulations with regard to the weights of powder and balls, when fired from the same piece of ordnance, &c.; so by making similar experiments with a gun, varied in its length, by cutting off from it a certain part before each course of experiments, the effects and general rules for the different lengths of guns may be certainly determined by them. In short, the principles on which these experiments were made, are so fruitful in consequences, that, in conjunction with the effects resulting from the resistance of the medium, they seem to be sufficient for answering all the inquiries of the speculative philosopher, as well as those of the practical artillerist."

GUNPOWDER, a composition of nitre, sulphur, and charcoal, mixed together, and usually granulated.

It appears that Roger Bacon knew of gunpowder. He tells us, in his Treatise De Secretis Operibus Artis et Naturæ, et de Nullitate Magiæ, cap. 6, which is supposed by some to have been published at Oxford in 1216, "that from saltpetre and other ingredients, we are able to make a fire that shall burn at what distance we please." And Dr. Plott, in his History of Oxfordshire, p. 236,

assures us that these "other ingredients were explained in a MS. copy of the same treatise, in the hands of Dr. G. Langbain, and seen by Dr. Wallis, to be sulphur and wood-coal."

As to the preparation of gunpowder, there are various compositions of it, with respect to the proportions of the three ingredients, to be met with in pyrotechnical writings; but the process of making it up is much the same in all.

For some time after the invention of artillery, gunpowder was of a much weaker composition than that now is use. But when guns of modern structure were introduced, gunpowder of the same composition as the present came also into use. In the time of Tartaglia the cannon-powder was made of 4 parts of nitre, one of sulphur, and one of charcoal: and the musket-powder of 48 parts of nitre, 7 parts of sulphur, and 8 parts of charcoal; or of 18 parts of nitre, 2 parts of sulphur, and 3 parts of charcoal; the modern composition is,

76	parts nitre
15	charcoal
9	sulphur
100	

These ingredients are first reduced to a fine powder separately, then mixed intimately, and formed into a thick paste with water. After this has dried a little, it is placed upon a kind of sieve full of small holes, through which it is forced. By that process it is divided into grains, the size of which depends upon the size of the holes through which they have been squeezed. The powder, when dry, is put into barrels, which are made to turn round on their axes. By this motion the grains of gunpowder rub against each other, their asperities are worn off, and their surfaces are made smooth. The powder is then said to be glazed.

Gunpowder, as is well known, explodes violently when a red heat is applied to it. This combustion takes place even in a vacuum; a vast quantity of gas is emitted, the sudden production of which is the cause of all the violent effects which this substance produces. Their combustion is evidently owing to the decomposition of the nitre by the charcoal and sulphur. The products are carbonic acid gas, azotic gas, sulphurous acid gas, and probably sulphureted hydrogen. Mr. Cruikshank has ascertained that no perceptible quantity of water is formed. What remains after the combustion is potass combined with a small portion of carbonic acid, sulphat of potass, a very small proportion of sulphuret of potass, and unconsumed charcoal. This mixture soon attracts moisture, and the sulphuret which it contains enables it to act strongly on metallic bodies.

To make gunpowder duly, regard is to be had to the purity or goodness of the ingredients, as well as the proportions of them; for the strength of the powder depends much on that circumstance, and also on the due working or mixing of them together.

To purify the nitre, by taking away the fixt or common salt, and earthy part. Dissolve it in a quantity of hot water over the fire; then filtrate it through a flannel bag, into an open vessel, and set it aside to cool, and to crystallize. These crystals may in like manner be dissolved and crystallized again; and so on, till they become quite pure and white. Then put the crystals into a dry kettle over a moderate fire, which gradually increase till it begins to smoke, evaporate, lose its humidity, and grow very white: it must be kept continually stirring with a ladle, lest it should return to its former figure, by which its greasiness would be taken away; after that, so much water is to be poured into the kettle as will cover the nitre; and when it is dissolved, and reduced to the consistency of a thick liquor, it must be continually stirred with a ladle till all the moisture is again evaporated, and it is reduced to a dry and white meal.

The like regard is to be had to the sulphur; choosing that which is in large lumps, clear and perfectly yellow; not very hard, nor compact, but porous; nor yet too much shining; and if, when set on fire, it freely burns all away, it is a sign of its goodness; so likewise, if it is pressed between the two iron plates that are hot enough to make it run, and in the running appear yellow, and that which remains of a reddish colour, it is then fit for the purpose. But in case it is foul, it may be purified in this manner; melt the sulphur in a large iron ladle or pot, over a very gentle coal-fire, well kindled, but not flaming; then scum off all that rises on the top, and swims upon the sulphur; take it presently after from the fire, and strain it through a double linen cloth, letting it pass leisurely; so will it be pure, the gross matter remaining behind in the cloth.

For the charcoal, the third ingredient, such should be chosen as is large, clear, and free from knots, well burnt, and cleaving. The charcoal of light woods is mostly preferred, as of willow, and that of the branches or twigs of a moderate thickness, as of an inch or two in diameter. Dogwood is now much esteemed for this purpose. And a method of charring the wood in a large iron cylinder has lately been recommended, and indeed proved, as yielding better charcoal than formerly.

The charcoal not only concurs with the sulphur in supplying the inflammable matter, which causes the detonation of the nitre, but also greatly adds to the explosive power of it by the quantity of carbonic acid gas, expelled during its combustion.

These three ingredients, in their purest state, being procured, long experience has shown that they are then to be mixed together in the proportion before-mentioned, to have the best effect.

But it is not the due proportion of the materials only, which is necessary to the making of good powder; another circumstance, not less essential, is the mixing them well together; if this is not effectually done, some parts of the composition will have too much nitre in them, and others too little; and in either case there will be a defect of strength in the powder.

After the materials have been reduced to fine dust, they are mixed together, and moistened with water, or vinegar, or urine, or spirit of wine, &c. and then beaten together with wooden pestles for 24 hours, either by hand, or by mills, and afterwards pressed into a hard, firm, solid cake. When dry, it is grained or corned, which is done by breaking the cake of powder into small pieces, and so running it through a sieve; by which means the grains may have any size given them, according to the nature of the sieve employed, either finer or coarser; and thus also the dust is separated from the grains, and again

mixed with other manufacturing powder, or worked up into cakes again.

Powder is smoothed, or glazed, as it is called, for small arms, by the following operation: a hollow cylinder or cask is mounted on an axis, turned by a wheel; this cask is half-filled with powder, and turned for six hours; and thus by the mutual friction of the grains of powder it is smoothed, or glazed. The fine mealy part, thus separated or worn off from the rest, is again granulated.

The nature, effects, &c. of powder. When the powder is separated as above, if the least spark is struck upon it from a steel and flint, the whole will immediately inflame, and burst out with extreme violence. The effect is not hard to account for: the charcoal part of the grain upon which the spark falls, catching fire like tinder, the sulphur and nitre are readily melted, and the former also breaks into flame; the contiguous grains at the same time undergoing the same fate.

The explosion of gun-powder therefore arises from the violent action, by which all the mixture being quickly and vehemently heated, is rarefied and converted into gas and vapour; which vapour, by the violence of that action becoming so hot as to shine, appears in the form of a flame.

To understand the force of gunpowder, it must be considered that, whether it is fired in a vacuum or in air, it produces by its explosion permanently elastic fluids. It also appears from experiment, that the elasticity or pressure of the fluids produced by the firing of gunpowder is, cæteris paribus, directly as its density.

To determine the elasticity and quantity of the elastic fluids produced from the explosion of a given quantity of gunpowder, Mr. Robins premises, that the elasticity of the fluids increases by heat, and diminishes by cold, in the same manner as that of the air; and that the density of this fluid, and consequently its weight, are the same with the weight of an equal bulk of air, having the same elasticity and the same temperature. From these principles, and from the experiments by which they are established, he concludes that the fluid produced by the firing of gunpowder is nearly three-tenths of the weight of the generating powder itself; and that the volume or bulk of this air or fluid, when expanded to the rarity of common atmospheric air, is about 244 times the bulk of the powder.

Hence it appears, that any quantity of powder fired in any confined space, which it adequately fills, exerts at the instant of its explosion against the sides of the vessel containing it, and the bodies it impels before it, a force at least 244 times greater than the elasticity of common air, or, which is the same thing, than the pressure of the atmosphere; and this without considering the great addition arising from the violent degree of heat with which it is endued at that time; the quantity of which augmentation is the next head of Mr. Robins's inquiry. He determines that the elasticity of the air is augmented in a proportion somewhat greater than that of 4 to 1, when heated to the extremest heat of red-hot iron; and supposing that the flame of fired gunpowder is not of a less degree of heat, increasing the former number a little more than four times, makes nearly 1000; which shows that the elasticity of the flame, at the moment of explosion, is about 1000 times stronger than the elasticity of common air, or than the pressure of the atmosphere. But, from the height of the barometer, it is known that the pressure of the atmosphere upon every square inch, is on a medium $14\frac{3}{4}$lb.; and therefore 1000 times this, or 14750lb. is the force or pressure of the flame of gunpowder, at the moment of explosion, upon a square inch, which is very nearly equivalent to six tons and a half.

This great force, however, disminishes as the fluid dilates itself, and in that proportion, viz. in proportion to the space it occupies, it being only half the strength when it occupies a double space, one-third the strength when triple the space, and so on.

Mr. Robins farther supposes the degree of heat abovementioned to be a kind of medium heat; but that in the case of large quantities of powder the heat will be higher, and in very small quantities lower; and that therefore in the former case the force will be somewhat more, and in the latter somewhat less, than 1000 times the force of the atmosphere.

He farther found that the strength of powder is the same in all variations in the density of the atmosphere, but that the moisture of the air has a great effect upon it; for the same quantity which in a dry season would discharge a bullet with a velocity of 1700 feet in one second, will not in damp weather give it a velocity of more than 12 or 1300 feet in a second, or even less, if the powder is bad, and negligently kept. Farther, as there is a certain quantity of water which, when mixed with powder, will prevents its firing at all, it cannot be doubted that every degree of moisture must abate the violence of the explosion; and hence the effects of damp powder are not difficult to account for.

It is to be observed, that the moisture imbibed by powder does not render it less active when dried again. Indeed, if powder is exposed to very great damps without any caution, or when common salt abounds in it, as often happens through negligence in refining the nitre, in such cases the moisture it embibes may perhaps be sufficient to dissolve some part of the nitre; which is a permanent damage that no drying can retrieve. But when tolerable care is taken in preserving powder, and the nitre it is composed of has been well purged from common salt, it will retain its force for a long time; and it is said that powder has been known to have been preserved for 50 years without any apparent damage from its age.

The velocity of expansion of the flame of gunpowder, when fired in a piece of artillery, without either bullet or other body before it, is prodigiously great, viz. 7000 feet per second, or upwards, as appears from the experiments of Mr. Robins. But Mr. Bernouilli and Mr. Euler suspect it is still much greater. Perhaps, indeed, it may not be less, at the moment of explosion, than four times as much.

It is this prodigious celerity of expansion of the flame of fired gunpowder, which is its peculiar excellence, and the circumstance in which it so eminently surpasses all other inventions, either ancient or modern; for as to the momentum of these projectiles only, many of the warlike machines of the ancients produced in this a degree far surpassing that of our heaviest cannon-shot or shells; but the great celerity given to these bodies cannot be in the least approached by any other means but the flame of powder. The best means of proving gunpowder

is that of the pendulum, already described under the article GUNNERY.

To recover damaged powder. The method of the powder-merchants is this: they put part of the powder on a sailcloth, to which they add an equal weight of what is really good; then with a shovel they mingle it well together, dry it in the sun, and barrel it up, keeping it in a dry and proper place.

Others again, if it is very bad, restore it by moistening it with vinegar, water, urine, or brandy; then they beat it fine, sift it, and to every pound of powder add an ounce, or an ounce and a half, or two ounces (according as it is decayed), of melted nitre; and afterwards these ingredients are to be moistened and well mixed, so that no particular substance may be discerned: which may be known by cutting the mass, and then they granulate it as usual.

In case the powder is quite spoiled, the only thing to be done is to extract the salt-petre with water, in the usual way, by boiling, filtrating, evaporating, and crystallizing; and then, with fresh sulphur and charcoal, to make it up afresh.

GUNPOWDER *and combustibles, laws concerning.* No person shall make gunpowder but in the regular manufactories established at the time of making the stat. 12 Geo. III. c. 61. or licensed by the sessions, pursuant to certain provisions, under forfeiture of the gunpowder, and 2*s.* per lb. nor are pestle-mills to be used under a similar penalty.

Only 40 lbs. of powder to be made at one time under one pair of stones, except Battle-powder, made at Battle and elsewhere in Sussex.

Not more than 40 cwt. to be dried at one time in one stove; and the quantity only required for immediate use to be kept in or near the place of making, except in brick or stone magazines, 50 yards at least from the mill.

Not more than 25 barrels to be carried in any land carriage, nor more than 200 barrels by water, unless going by sea or coastwise, each barrel not to contain more than 100lbs.

No dealer to keep more than 200lbs. of powder, nor any person not a dealer, more than 50lbs. in the cities of London and Westminister, or within three miles thereof, or within any other city, borough, or market-town, or one mile thereof, or within two miles of the king's palaces or magazines, or half a mile of any parish-church, on pain of forfeiture; and 2*s.* per lb. except in licensed mills, or to the amount of 300 lbs. for the use of collieries, within 200 yards of them.

GUN-SMITHERY, the business of a gun-smith or the art of making fire-arms of the smaller sort, as muskets, fowling-pieces, pistols, &c. The principal part of these instruments is the barrel, which ought to have the following properties: 1. Lightness, that it may incommode the person who carries it as little as possible. 2. Sufficient strength, and other properties requisite to prevent its bursting by a discharge. 3. It ought to be constructed in such a manner as not to recoil with violence. And, 4. it ought to be of sufficient length to carry the shot to as great a distance as the force of the powder employed is capable of doing.

The manufacture of fire-arms is now carried to such a degree of perfection by different European nations, that it may perhaps be justly doubted whether any farther improvement in the requisites just mentioned can be made. For the materials the softest iron that can be procured is to be employed. The best in this country are formed of stubs, as they are called, or old horse-shoe nails; which are procured by gun-smiths from farriers, and from poor people who subsist by picking them up on the great roads leading to London. These are sold at about ten shillings per cwt. and 28 pounds are requisite to form a single musket-barrel. The method of manufacturing them from this material is as follows: A hoop of about an inch broad, and six or seven inches diameter, is placed in a perpendicular situation, and the stubs, previously well cleaned, piled up in it with their heads outermost on each side, till the hoop is quite filled and wedged tight with them. The whole then resembles a rough circular cake of iron; which being heated to a white heat, and then strongly hammered, coalesces into one solid lump. The hoop is now removed, and the beatings and hammerings repeated till the iron is rendered very tough and close in the grain; when it is drawn out into pieces of about 24 inches in length, half an inch or more in breadth, and half an inch in thickness. It is, however, not easy to conceive how old stubs can be procured sufficient to supply iron for the number of barrels which go under this denomination. Nor do we, upon any principles of science, see any farther advantage to be derived from this manufacture, than that nail-iron is generally the best of iron, and well hammered.

Four of the pieces, prepared as has been described, are required for one barrel; but in the ordinary way a single bar of the best soft iron is employed. The workmen begin with hammering out this into the form of a flat ruler, having its length and breadth proportioned to the dimensions of the intended barrel. By repeated heating and hammering this plate is turned round a tempered iron-rod called a mandril, the diameter of which is considerably smaller than the intended bore of the barrel. One of the edges of the plate being laid over the other about half an inch, the whole is heated and welded by two or three inches at a time, hammering it briskly, but with moderate strokes, upon an anvil which has a number of semicircular furrows in it, adapted to the barrels of different sizes. Every time the barrel is withdrawn from the fire, the workman strikes it gently against the anvil once or twice in an horizontal direction. By this operation the particles of the metal are more perfectly consolidated, and every appearance of a seam in the barrel is obliterated. The mandril being then again introduced into the cavity of the barrel, the latter is very strongly hammered upon it in one of the semicircular hollows of the anvil, by small portions at a time; the heatings and hammerings being repeated until the whole barrel has undergone the operation, and its parts rendered as perfectly continuous as if they had been formed out of a solid piece. To effect this completely, three welding heats are necessary when the very best iron is made use of, and a greater number for the coarser kinds. The French workmen imagine that by giving the barrel, while in the fire, slight horizontal strokes with the hammer, so as to communicate a vibratory motion to the iron, those particles are thrown off which are in a state of fusion, and cannot easily be con-

verted into malleable iron: but considering the great number of operations already described which the metal has undergone, we can scarcely suppose this to be of much consequence.

The next operation in forming the barrels is the boring of them, which is done in the following manner: Two beams of oak, each about six inches in diameter, and six or seven feet long, are placed horizontally, and parallel to one another; having each of their extremities mortised upon a strong upright piece about three feet high, and firmly fixed. A space of three or four inches is left between the horizontal pieces, in which a piece of wood is made to slide by having at either end a tenon let into a groove which runs on the inside of each beam throughout its whole length. Through this sliding piece a strong pin or bolt of iron is driven or screwed in a perpendicular direction, having at its upper end a round hole large enough to admit the breech of the barrel, which is secured in it by means of a piece of iron that serves as a wedge, and a vertical screw passing through the upper part of the hole. A chain is fastened to a staple in one side of the sliding piece which runs between the two horizontal beams; and passing over a pulley at one end of the machine, has a weight hooked on to it. An upright piece of timber is fixed above this pulley, and between the ends of the beams, having its upper end perforated by the axis of an iron crank furnished with a square socket; the other axis being supported by the wall, or by a strong post, and loaded with a heavy wheel of cast iron to give it force. The axes of this crank are in a line with the hole in the bolt already mentioned. The borer being then fixed into the socket of the crank, has its other end, previously well oiled, introduced into the barrel, whose breech part is made fast in the hole of the bolt: the chain is then carried over the pulley, and the weight hooked on; the crank being then turned with the hand, the barrel advances as the borer cuts its way, till it has passed through the whole length. The boring bit consists of an iron-rod somewhat longer than the barrel, one end of which fits the socket of the crank; the other is adapted to a cylindrical piece of tempered steel, about an inch and a half in length, having its surface cut after the manner of a perpetual screw, with five or six threads, the obliquity of which is very small. The breadth of the furrows is the same with that of the threads, and their depth sufficient to let the metal cut by the threads pass through them easily. Thus the bit gets a strong hold of the metal; and the threads, being sharp at the edges, scoop out and remove all the inequalities and roughness from the inside of the barrel, and render the cavity smooth and equal throughout. A number of bits, each a little larger than the former, are afterwards successively passed through the barrel in the same way, until the bore has acquired the magnitude intended. By this operation the barrel is very much heated, especially the first time the borer is passed through it, by which means it is apt to warp. To prevent this in some measure, the barrel is covered with a cloth kept constantly wetted, which not only preserves the barrel from an excess of heat, but likewise preserves the temper of the bit from being destroyed. The borer itself must also be withdrawn from time to time; both to clean it from the shavings of the metal and to oil it, or repair any damages it may have sustained. Every time a fresh bit has been passed through the barrel, the latter must be carefully examined, to see if it has warped: and likewise if there are any spots, by the workmen called *blacks*, on its inside. When warped, it must be straightened on the anvil, for which a few slight strokes on the convex parts will be sufficient; and this is termed *setting-up* the barrel. When black spots are perceived, the corresponding part on the outside must be marked, and driven in by gentle strokes with the hammer, when they will be completely removed by passing the borer another time through the piece.

The equality of the bore is of the utmost consequence to the perfection of a barrel; insomuch that the greatest possible accuracy in every other respect will not make amends for any deficiency in this. The method used by gunsmiths to ascertain this is by a cylindrical plug of tempered steel highly polished, about an inch in length, and fitting the bore exactly. This is screwed upon the end of an iron-rod, and introduced into the cavity of the barrel, where it is moved backwards and forwards; and the places where it passes with difficulty being marked, the boring bit is repeatedly passed until it moves with equal ease through every part. Any person who wishes to know the merit of his piece in this respect, may do it with tolerable accuracy by means of a plug of lead cast on a rod of iron; or even by a musket-ball filed exactly to the bore, and pushed through the barrel by a ramrod; taking care, however, not to use much force lest the ball be flattened, and its passage thus rendered difficult.

The first tool employed in forming the breech-screw is a plug of tempered steel, somewhat conical, with the threads of a male screw upon its surface, and by the workmen termed a *screw-tap*. This being introduced into the barrel, and worked from left to right and back again, until it has marked out the first four threads of the screw, another less conical tap is introduced: and when this has carried the impression of the screw as far as it is intended to go, a third one, nearly cylindrical, is made use of, scarcely differing from the plug of the breech intended to fill the screw thus formed in the barrel. The plug itself has its screw formed by means of a screw-plate of tempered steel, with several female screws, corresponding with the taps employed for forming that in the barrel. Seven or eight threads are a sufficient length for a plug; they ought to be neat and sharp, so as completely to fill the turns made in the barrel by the tap. The breech-plug is then to be case-hardened, or to have its surface converted into steel, by covering it with shavings of horn, or the parings of the hoofs of horses, and keeping it for some time red-hot, after which it is plunged in cold water.

Thus the common barrels, for the purpose especially of sporting, are made; but there are some other methods of manufacture, by which the barrels are made to differ in some respects from those just described, and are thought to be considerably improved. One kind of these are called *twisted* barrels; and by the English workmen are formed out of the plates made of *stubs*, as above described. Four of these, of the size already mentioned, are requisite to make one barrel. One of them, heated red-hot for five or six inches, is turned like a corkscrew, by means of the hammer and anvil; the remaining parts be-

ing treated successively in the same manner until the whole is turned into a spiral, forming a tube, the diameter of which corresponds with the bore of the intended barrel. Four are generally sufficient to form a barrel of the ordinary length, *i. e.* from 32 to 38 inches: and the two which form the breech or strongest part, called the *reinforced part,* are considerably thicker than those which form the muzzle, or fore part of the barrel. One of these tubes is then welded to a part of an old barrel to serve as an handle; after which the turns of the spiral are united by heating the tube two or three inches at a time to a bright white heat, and striking the end of it several times against the anvil in a horizontal direction with considerable strength, which is called *jumping the barrel;* and the heats given for this purpose are called *jumping heats.* The next step is to introduce a mandril into the cavity, and to hammer the heated portion lightly, in order to flatten the ridges or burrs raised by the jumping at the place where the spirals are joined. As soon as one piece is jumped throughout its whole length, another is welded to it, and treated in the same manner, until the four pieces are united, when the part of the old barrel is cut off, as being no longer of any use. The welding is repeated three times at least, and is performed exactly in the same manner as directed for plain barrels; and the piece may afterwards be finished according to the directions already given.

The advantages of twisted barrels are, after all, somewhat problematical; where there is so much of welding, and that in a spiral form, the welding is more likely to be done in a careless manner, or with some imperfection in some part, than when it is a plain and obvious business: nor have we observed that twisted barrels are less liable to burst than plain ones, where the latter have been well and carefully forged.

The Spanish barrels have been long held in great estimation; yet as the Spanish iron is universally allowed to be unusually good, it is probable that the superiority of their barrels is owing more to the goodness of the materials than to the skill of the workmen. It must be observed, however, that instead of making the plates overlap *a little* in the place where they join, they give one of them a complete turn; so that every Spanish barrel may be said to be double throughout its whole length. The different portions of the iron are also forged in such a manner, that the grain of the iron is disposed in a spiral manner; whence it has the same effect with a ribbon or twisted barrel. The outside is finished by turning them in a lathe; whence probably they are always less elegantly wrought than the French and English pieces. The great value put upon them is also thought to be more owing to fancy than to any real good qualities they possess. Formerly they were made from three to three feet and a half long; their bore being such as to admit a bullet from 22 to 24 in the pound, and their weight from three to three pounds and a half. The reinforced part extends two-fifths of the length; and at 10 or 12 inches from the breech is placed a sight, such as is usually put upon rifle-barrels, or those intended only for ball. According to Espinas, arquebuss-bearer to Philip IV. the weight of a Spanish barrel ought to be four pounds and a half when the length is 42 inches; but both in weight and length they are now much reduced, and seldom exceed the dimensions already mentioned.

The principal imperfections to which gun-barrels are liable, are the chink, crack, and flaw. The first is a small rent in the direction of the length of the barrel; the second across it; and the third is a kind of scale or small plate adhering to the barrel by a narrow base, from which it spreads out like the head of a nail from its shank, and when separated, leaves a pit or hollow in the metal. The chink or flaw are of much worse consequence than the crack in fire-arms, the force of the powder being exerted more upon the circumference than the length of the barrel. The flaw is much more frequent than the chink, the latter scarcely ever occurring but in plain barrels formed out of a single plate of iron, and then only when the metal is deficient in quality. When flaws happen on the outside they are of no great consequence; but in the inside they are apt to lodge moisture and foulness which corrode the iron, and thus the cavity enlarges continually till the piece bursts. This accident, however, may arise from many other causes besides the defect of the barrel itself. The best pieces will burst when the ball is not sufficiently rammed home, so that a space is left between it and the powder. A very small windage or passage for the inflamed powder between the sides of the barrel and ball will be sufficient to prevent the accident; but if the ball has been forcibly driven down with an iron ramrod, so as to fill up the cavity of the barrel very exactly, the piece will almost certainly burst, if only a very small space is left between it and the powder; and the greater the space is, the more certainly does the event take place. A piece will frequently burst from having its mouth stopped up with earth or snow; which accident sometimes happens to sportsmen in leaping a ditch, in which they have assisted themselves with their fowling-piece, putting the mouth of it to the ground; and when this did not happen, it is only to be accounted for from the stoppage being extremely slight. For the same reason a musket will certainly burst if it is fired with the muzzle immersed only a very little way in water. It will also burst from an overcharge; but when such an accident happens in other circumstances, it is most probably to be attributed to a defect in the workmanship, or in the iron itself. These defects are principally an imperfection in the welding, a deep flaw having taken place, or an inequality in the bore; which last is the most common of any, especially in the low-priced barrels. The reason of a barrel's bursting from an inequality in the bore is, that the elastic fluid, set loose by the inflammation of the powder, and endeavouring to expand itself in every direction, being repelled by the stronger parts, acts with additional force against the weaker ones, and frequently bursts through them, which it would not have done had the sides been equally thick and strong throughout. With regard to defects arising from the bad quality of the iron, it is impossible to say any thing certain. As the choice of the materials depends entirely on the gunsmith, the only way to be assured of having a barrel made of proper metal is to purchase it from an artist of known reputation, and to give a liberal price for the piece.

The recoil of a piece becomes an object of importance only when it is very great; for every piece recoils in some degree when it is discharged. The most frequent cause of an excessive recoil is an inequality in the bore of the barrel; and by this it will be occasioned even when the

inequality is too small to be perceived by the eye. The explanation of this upon mechanical principles indeed is not very easy: for as it is an invariable law, that action and reaction are equal to one another, we should be apt to suppose that every time a piece is discharged it should recoil with the whole difference between the velocity of the bullet and that of the inflamed powder. The cause to which too great a recoil in muskets has been usually attributed, is the placing of the touch-hole at some distance from the breech-plug; so that the powder is fired about the middle, or towards its fore part, rather than at its base. To avoid this some artists form a groove or channel in the breech-plug as deep as the second or third turn of the screw; the touch-hole opening into this channel, and thus firing the powder at its very lowest part. It appears, however, from a number of experiments made upon this subject by M. le Clerc, that it made very little difference with regard to the recoil, whether the touch-hole was close to the breech, or an inch distant from it. The only circumstance to be attended to with respect to its situation therefore is, that it be not quite close to the breech-plug: as in such a case it is found to be more apt to be choked up than when placed about a quarter of an inch from it.

The only other circumstance now to be determined with regard to musket-barrels is their proper length. Formerly it was supposed that the longer they were made, the greater would be the distance to which they carried the shot, and that without any limitation. This opinion continued to prevail till about half a century ago, when it was first proposed as a doubt whether long barrels carried farther than short ones. With regard to cannon, indeed, it had long before this time been known that they might be made too long; and Balthazar Killar, a celebrated cannon-founder in the reign of Louis XIV. was able to account for it. When asked by Mons. Suriry de St. Remy, why the culverin of Nancy, which is 22 feet long, did not carry a ball equally far with a shorter piece, he replied, that "the powder, when inflamed, ought to quit the cavity of the piece in a certain time, in order to exert its whole force upon the bullet; by a longer stay part of the force is lost; and the same cause may produce an inequality in the shots, by giving a variation to the bullet, so as to destroy its rectilineal course, and throw it to one side or other of the mark." Mr. Robins informs us, that "if a musket-barrel, of the common length and bore, is fired with a leaden bullet and half its weight of powder, and if the same barrel is afterwards shortened one-half, and fired with the same charge, the velocity of the bullet in this shortened barrel will be about one-sixth less than what it was when the barrel was entire; and if, instead of shortening the barrel, it is increased to twice its usual length, when it will be near eight feet long, the velocity of the bullet will not be augmented more than one-eighth part. And the greater the length of the barrel is in proportion to the diameter of the bullet, and the smaller the quantity of powder, the more inconsiderable will these alterations of velocity be." From these considerations it appears, that the advantages gained by long barrels are by no means equivalent to the disadvantages arising from the weight and incumbrance of using them; and from a multitude of experiments it is now apparent, that any one may choose what length he pleases, without any sensible detriment to the range of his piece. The most approved lengths are from 30 to 36 inches.

An opinion has generally prevailed among sportsmen, that by some unknown manœuvre the gunsmith is able to make a piece, loaded with small shot, throw the contents so close together, that even at the distance of 40 or 50 paces the whole will be confined within the breadth of a hat. From such experiments as have been made on this subject, however, it appears, that the closeness or wideness with which a piece throws its shot is liable to innumerable variations from causes which no skill in the gunsmith can possibly reach. So variable are these causes, that there is no possibility of making the same piece throw its shot equally close twice successively. In general, however, the closer the wadding is, the better disposed the shot seems to be to fall within a small compass. In firing with small shot a curious circumstance sometimes occurs, viz. that the grains, instead of being equally distributed over the space they strike, are thrown in clusters of 10, 12, 15, or more; whilst several considerable spaces are left without a grain in them. Sometimes one-third or one-half of the charge will be collected into a cluster of this kind; nay, sometimes, though much more rarely, the whole charge will be collected into one mass, so as to pierce a board near an inch thick at the distance of 40 or 45 paces. Small barrels are said to be more liable to this clustering than large ones; and M. de Marolles informs us, that this is especially the case when the barrels are new, and likewise when they are fresh-washed; though he acknowledges that it did not always happen with the barrels he employed even after they were washed. It is probable, therefore, that the closeness of the shot depends on some circumstance relative to the wadding rather than to the mechanism of the barrel.

Gun-shot wounds are attended with much worse consequences than wounds made by sharp instruments; for the parts are more shattered and torn, especially when the shot falls upon the joints, bones, or any considerable part. See Surgery.

GUNTER'S Chain, the chain in common use for measuring land, according to the true or statute measure; so called from Mr. Gunter, its reputed inventor.

The length of the chain is 66 feet, or 22 yards, or four poles of five yards and a half each; and it is divided into 100 links, of 7.92 inches each.

This chain is the most convenient of any thing for measuring land, because the contents thence computed are so easily turned into acres. The reason of which is, that an acre of land is just equal to 10 square chains, or 10 chains in length and one in breadth, or equal to 100,000 square links. Hence the dimensions being taken in chains, and multiplied together, it gives the content in square chains; which therefore being divided by 10, or a figure cut off for decimals, brings the content to acres: after which the decimals are reduced to roods and perches, by multiplying by 4 and 40. But the better way is to set the dimensions down in links as integers, considering each chain as 100 links; then, having multiplied the dimensions together, producing square links, divide these by 100,000, that is, cut off five places for

decimals, the rest are acres, and the decimals are reduced to roods and perches as before.

Ex. Suppose, in measuring a rectangular piece of ground, its length be 795 links,
and its breadth 480 links,

63600
3180

Ac. 3.81600
4

Ro. 3.264
40

Per. 10.560

So the content is 3 acres 3 roods 10 perches.

GUNTER'S LINE, a logarithmic line, usually graduated upon scales, sectors, &c.

It is also called the line of lines, and line of numbers; being only the logarithms graduated upon a ruler, which therefore serves to solve problems instrumentally in the same manner as logarithms do arithmetically. It is usually divided into a hundred parts, every tenth of which is numbered, beginning with 1, and ending with 10; so that if the first great division, marked 1, stand for one-tenth of any integer, the next division, marked 2, will stand for two-tenths; 3, three-tenths, and so on; and the intermediate divisions will, in like manner, represent 100 parts of some integer. If each of the great divisions represent 10 integers, then will the lesser divisions stand for integers; and if the great divisions be supposed each 100, the subdivisions will be each 10.

USE OF GUNTER'S LINE.

1. *To find the product of two numbers.* From 1 extend the compasses to the multiplier; and the same extent, applied the same way from the multiplicand, will reach to the product. Thus if the product of 4 and 8 be required, extend the compasses from 1 to 4 and that extent laid from 8 the same way, will reach to 32, their product.

2. *To divide one number by another.* The extent from the divisor to unity will reach from the dividend to the quotient: thus to divide 36 by 4, extend the compasses from 4 to 1, and the same extent will reach from 36 to 9, the quotient sought.

3. *To three given numbers, to find a fourth proportional.* Suppose the numbers 6, 8, 9; extend the compasses from 6 to 8, and this extent, laid from 9 the same way, will reach to 12, the fourth proportional required.

4. *To find a mean proportional between any two given numbers.* Suppose 8 and 32: extend the compasses from 8 in the left-hand part of the line, to 32 in the right; then bisecting this distance, its half will reach from 8 forward, or from 32 backward, to 16, the mean proportional sought.

5. *To extract the square root of any number.* Suppose 25: bisect the distance between 1 on the scale and the point representing 25; then the half of this distance, set off from 1, will give the point representing the root 5. In the same manner the cube root, or that of any higher power, may be found by dividing the distance on the line, between 1 and the given number, into as many equal parts as the index of the power expresses; then one of those parts, set from 1, will find the point representing the root required.

GUNTER'S QUADRANT, one made of wood, brass, &c. containing a kind of stereographic projection of the sphere, on the plane of the equinoctial; the eye being supposed placed in one of the poles.

Besides the use of this quadrant in finding heights and distances, it serves also to find the hour of the day, the sun's azimuth, and other problems of the globe.

GUNTER'S SCALE, usually called by seamen *the Gunter*, is a large plane scale, having various lines upon it, of great use in working the cases or questions in navigation.

This scale is usually two feet long, and about an inch and a half broad, with various lines upon it, both natural and logarithmic, relating to trigonometry, navigation, &c.

On one side are the natural lines, and on the other the artificial or logarithmic ones. The former side is first divided into inches and tenths, and numbered from 1 to 24 inches, running the whole length near one edge. One-half the length of this side consists of two plane diagonal scales, for taking off dimensions to three places of figures. On the other half or foot of this side are contained various lines relating to trigonometry, in the natural numbers, and marked thus, viz.

Rumb, the rumb or points of the compass;
Chord, the line of chords;
Sine, the line of sines;
Tang. the tangents;
S. T. the semitangents; and at the other end of this half are,
Leag. leagues, or equal parts;
Rumb. another line of rumbs;
M. L. miles of longitude;
Chor. another line of chords.

Also in the middle of this foot are *L.* and *P.* two other lines of equal parts. And all these lines on this side of the scale serve for drawing or laying down the figures to the cases in trigonometry and navigation.

On the other side of the scale are the following artificial or logarithmic lines, which serve for working or resolving those cases, viz.

S. R. the sine rumbs;
T. R. the tangent rumbs;
Numb. line of numbers;
Sine. sines;
V. S. the versed sines;
Tang. the tangents;
Meri. meridional parts;
E. P. equal parts.

GUN-WALE, or GUNNEL, is the uppermost wale of a ship, or that piece of timber which reaches on either side from the quarter-deck to the forecastle, being the uppermost bend which finishes the upper works of the hull, in that part in which are put the stanchions which support the waste-trees.

GUSSET, in heraldry, is formed by a line drawn from the dexter or sinister chief points, and falling down perpendicularly to the extreme base. The gusset is an abatement of honour, denoting an effeminate person.

GUSTAVIA, a genus of the polyandria order, in the

monadelphia class of plants. There is no calyx; the petals very numerous; the berry multilocular; the seeds appendaged. There is one species, a tree of Surinam.

GUTTÆ. See ARCHITECTURE.

GUTTA-SERENA, a disease in which the patient, without any apparent fault in the eye, is entirely deprived of sight. See SURGERY.

GUTTY, in heraldry, a term used when any thing is charged or sprinkled with drops. In blazoning, the colour of the drops is to be named, as gutty of sable, of gules, &c.

GUY, in a ship, is any rope used for keeping off things from bearing or falling against the ship's sides when they are hoisting in. That rope which at one end is made fast to the foremast, and seized to a single block at the pendant of the garnet, is called the guy of the garnet.

GUZES, in heraldry, roundles of a sanguine or murry colour. These, from their bloody hue, are by some supposed to represent wounds.

GYMNANTHES, a genus of the class and order monœcia monadelphia. The male has an ament naked; perianthium and corolla none; stamina pedicles, three-parted or three-forked, anther bearing. The female has an ament or germ pedicelled; corolla none; style trifid: capsule tricoccous, three-celled. There are two species, shrubs of the West Indies.

GYMNETRUS, a genus of fishes, of the order of thoracici. The generic character is, body extremely long, compressed; teeth numerous, subulate; gill membrane, four or five-rayed; anal fin wanting. The most remarkable species are:

1. Gymnetrus Ascanii, or ascanian gymnetrus. This extraordinary fish is a native of the northern seas, and seems to have been first described by professor Ascanius, in his work entitled Icones rerum Natularium, &c. The length of the specimen was ten feet, and the diameter, which was equal throughout the whole length, about six inches: the head short, the mouth small, and the eyes rather large: on the upper part of the head, before the commencement of the dorsal fin, were situated 7 or 8 upright naked rays or processes, of moderate length: the dorsal fin, which was rather shallow, commenced at a small distance beyond these, and running along the whole length of the back, formed by its continuation the tail-fin: the ventral fins, if they can be said to deserve the name, consisted of a pair of extremely long single rays or processes terminated by a small ovate expanded tip or finny extremity: the gill-covers appeared to consist of five or six radiated laminæ: the colour of the whole body was bright silver, with a blueish cast diffused over the upper part of the back: the lateral line was strongly marked, and ran from the gill-covers to the tail, and the sides of the body were marked by several longitudinal double rows of slightly extant, very small dusky specks; the forehead was white; the fins pale brown.

This fish is said to be generally seen either preceding or accompanying the shoals of herrings in the northern seas, for which reason it is popularly known by the title of king of the herrings.

2. Blochian gymnetrus. This which is a native of the Indian seas, and which appears also to be occasionally seen in those of Europe, is described by Dr. Bloch from a drawing communicated by J. Hawkins, Esq. In its general appearance it is much allied to the preceding kind, but appears to be furnished with two pair of ventral processes, which are of considerable length, and terminate in large, dilated, finny extremities, of an oval form: the back-fin is continued as far as the tail. The colour of this species is silvery, with a blueish cast on the upper parts, and several transverse, alternate, brownish shades continued along the body, accompanied by large, distant, round spots, of a similar colour: the fins and processes deep crimson: the pectoral fins pretty large in proportion.

It appears from a print published in the year 1798, that a specimen of this fish was thrown on the coast of Cornwall in the month of February in the same year. Its length was eight feet six inches, its breadth in the widest part ten inches and a half, and its thickness only two inches and three quarters; the tail in this specimen was wanting; the colours the same as the specimen figure by Dr. Bloch.

GYMNOSOPHISTS, a sect of philosophers who clothed themselves no farther than modesty required. There were some of these sages in Africa; but the most celebrated clan of them was in India. The African gymnososophists dwelt upon a mountain in Ethiopia, near the Nile, without the accommodation of either house or cell. They did not form themselves into societies like those of India, but each had his private retirement, where he studied and performed his devotions by himself. If any person had killed another by chance, he applied to these sages for absolution, and submitted to whatever penances they enjoined. They observed an extraordinary frugality, and lived only upon the fruits of the earth. Lucan ascribes to these gymnosophists several new discoveries in astronomy.

The Indian gymnosophists dwelt in the woods, where they lived upon the wild products of the earth, and never drank wine, nor married. Some of them practised physic, and travelled from one place to another: these were particularly famous for their remedies against barrenness. Some of them, likewise, pretended to practise magic, and to foretell future events.

GYMNOSPERMIA, in botany, from γυμνος, naked, and σπερμα, seed; the first order in Linnæus's class of didynamia. It comprehends those plants of that class which have naked seeds. The seeds are constantly four in number, except in one genus, viz. phryma, which is monospermous.

GYMNOTUS, *gymnote*, a genus of fishes belonging to the apodes. The generic character is, head with lateral opercula; tentacula two on the upper lip; eyes covered by the common skin; gill-membrane five-rayed; body compressed, without dorsal fin (in most species), but carinated by a fin beneath. The most remarkable species, are:

1. The gymnotus electricus, a native of the warmer regions of Africa and America, where it inhabits the larger rivers, and is particularly found in those of Surinam. In Africa it is said chiefly to occur in the branches of the river Senegal. It is a fish of a disagreeable appearance; bearing a general resemblance to a large eel, though somewhat thicker in proportion, and of a much darker colour, being commonly of an uniform blackish-brown. It is usually seen of the length of three or four feet, but is said to arrive at a far larger size, specimens occasionally oc-

curring of 6, 7, or even ten feet in length. It was first made known to the philosophers of Europe about the year 1671, when its wonderful properties were announced to the French academy by Mons. Richer, one of the gentlemen sent out by the academy to conduct some mathematical observations in Cayenne. This account however seems to have been received with a degree of cautious scepticism by the major part of European naturalists; and it was not till towards the middle of the last century that a full and general conviction appears to have taken place; the observations of Mons. Condamine, Mr. Ingram, Mr. Gravesend, and others, then conspiring to prove that the power of this animal consists in a species of real electricity, being conducted by similar conducting substances, and intercepted by others of an opposite nature. Thus, on touching the fish with the fingers, the same sensation is perceived as on touching a charged phial; being sometimes felt as far as the elbows; and if touched by both hands, an electric shock is conveyed through the breast in the usual manner. Fermin, in particular, who, during his residence in Surinam, had frequent opportunities of examining the animal, demonstrated by experiment that 14 slaves, holding each other by the hands, received the shock at the same instant; the first touching the fish with a stick, and the last dipping his hand into the water in which it was kept. The experiments of Dr. Bancroft were equally satisfactory (see ELECTRICITY). It is by this extraordinary faculty that the gymnotus supports its existence: the smaller fishes and other animals which happened to approach it, being instantly stupified, and thus falling an easy prey to the electrical tyrant. So powerful is the shock which this fish, in its native waters, is capable of exerting, that it is said to deprive almost entirely of sense and motion those who are exposed to its approach, and is therefore much dreaded by those who bathe in the rivers which it inhabits. See Pl. LXVII. Nat. Hist. fig. 218.

It has been affirmed that the gymnotus electricus, even for some time after its death, cannot be touched without feeling its electric shock. This is by no means incredible, when we consider the effect of the galvanic pile, so well known to modern philosophers.

2. Gymnotus carapo. The head of the carapo is of a compressed form, and the upper jaw projects beyond the lower: the tongue is short, thick, broad, and furnished like the jaws with a great many small sharp-pointed teeth: the eyes are very small, and the front of the head is marked, as in the preceding species, by a number of small round pores: the body gradually decreases towards the tail, which is extremely slender, and terminates in a point. The colour of the whole animal is brown, marked by a few irregular spots or patches of a deeper cast: the scales are small, and the lateral line straight. This fish is a native of the American seas, and is said to be most frequent on the coast of Surinam. It is supposed to live chiefly on small fishes, sea insects, &c. Whether it possesses any electric power, like the former species, may be doubted; yet the structure of the lower part of the body seems to imply somewhat of a similar contrivance of nature. The usual length of the carapo is from 1 to 2 feet; but it is sometimes found of the length of three feet, and of the weight of more than ten pounds. It is considered as an esculent fish by the South Americans.

3. Gymnotus rostratus, or rostrated gymnote. In its general aspect this species is much allied to the carapo, but is readily distinguished by the peculiar form of the head, which terminates in a narrow, slightly compressed, tubular snout, the jaws appearing in a manner connate: the colour of the body is pale reddish-brown, variegated with differently sized spots of a darker colour, and which are much smaller, as well as more numerous, on the fin than on the other parts: the pectoral fins are round, and rather small for the size of the animal: the eyes are very small: the scales, if any, are so small as to be not distinctly visible on a general view. This species is a native of Surinam, and seems to have been first described and figured by Seba.

4. Gymnotus acus, or needle gymnote. This species is described by Brunnich, in his history of the fish of Marseilles. It is whitish, with reddish and brown spots, which cause a kind of clouded variegation on the back, while a blueish tinge prevails towards the under parts: on the back is a kind of projection, which may be rather considered as a rudiment of a fin than a perfect one: the whole animal is of a long, compressed, and attenuated form, and the mouth is destitute of tentacula. This is the only European species of gymnote yet discovered, and is a native of the Mediterranean sea. Biside these there are 11 other species.

GYNANDRIA, from γυνή, a woman, and ἀνήρ, a man, the name of the 20th class in Linnæus's sexual system, consisting of plants with hermaphrodite flowers, in which the stamina are placed upon the style, or, to speak more properly, upon a pillar-shaped receptacle resembling a style, which rises in the middle of the flower, and bears both the stamina and pointal; that is, both the supposed organs of generation, (see BOTANY). The flowers of this class, says Linnæus, have a monstrous appearance; arising, as he imagines, from the singular and unusual situation of the parts of fructification.

GYNOPOGON, a genus of the pentandria monogynia class and order. The calyx is half five-cleft; corolla five-parted; stigma globular, two lobed; berry pedicelled, sub-globular; seed cartilaginous. There are three species, herbs of the South Seas, of no note.

GYPSUM. See LIME, *sulphat of.*

What formerly was called gypsum, or selenite, is now known to be a sulphat of lime. It is also distinguished by the name of plaister stone, &c.

GYRINUS, or glimmerchaffer, a genus of insects of the coleoptera order. The generic character is, antennæ clavated, stiff, shorter than the head: eyes (apparently) four, two above and two below.

The genus gyrinus is furnished with extremely short, stiff antennæ, appearing to consist of an undivided piece or joint; but, if accurately inspected by means of a magnifier, they will be found to be composed of very numerous close set joints: the eyes are so placed as to appear double on each side the head, viz. one above, and the other below the base of the antennæ.

The most remarkable European species is the gyrinus natator, a small insect, about a quarter of an inch in length, of an oval shape, with somewhat sharpened extremities, and of a black or grey-black colour, with so lucid a surface as to shine like a piece of looking-glass in the full sunshine. It is an inhabitant of the waters, and

is chiefly found in rivulets, being generally seen in great multitudes, and in very brisk motion. It is difficult to catch, diving with astonishing celerity when disturbed; the hinder legs being very broad, finely webbed with minute hairs, and most curiously formed for exercising the office of fins or oars. The larva is of a highly singular aspect, having a very lengthened body, furnished, exclusive of six legs on the foreparts, with a great many lateral appendages or processes down the body; those towards the extremity considerably exceeding the rest. In its motions it is extremely agile, swimming in a kind of serpentine manner, and preying on the smaller and weaker water-insects, minute worms, &c.; the head is armed with a pair of forceps, pierced on each side the tip with a small foramen, through which it sucks the juices of the animals on which it preys; the colour of this larva is a very pale or whitish brown, with a high degree of transparency, which renders it a very curious object for the microscope: its length, when full-grown, is about three quarters of an inch. When the time of its changes arrives, it forms for itself a small oval cell or case on a leaf of sedge, or other convenient water-plant, and after casting its skin, becomes a chrysalis: this change usually takes place in the month of August, and the complete insect emerges in that of September.

When these animals are congregated together in great multitudes on the surface of the water, which frequently happens in hot weather, they have been observed to diffuse a strong or disagreeable smell to a considerable distance. Like other water-beetles they fly only by night. They deposit their eggs, which are very small, white, and of a somewhat cylindric form, on the stems of water-plants; they hatch in the space of about eight days, and immediately begin to swim about with much briskness in quest of prey. There are only 2 species.

GYRFALCON. See Falco.

GYPSIES. See Egyptians.

GYPSOPHILA, a genus of the digynia order, in the decandria class of plants, and in the natural method ranking under the 22d order, caryophillei. The calyx is monophyllous, campanulated, and angulated; the petals are five in number, ovate, and sessile; the capsule globose and unilocular. There are 12 species, herbs of Europe.

H.

H, the eighth letter in our alphabet; used as a numeral, denotes 200; and with a dash over it, $\overline{H}$, 200,000.

As an abbreviation, H was used by the ancients to denote *homo*, *hæres*, *hora*, &c. Thus H. B. stood for hæres bonorum; and H. S. corruptly for L. L. S. a sesterce; and H. A. for Hadrianus.

HABDALA, a ceremony of the Jews, observed on the sabbath in the evening; intended to signify that the sabbath is over, and if from that moment divided from the day of labour which follows. For this reason the ceremony is called habdala, which signifies distinction.

HABEAS CORPUS. This writ formed part of the ancient common law, but was much more restrained in its operation and effects; for the judges arrogated to themselves the power of granting or denying it; and the gaolers did not pay a proper attention to it, often putting the sufferer to the expense of an alias and pluries habeas corpus before they obeyed. These inconveniences produced the famous statute 31 Car. II. c. 2.

This great bulwark of English liberty, which may fairly be put upon a level with the celebrated Magna Charta, was occasioned by the unjust oppression of an insignificant individual in the reign of Charles the Second. The statute enacts,

1st. That the lord chancellor, or any of the judges in vacation, on complaint or written request of any person committed for any crime (except felony, or treason, or as accessary, or suspected of being accessary before the fact, to any petty treason, or felony, or charged in execution by legal process), upon seeing a copy of the warrant, or affidavit that copy is denied, shall award a habeas corpus for such prisoner, returnable immediately before himself, or any other of the judges (unless the party has suffered two terms to elapse before applying to the court for his liberation), and shall discharge the party, if bailable, on his giving proper security to appear.

2dly. That the writ shall be indorsed, as granted in pursuance to this act, and signed by the person awarding it.

3dly. That the writ shall be returned, and the prisoner brought up in a limited time, according to the distance, never exceeding 20 days.

4thly. That officers and keepers not making due returns, or not delivering to the party or his agent, within six hours after demand, a copy of the warrant of commitment, or shifting the custody of a prisoner without proper authority (as mentioned in the act), shall forfeit 100*l.* for the first offence, and 200*l.* for the second, to the sufferer, and be disabled from holding such office.

5thly. That any one detaining a person once delivered by habeas corpus for the same offence, shall forfeit 500*l.*

6thly. That every person committed for treason or felony shall, if he desires it, the first week of the next term, or the first day of the next session of oyer and terminer, be indicted in that term or session, or else admitted to bail, unless the witnesses for the crown cannot be produced at that time, and if acquitted, or not indicted, and tried in the second term or session, shall be discharged; but no person after the commencement of assizes for the county where he is detained, shall be removed by habeas corpus till they are ended.

7thly. That a prisoner can obtain his habeas corpus out of the chancery and exchequer, as well as out of the king's bench and common pleas; and if the chancellor and judges shall refuse the same on sight of the warrant or oath that it is denied, shall forfeit severally 500*l.* to the party grieved.

8thly. That this writ of habeas corpus shall run into

the counties palatine, and all other privileged places, and the islands of Guernsey and Jersey.

9thly. That no inhabitants of England (unless at their desire, or having committed some capital offence in the place to which they are sent), shall be sent prisoners to Ireland, Scotland, Guernsey, and Jersey, or any places beyond the seas, within or without his majesty's dominions, on pain that the person committing, and his advisers and abettors, shall forfeit to the injured party a sum not less than 500*l.* to be recovered with treble costs, shall be disabled from holding any office, shall incur the penalties of præmunire, and be incapable of the king's pardon.

The writs in use under this act are various. Many kinds are used for removing prisoners from one court to another. Such are the *habeas corpus ad respondendum,* when a man has cause of action against one who is confined by process of an inferior court, in order to remove the prisoner, and charge him with this new action in the court above. *Ad satisfaciendum* is when judgment has, in an action, been given against a prisoner, and the plaintiff brings him up to a superior court to charge him with process of execution. Also the writs *ad prosequendum, testificandum, deliberandum,* which issue when it is necessary to remove a prisoner, in order to prosecute, or bear testimony, or to be tried in the proper jurisdiction, wherein the fact was committed. And, lastly, he common writ *ad faciendum et recipiendum,* which issues out of any of the courts above, when a person is sued in some inferior jurisdiction, and desires to remove the action into the superior court, commanding the inferior judges to produce the body of the defendant, with the day and cause of his detainer, to do and receive what the king's court shall determine. This writ is grantable of common right, without moving the court, and supersedes all inferior proceedings. But to prevent the surreptitious discharge of prisoners, the statute 1 and 2 P. and M. c. 13, enacts, that no habeas corpus shall issue to remove any prisoner out of goal, unless signed by some judge of the court out of which it is awarded. And by a statute of the present reign it is enacted, that no cause under the value of 10*l.* shall be removed into a superior court, unless the defendant, on removing the same, gives security for payment of debt and costs.

But the writ which forms so great a part of the liberty of the subject in all manner of illegal confinement, is the *habeas corpus ad subjiciendum,* commanding the person detaining a prisoner to produce him, with the day and cause of his detension, to submit to whatever the judge or court awarding such writ shall determine. This is a high prerogative writ, and therefore, by the common law, issuing out of the court of king's bench, not only in term time, but vacation, by a fiat from any of the judges, and running into all the king's dominions. And a man has now the benefit of the common law writ, either in the king's bench or common pleas, as he chooses; and in both those courts it is necessary to apply for it by motion, as it does not issue of course, without showing some reason for the granting it. But if good grounds be shown that the party is imprisoned without just cause, it becomes a writ of common right, and must not be denied, even though a man is detained by the highest authority.

This celebrated act has been subject to temporary suspensions, by authority of parliament, in times of riot or rebellion; and the late minister subjected himself to considerable unpopularity by that measure during the last war.

HABENDUM, in a deed, is to determine what estate or interest is granted by the deed, the certainty thereof, for what time, and to what use. It sometimes qualifies the estate, so that the general implication thereof, which, by construction of law, passes in the premises, may by the habendum be controlled: in which case the habendum may lessen or enlarge the estate, but not totally contradict or be repugnant to it. As if a grant is to one and the heirs of his body, to leave to him and his heirs for ever, here he has an estate tail by the grant, and by the habendum he has a fee simple expectant thereon. But if it had been in the premises to him and his heirs, to have for life, the habendum would be utterly void; for an estate of inheritance is vested in him before the habendum comes, and shall not afterwards be taken away, or divested by it. 2 Black. 298.

The habendum cannot pass any thing that is not expressly mentioned, or contained by implication in the premises of the deed; because the premises being part of the deed by which the thing is granted, and consequently that makes the gift; it follows that the habendum, which only limits the certainty and extent of the estate in the thing given, cannot increase or multiply the gift, because it would be absurd to say that the grantee shall hold a thing which was never given him. 2 Roll. Abr. 65. See DEED.

HABERDASHER, in commerce, a seller of hats, or of small wares.

The master and wardens of the company of haberdashers in London, calling to their assistance one of the company of cappers, and another of the hat-makers, and mayors, &c. of towns, may search the wares of all hatters that work hats with foreign wool, and have not been apprentices to the trade, or who dye them with any thing but copperas and galls, or woad and madder; in which case they are liable to penalties, by stat. 8 Eliz. c. 7, and 5 Geo. II. c. 22.

HABERE FACIAS SEISINAM, a writ of execution directed to the sheriff, commanding him to give to the plaintiff possession of a freehold: if it is a chattel interest, and not a freehold, then the writ is entitled habere facias possessionem. 3 Black. 412.

In the execution of these writs, the sheriff, if needful, may take with him the power of the county, and may justify breaking open doors, if the possession is not quietly delivered; but if it is peaceably delivered up, the yielding of a twig, a turf, or the ring of a door, in the name of seisin, is sufficient. Id.

HABERE FACIAS VISUM, a writ that lies in divers cases in real actions, as in dower, formedon, &c. where view is required to be taken of the lands or tenements in question.

HABERGEON, a small coat of mail, or only sleeves and gorget of mail, formed of little iron rings or meshes linked into each other.

HADDOCK. See GADUS.

HÆMANTHUS, the *blood flower,* a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the ninth order, spathaceæ. The involucrum is hexaphyllous and multiflo-

rous; the corolla sexpartite, superior; the berry trilocular. There are eight species, of which the principal are:

1. The coccineus, with plain tongue-shaped leaves, rises about a foot high, with a stalk supporting a cluster of bright-red tubulous flowers. It has a large bulbous root, from which in the autumn come out two broad flat leaves of a fleshy consistence, shaped like a tongue, which turn backward on each side, and spread on the ground, so that they have a strange appearance all the winter. In the spring these decay; so that from May to the beginning of August they are destitute of leaves. The flowers are produced in the autumn just before the leaves come out.

2. The carinatus, with keel-shaped leaves, has a taller stalk and paler flowers than the former; its leaves are not flat, but hollowed like the keel of a boat.

3. The puniceus, with large spear-shaped waved leaves, grows about a foot high, and has flowers of a yellowish-red colour. These are succeeded by berries, which are of a beautiful red colour when ripe. All these plants are natives of the Cape of Good Hope.

HÆMATITES, or *blood stone*, a hard mineral substance, red, black, or purple, but the powder of which is always red. It is found in masses sometimes spherical, semi spherical, pyramidal, or cellular, that is, like a honeycomb. It contains a large quantity of iron. Forty pounds of that metal have been extracted from a quintal of stone; but the iron is of such a bad quality, that this ore is not commonly smelted. The great hardness of hæmatites renders it fit for burnishing and polishing metals. The specific gravity from 47 to 50. See Plate LXVII. Nat. Hist. fig. 220.

HÆMATOPUS, the *sea-pye*, in ornithology, a genus belonging to the order of grallæ. The beak is compressed, with an equal wedge-shaped point; the nostrils are linear; and the feet have three toes without nails. There is but one species, viz. the ostralegus, or oyster-catcher, a native of Europe and America. See Plate LXVII. N. H. fig. 219. It feeds upon shell-fish near the sea-shore, particularly oysters and limpets. On observing an oyster which gapes wide enough for the insertion of its bill, it thrusts it in, and takes out the inhabitant: it will also force the limpets from their adhesion to the rocks with sufficient ease. Occasionally it feeds on marine insects and worms. With us these birds are often seen in considerable flocks in winter: in the summer they are met with only in pairs, though chiefly in the neighbourhood of the sea or salt rivers.

HÆMATOXYLUM, *logwood*, or *Campeachy wood*, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The calyx is quinquepartite; the petals five; the capsule lanceolated, unilocular, and bivalved; the valves navicular, or keeled like a boat. Of this genus there is only one species, viz. the campeachianum, which grows naturally in the bay of Campeachy at Honduras, and other parts of the Spanish West Indies, where it rises from 16 to 24 feet high. The stems are generally crooked, and very deformed, and seldom thicker than a man's thigh. The branches, which come out on each side, are crooked, irregular, and armed with strong thorns, and winged leaves, composed of three pair of obscure lobes indented at the top The flowers come in a racemus from the wings of the leaves, standing erect, and are of a pale-yellowish colour, with a purple empalement. They are succeeded by flat oblong pods, each containing two or three kidney-seeds.

Logwood is used in great quantities for dyeing purple, but especially black colours. All the colours, however, which can be prepared from it, are of a fading nature, and cannot by any art be made equally durable with those prepared from some other materials. Of all the colours prepared from logwood, the black is the most durable. Doctor Lewis recommends it as an ingredient in making ink. "In dyeing cloth (says he), vitriol and galls, in whatever proportions they are used, produce only browns of different shades: I have often been surprised that with these capital materials of the black dye I never oould obtain any true blackness in white cloth, and attributed the failure to some unheeded mismanagement in the process, till I found it to be a known fact among the dyers. Logwood is the material which adds blackness to the vitriol and gall brown; and this black dye, though not of the most durable kind, is the most common. On blue cloth a good black may be dyed by vitriol and galls alone; but even here an addition of logwood contributes not a little to improve the colour." Mr. Delaval, however, in his Essay on Colours, informs us, that with an infusion of galls and iron-filings, he not only made an exceeding black and durable ink, but also linen cloth of a very deep black.

HÆMOPTOSIS, in medicine, a spitting of blood. See MEDICINE.

HÆMORRHAGE, in medicine, a flux of blood from any part of the body. See MEDICINE.

HÆMORRHOIDS, or PILES. See MEDICINE.

HÆRUCA, in entomology, a genus of the order of vermes intestina. The body is round, the fore part two-necked, and surrounded with a single row of prickles. The H. muris is grey-white and wrinkled: it inhabits the intestines of the mouse, and is distinguished from the echinorhynchus, in wanting the retractile proboscis.

HAIL, in natural history, a meteor generally defined frozen rain, but differing from it in that the hailstones are not formed of single pieces of ice, but of many little spherules agglutinated together. Neither are these spherules all of the same consistence; some of them being hard and solid like perfect ice; others soft, and mostly like snow hardened by a severe frost. Sometimes the hailstone has a kind of core of this soft matter; but more frequently the core is solid and hard, while the outside is formed of a softer matter. Hailstones assume various figures, being sometimes round, at other times pyramidal, crenated, angular, thin, and flat, and sometimes stellated, with six radii like the small crystals of snow. See METEOROLOGY.

Natural historians furnish us with various accounts of surprising showers of hail, in which the hailstones were of extraordinary magnitude. Mezeray, speaking of the war of Louis XII. in Italy, in the year 1510, relates, that there was for some time a horrible darkness, thicker than that of night; after which the clouds broke into thunder and lightning, and there fell a shower of hailstones, or rather (as he calls them) pebble-stones, which destroyed all the fish, birds, and beasts, of the country. It was attended with a strong smell of sulphur; and the

stones were of a blueish colour, some of them weighing a hundred pounds. Hist. de France, tom. ii. p. 339.

At Lisle, in Flanders, in 1686, fell hail-stones of a very large size; some of which contained in the middle a dark-brown matter, which, thrown on the fire, gave a very great report. Phil. Trans. No. 203.

Dr. Halley and others also relate, that in Cheshire, Lancashire, &c. April 29, 1697, a thick black cloud coming from Carnarvonshire, disposed the vapours to congeal in such a manner, that for about the breadth of two miles, which was the limit of the cloud, in its progress, for the space of 60 miles, it did inconceivable damage; not only killing all sorts of fowls and other small animals, but splitting trees, knocking down horses and men, and even ploughing up the earth; so that the hailstones buried themselves under ground an inch or an inch and a half deep. The hailstones, many of which weighed five ounces, and some half a pound, and being five or six inches about, were of various figures; some round, others half-round; some smooth, others embossed and crenated: the icy substance of them was very transparent and hard, but there was a snowy kernel in the middle of them.

In Hertfordshire, May 4, the same year, after a severe storm of thunder and lightning, a shower of hail succeeded the former: some persons were killed by it, and their bodies were beaten all black and blue; vast oaks were split, and fields of rye cut down as with a scythe. The stones measured from 10 to 13 or 14 inches about. Their figures were various, some oval, others picked, and some flat. Philosoph. Trans. No. 229.

Methods have lately been proposed, in England and France, to draw off the lightning, and dissipate hailstorm. Monthly Magazine, July 1806.

HAIR. See Physiology.

Hair and feathers cover different parts of animals, and are obviously intended by nature to protect them from the cold. For this their softness and pliability, and the slowness with which they conduct heat, render them peculiarly proper.

1. Hair is usually distinguished into various kinds, according to its size and appearances. The strongest and stiffest of all is called bristle: of this kind is the hair on the back of hogs. When remarkably fine, soft, and pliable, it is called wool; and the finest of all is known by the name of down. But all these varieties resemble one another very closely in their composition.

Hair appears to be a kind of tube covered with a cuticle. Its surface is not smooth, but either covered with scales, or consisting of imbricated cones. Hence the roughness of its feel, and the disposition which it has to entangle itself, which has given origin to the process of felting and fulling. It is constantly increasing in length, being protruded from the roots, and seems at first to be soft or nearly gelatinous. From the experiments which have been made on hair by Achard and Hatchett, it follows that it contains gelatine, to which it owes its suppleness and toughness. This substance may be separated by boiling the hair in water. When thus treated it becomes much more brittle than before. Indeed if the process is continued long enough, the hair crumbles to pieces between the fingers. The portion insoluble in water possesses the properties of coagulated albumen.

Mr. Hatchett has concluded, from his experiments, that the hair which loses its curl in moist weather, and which is the softest and most flexible, is that which yields its gelatine most easily; whereas strong and elastic hair yields it with the greatest difficulty, and in the smallest proportion. This conclusion has been confirmed by a very considerable hair-merchant in London, who assured him that the first kind of hair was much more injured by boiling than the second.

The rapidity with which hair burns, and the fusion which it undergoes in that case, shows us, however, that hair does not altogether correspond with coajulated albumen in its nature, but approaches towards the oils. When distilled, 1152 parts of hair yielded Bertholett the following products:

90	carbonat of ammonia
179	water smelling of burnt hair
288	oil
271	gases
324	coal
1152.	

The oil was of a brown colour, solid unless exposed to a heat equal to 73°, very soluble in alcohol, burnt with great brilliancy, and with scintillations like hair. The charcoal was difficult to incinerate, and was attracted by the magnet; of course it contained iron. From the experiments of Fourcroy and Vauquelin, we learn that horsehair, when burnt, leaves a residuum of 0.12, which is mostly phosphat of lime.

The alkalies dissolve hair at a boiling-heat, and form with it an animal soap; but lime appears to have but little action on it. When muriatic acid is poured into the solution of hair in potass, a quantity of sulphureted hydrogen gas is disengaged, and a black substance, doubtless charcoal, precipitates. Hence it follows that it contains sulphur. Accordingly, if a bit of silver is put into the solution, it instantly assumes a black colour.

Sulphuric acid dissolves hair by the assistance of heat, some charcoal is deposited, and carbonic acid gas separates. Nitric acid tinges it yellow, and dissolves it when assisted by heat; while a fat matter separates, and oxalic acid is formed. Bertholett obtained from wool more than half its weight of oxalic acid. Muriatic acid dissolves it readily; but the solution does not become black, and has much the appearance of a solution of glue in the same acid. Oxymuriatic acid whitens hair, and destroys its strength. When the hair is plunged into the acid in the state of gas, it is very soon converted into a pulp.

2. Feathers seem to possess very nearly the same properties with hair. Mr. Hatchett has ascertained that the quill is composed chiefly of coagulated albumen. Though feathers were boiled for a long time in water, Mr. Hatchett could obtain no traces of gelatine.

Hair's breadth, a measure of length, being the 48th part of an inch.

HALCYON. See Alcedo.

HALE. See Haul.

HALESIA, a genus of the monogynia order, in the dodecandria class of plants; and in the natural method ranking under the 18th order, bicornes. The calyx is quadridentated, superior; the corolla quadrifid; the nut quadrangular and dispermous. There are two species, herbaceous plants of North America.

HALF-MOON, in fortification, an outwork composed of two faces, forming a saliant angle, whose gorge is in form of a crescent, or half-moon; whence the name. See FORTIFICATION.

HALF-SEAL, that used in the court of chancery for sealing commissions to delegates, upon any appeal, in ecclesiastical or marine causes.

HALIOTIS, the ear-shell, a genus of insects belonging to the order of vermes testacea. This is an animal of the snail kind, with an open shell resembling an ear. There are nineteen species, distinguished by the figure of their shells.

HALLERIA, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 40th order, personatæ. The calyx is trifid; the corolla quadrifid; the filaments longer than the corolla; the berry inferior and bilocular (the fruit not yet fully described). There is one species, a shrub of the Cape.

HALO, in physiology, a meteor in the form of a luminous ring or circle, of various colours, appearing round the bodies of the sun, moon, or stars. See OPTICS.

HAMELLIA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is quinquefid; the berry quinquelocular, inferior, polyspermous. There are four species, trees of the West Indies.

HAMMER, a well-known tool used by mechanics, consisting of an iron head, fixed crosswise upon a handle of wood.

There are several sorts of hammers used by blacksmiths; as, 1. The hand-hammer, which is of such weight that it may be wielded or governed with one hand at the anvil. 2. The up-hand sledge, used with both hands, and seldom lifted above the head. 3. The about-sledge, which is the largest hammer of all, and held by both hands at the farthest end of the handle, and being swung at arm's-length over the head, is made to fall upon the work with as heavy a blow as possible. There is also another hammer used by smiths, called a rivetting-hammer, which is the smallest of all, and is seldom used at the forge, unless upon small work.

HAMSOKEN, is used in Scotland for the crime of him that violently, and contrary to the king's peace, assaults a man in his own house, which is punishable equally with ravishing a woman.

HANAPER *office*, in the court of chancery, is that out of which issue all original writs that pass under the great seal, and all commissions of charitable uses, sewers, bankrupts, ideocy, lunacy, and such-like. These writs, relating to the business of the subject, and the returns to them, were originally kept in a hamper, in hanaperio; the other writs, relating to matters wherein the crown is immediately or mediately concerned, were preserved in a little sack or bag, in parva baga; and thence has arisen the distinction of the hanaper office and petty-bag office: both of which belong to the common law court in chancery. 3 Black. 48.

HANCES, in a ship, are falls or descents of the fife rails, which are placed from the stern down to the gangways.

HAND. See ANATOMY.

HAND-BARROW, a wheelbarrow which is of great use in fortification, for carrying earth from one place to another, and in a siege, for carrying bombs or cannon-balls along the trenches.

HAND-BREADTH, a measure of three inches.

HAND-CUFFS, an instrument formed of two circular pieces of iron, each fixed on a hinge at the ends of a very short iron bar, which being locked over the wrists of a malefactor, prevents his using his hands

HAND-GRENADES. See GRENADES.

HARBINGER, an officer of the king's household, having four yeomen under him, who ride a days journey before the court, when it travels, to provide lodgings.

HARDENING, the giving a greater degree of hardness to bodies than they had before. See the article HARDNESS.

There are several ways for hardening iron and steel, as by hammering them, quenching them, when hot, in cold water, case-hardening, &c. See IRON.

HARDNESS, in bodies, a property directly opposite to fluidity; by which they resist the impression of any other substance, sometimes in an extreme degree. As fluidity has been found to consist in the motion of the particles of a body upon one another in consequence of a certain action of the universal fluid or elementary fire among them; we must conclude that hardness consists in the absence of this action, or a deficiency of what is called latent heat. This is confirmed by observing that there is an intermediate state betwixt hardness and fluidity, in which bodies will yield to a certain force, though they still make a considerable resistance. This is principally observed in the metals, and is the foundation of their ductility. It appears, indeed, that this last property, as well as fluidity, is entirely dependant on a certain quantity of caloric absorbed, or otherwise acting within the substance itself; for all the metals are rendered hard by hammering, and soft by being put again into the fire and kept there for some time. The former operation renders them hot as well as hard; probably, as Dr. Black observes, because the particles of metal are thus forced nearer one another, and those of fire squeezed out from among them. By keeping them for some time in the fire, that element insinuates itself again among the particles, and arranges them in the same manner as before, so that the ductility returns. By a second hammering this property is again destroyed, returning on a repetition of the heating, or annealing as it is called; and so on, as often as we please.

Hardness appears to diminish the cohesion of bodies in some degree, though their fragility does not by any means keep pace with their hardness. Thus, glass is very hard and very brittle; but flint, though still harder than glass, is much less brittle. Among the metals, however, these two properties seem to be more connected, though even here the connection is by no means complete. Steel, the hardest of all the metals, is indeed the most brittle; but lead, the softest, is not the most ductile. Neither is hardness connected with the specific gravity of bodies; for a diamond, the hardest substance in nature, is little more than half the weight of the lightest metal. As little is it connected with the coldness, electrical properties, or any other quality with which we are acquainted: so that though the principle above laid down may be accepted as a general foundation for our inquiries, a great num-

ber of particulars remain yet to be discovered before we can offer any satisfactory explanation.

All bodies become harder by cold; but this is not the only means of their doing so, for some become hard by heat as well as cold.

Mr. Quist and others have constructed tables of the hardness of different substances. The method pursued in constructing these tables was by observing the order in which they were able to cut or make any impression upon one another. The following table, extracted from M. Magellen's edition of Cronstedt's Mineralogy was taken from Dr. Quist Bergman, and Mr. Kirvan. The first column shows the hardness, and the second the specific gravity.

	H.	S.G.
Diamond from Ormus	20	3,7
Pink diamond	19	3,4
Bluish diamond	19	3,3
Yellowish diamond	19	3,3
Cubic diamond	18	3,2
Ruby	17	4,2
Pale ruby from Brazil	16	3,5
Ruby spinell	13	3,4
Deep-blue sapphire	16	3,8
Ditto paler	17	3,8
Topaz	15	4,2
Whitish ditto	14	3,5
Bohemian ditto	11	2,8
Emerald	12	2,8
Garnet	12	4,4
Agate	12	2,6
Onyx	12	2,6
Sardonyx	12	2,6
Occid. amethyst	11	2,7
Crystal	11	2,6
Carnelian	11	2,7
Green jasper	11	2,7
Reddish-yellow ditto	9	2,6
Schoerl	10	3,6
Tourmaline	10	3,0
Quartz	10	2,7
Opal	10	2,6
Chrysolite	10	3,7
Zeolite	8	2,1
Fluor	7	3,5
Calcareous spar	6	2,7
Gypsum	5	2,3
Chalk	3	2,7

HARE. See LEPUS.

HARIOT. See HERIOT.

HARMATTAN. The harmattan is a very singular wind, which blows periodically from the interior parts of Africa towards the Atlantic Ocean. The season in which it prevails is during the months of December, January, and February; it comes on indiscriminately at any hour of the day, at any time of the tide, or at any period of the moon, and continues sometimes only a day or two, sometimes five or six days, and it has been known to last fifteen and sixteen days. There are generally three or four returns of it every season. It blows with a moderate force, but not quite so strong as the sea-breeze.

A fog or haze is one of the peculiarities which always accompany the harmattan. The English, French, and Portuguese forts at Whydah, are not quite a quarter of a mile asunder, yet are frequently quite invisible to each other; the sun, concealed the greatest part of the day, appears only about a few hours at noon, and then of a mild red, exciting no painful sensation on the eye. The particles which constitute this fog are deposited on the leaves of trees, on the skins of the negroes, &c. and make them appear whitish.

Extreme dryness makes another extraordinary property of this wind; no dew falls during its continuance; vegetables are withered, and the grass becomes dry like hay. The natives take this opportunity to clear the land, by setting fire to the trees and plants while in that dry and exhausted state. The dryness is so extreme, that the covers of books, even closely shut up in a trunk, are bent as if exposed to the fire. Household furniture is much damaged; the pannels of wainscots split, and fineered work flies to pieces. The joints of a well-laid floor of seasoned wood open sufficiently to admit the breadth of a finger between them; but becomes as close as before on the ceasing of the harmattan. The human body does not escape the parching effects of this wind; the eyes, nostrils, lips, and palate, are rendered dry and uneasy; the lips and nose become sore, and though the air is cool, there is a troublesome sensation of pricking heat on the skin. If the harmattan continues four or five days, the scarf-skin peels off, first from the hands and face, and afterwards from the rest of the body.

Though this wind is so fatal to vegetable life, and occasions these troublesome effects to the human species, it is nevertheless highly conducive to health; it stops the progress of epidemics, and relieves the patients labouring under fluxes and intermittent fevers. Infection is not easy at that time to be communicated, even by inoculation. It is also remarkable for the cure of ulcers and cutaneous diseases. Econ. of Nat. b. 5.

HARMONICA. This word, when originally appropriated by Dr. Franklin to that peculiar form or mode of musical glasses, which he himself, after a number of happy experiments, had constituted, was written Armonica. It is derived from the Greek word ἁρμονια. The radical word is αρειν, to suit or fit one thing to another. Relations or aptitudes of sound, in particular, were understood by it; and in this view, Dr. Franklin could not have selected a name more expressive of its nature and genius for the instrument which we are now to describe; as, perhaps, no musical tone can possibly be finer, nor consequently susceptible of juster concords, than those which it produces.

"Mr. Puckridge, a gentleman from Ireland, was," says Dr. Franklin, "the first who thought of playing tunes formed of these tones. He collected a number of glasses of different sizes; fixed them near each other on a table; and tuned them, by putting into them water, more or less as each note required. The tones were brought out by pressing his fingers round their brims. He was unfortunately burnt here, with his instrument, in a fire which consumed the house that he lived in. Mr. E. Deleval, a most ingenious member of the royal society, made one in imitation of it, with a better choice and form of glasses, which was the first I saw or heard. Being charmed with the sweetness of its tones, and the music

be produced from it, I wished to see the glasses disposed in a more convenient form, and brought together in a narrower compass, so as to admit of a greater number of tones, and all within reach of hand to a person sitting before the instrument; which I accomplished, after various intermediate trials, and less commodious forms, both of glasses and construction, in the following manner:

"The glasses are blown as nearly as possible in the form of hemispheres, having each an open neck or socket in the middle. The thickness of the glass near the brim is about the tenth of an inch, or hardly so much, but thicker as it comes nearer the neck; which in the largest glasses is about an inch deep, and an inch and a half wide within; these dimensions lessening as the glasses themselves diminish in size, except that the neck of the smallest ought to be shorter than half an inch. The largest glass is nine inches diameter, and the smallest three inches. Between these there are 23 different sizes, differing from each other a quarter of an inch in diameter. To make a single instrument there should be at least six glasses blown of each size; and out of this number one may probably pick 37 glasses (which are sufficient for three octaves with all the semitones) that will be each either the note one wants, or a little sharper than that note, and all fitting so well into each other as to taper pretty regularly from the highest to the smallest. It is true that there are not 37 sizes; but it often happens that two of the same size differ a note or half a note in tone, by reason of a difference in thickness, and these may be placed one in the other without sensibly hurting the regularity of the taper form.

"The glasses being chosen, and every one marked with a diamond the note you intend it for, they are to be tuned by diminishing the thickness of those that are too sharp. This is done by grinding them round from the neck towards the brim, the breadth of one or two inches as may be required; often trying the glass by a well-tuned harpsichord, comparing the note drawn from the glass by your finger with the note you want, as sounded by that string of the harpsichord. When you come near the matter, be careful to wipe the glass clean and dry before each trial, because the tone is something flatter when the glass is wet than it will be when dry; and grinding a very little between each trial, you will thereby tone to great exactness. The more care is necessary in this, because if you go below your required tone, there is no sharpening it again but by grinding somewhat off the brim, which will afterwards require polishing, and thus increase the trouble.

"The glasses being thus toned, you are to be provided with a case for them, and a spindle on which they are to be fixed. My case is about three feet long, eleven inches every way wide within at the biggest end, and five inches at the smallest end; for it tapers all the way, to adapt it better to the conical figure of the set of glasses. This case opens in the middle of its height, and the upper part turns up by hinges fixed behind. The spindle is of hard iron, lies horizontally from end to end of the box within, exactly in the middle, and is made to turn on brass gudgeons at each end. It is round, an inch diameter at the thickest end, and tapering to a quarter of an inch at the smallest. A square shank comes from its thickest end through the box, on which shank a wheel is fixed by a screw. This wheel serves as a fly to make the motion equable, when the spindle, with the glasses, is turned by the foot like a spinning-wheel. My wheel is of mahogany, 18 inches diameter, and pretty thick, so as to conceal near its circumference about 25lb. of lead. An ivory pin is fixed in the face of this wheel, about four inches from the axis. Over the neck of this pin is put the loop of the string that comes up from the moveable step to give it motion. The case stands on a neat frame with four legs.

"To fix the glasses on the spindle, a cork is first to be fitted in each neck pretty tight, and projecting a little without the neck, that the neck of one may not touch the inside of another when put together, for that would make a jarring. These corks are to be perforated with holes of different diameters, so as to suit that part of the spindle on which they are to be fixed. When a glass is put on, by holding it stiffly between both hands, while another turns the spindle, it may be gradually brought to its place. But care must be taken that the hole be not too small, lest in forcing it up, the neck should split; nor too large, lest the glass, not being firmly fixed, should turn or move on the spindle, so as to touch or jar against its neighbouring glass. The glasses thus are placed one in another; the largest on the biggest end of the spindle, which is to the left hand: the neck of this glass is towards the wheel; and the next goes into it in the same position, only about an inch of its brim appearing beyond the brim of the first; thus proceeding, every glass when fixed shows about an inch of its brim (or three quarters of an inch, or half an inch, as they grow smaller) beyond the brim of the glass that contains it; and it is from these exposed parts of each glass that the tone is drawn, by laying a finger on one of them as the spindle and glasses turn round.

"My largest glass is G a little below the reach of a common voice, and my highest G, including three complete octaves. To distinguish the glasses more readily by the eye, I have painted the apparent parts of the glasses within side, every semistone white, and the other notes of the octave with the seven prismatic colours; viz. C, red; D, orange; E, yellow; F, green; G, blue; A, indigo; B, purple; and C, red again; so that the glasses of the same colour (the white excepted) are always octaves to each other.

"This instrument is played upon by sitting before the middle of the set of glasses, as before the keys of a harpsichord, turning them with the foot, and wetting them now and then with a sponge and clean water. The fingers should be first a little soaked in water, and quite free from all greasiness; a little fine chalk upon them is sometimes useful, to make them catch the glasses and bring out the tone more readily. Both hands are used, by which means different parts are played together. Observe, that the tones are best drawn out when the glasses turn *from* the ends of the fingers, not when they turn *to* them.

"The advantages of this instrument are, that its tones are incomparably sweet beyond those of any other; that they may be swelled and softened at pleasure by stronger or weaker pressures of the finger, and continued to any length; and that the instrument being once well tuned, never again wants tuning."

"Analogous to these sounds," says a writer in the Annual Register, "are those produced by bells: in those last, besides the tones produced by their elliptical vibrations, there are a set of tones which may be brought by gently rubbing their edges, and in which the whole instrument does not appear to vibrate in all its parts as before.

"Take, for instance, a bell finely polished at the edges; or, what will perhaps be more convenient, a drinking-glass: let the edges be as free from any thing oily as possible; then, by moistening the finger in water (I have found alum-water to be best), and rubbing it circularly round the edge of the glass, you will at length bring out the tone referred to.

"This note is possessed of infinite sweetness; it has all the excellences of the tone of a bell, without its defects. It is loud, has a sufficient body, is capable of being swelled and continued at pleasure; and besides, has naturally that vibratory softening which musicians endeavour to imitate by mixing with the note to be played a quarter-tone from below.

"To vary these tones, nothing more is required than to procure several bells or glasses of different tones, tuned as nearly as possible, which may be done by thinning the edges of either: or, for immediate satisfaction, the glasses may be tuned by pouring in water; the more water is poured in, the graver the tone will be.

"Let us suppose then a double octave of those glasses, thus tuned, to be procured. Any common tune may be executed by the fingers rubbing upon each glass successively; and this I have frequently done without the least difficulty, only choosing those tunes which are slow and easy. Here then are numbers of delicate tones, with which musicians have been till very lately unacquainted; and the only defect is, that they cannot be made to follow each other with that celerity and ease which is requisite for melody. In order to remedy this, I took a large drinking-glass, and by means of a wheel and gut, as in the electrical machine, made it to turn upon its axis with a moderately quick but equable motion; then moistening the finger as before, nothing more was required than merely to touch the glass at the edge, without any other motion, in order to bring out the tone.

"Instead of one glass only turning in this manner, if the whole number of glasses were so fixed as to keep continually turning by means of a wheel, it follows, that upon every touch of the finger a note would be expressed; and thus, by touching several glasses at once, a harmony of notes might be produced, as in a harpsichord.

"As I write rather to excite than satisfy the curious, I shall not pretend to direct the various ways this number of glasses may be contrived to turn; it may be sufficient to say, that if the glasses are placed in the segment of a circle, and then a strap, as in a cutler's wheel, is supposed to go round them all, the whole number will by this means be made to turn by a wheel.

"Instead of the finger, I have applied moistened leather to the edge of the glass, in order to bring out the tone: but, for want of a proper elasticity, this did not succeed. I tried cork, and this answered every purpose of the finger; but made the tone much louder than the finger could do. Instead, therefore, of the finger, if a number of corks were so contrived as to fall with a proper degree of pressure on the edge of the glass, by means of keys like the jacks of an organ, it is evident, that in such a case a new and tolerably perfect instrument would be produced; not so loud indeed as some, but infinitely more melodious than any."

HARMONICAL Arithmetic, that part of arithmetic which considers musical intervals, expressed by numbers, in order to our finding their mutual relations, compositions, and resolutions.

Harmonical Proportion. See Proportion.

Harmonical Series, a series of many numbers in continual harmonical proportion. Thus if there are four or more numbers, of which every three immediate terms are harmonical, the whole will make an harmonical series: such is 30: 20: 15: 12: 10. Or, if every four terms immediately next each other are harmonical, it is also a continual harmonical series, but of another species, as 3, 4, 6, 9, 18, 36, &c.

HARMONY, in music (from the Greek), the agreement or consonance of two or more united sounds. Harmony is either natural or artificial. Natural harmony, properly so called, consist of the harmonic triad, or common chord. Artificial harmony is a mixture of concords and discords, bearing relation to the harmonic triad of the fundamental note. The word harmony being originally a proper name, it is not easy to determine the exact sense in which it was used by the Greeks; but from the treatises they have left us on the subject, we have great reason to conclude that they limited its signification to that agreeable succession of sounds which we call air, or melody. The moderns, however, do not dignify a mere succession of single sounds with the appellation of harmony: for the formation of harmony they require an union of melodies, a succession of combined sounds composed of consonant intervals, and moving according to the stated laws of modulation. But as the laws of harmony were not established into a code but by very slow degrees, its principles for a long time consisted of no other than almost arbitrary rules, founded, indeed, on the approbation of the ear, but unsanctioned by that science which accounts for effects rationally, and deduces its conclusions from minute, profound, and satisfactory investigation. At length, however, writers arose, to whose patience, talents, and learning, the present age is indebted for a complete system of harmony and modulation, and to whose labours we only have to resort, to be informed on every point requisite both to its theory and practice.

Harmony, Figured. Figured harmony is that in which, for the purpose of melody, one or more of the parts of a composition move during the continuance of a chord, through certain notes which do not form any of the constituent parts of that chord. These intermediate notes not being reckoned in the harmony, considerable judgment and skill are necessary so to dispose them that while the ear is gratified with their succession, it may not be offended at their dissonance with respect to the harmonic notes. See Sounds.

HARP, a stringed instrument, consisting of a triangular frame, and the chords of which are distended in parallel directions from the upper part to one of its sides. Its scale extends through the common compass, and the strings are tuned by semitonic intervals. It stands erect,

and when used, is placed at the feet of the performer, who produces its tones by the action of the thumb and fingers of both hands on the strings. That the harp is among the most ancient of musical instruments, the frequent mention of it in scripture, and the splendid account transmitted to us of the Theban harp, both as to the beauty of its decorations and extent of scale, are sufficient evidences. The Irish and Welsh practised the harp long before the gammut of Guido was invented, and it is, indeed, their national instrument. In England also it was early introduced to general use, and the most ancient poems were sung to it on Sundays and all public festivals.

HARPING-IRON, or Harpoon, a large spear or javelin, made of forged iron, and five or six feet long; it is fastened to a line, and used in the whale-fishery.

HARPINGS, in a ship, properly denote her breadth at the bow. Some also give the same name to the ends of the bends that are fastened into the stern.

HARPOON-Gun, a sort of fire-arm for discharging harpoons at whales, and thereby killing them more expeditiously than when harpoons are thrown by the hand. See Transactions of the Society for the Encouragement of Arts, &c. 1786, 1789, &c.

HARPSICHORD, a stringed instrument, consisting of a case formed of mahogany or walnut-tree wood, and containing the belly or sounding-board, over which the wires are distended, supported by bridges. In the front the keys are disposed, the long ones of which are the naturals, and the short ones the sharps and flats. These keys being pressed by the fingers, their inclosed extremities raise little upright oblong slips of wood called jacks, furnished with crow-quill plectrums, which strike the wires. The great advantage of the harpsichord beyond most other stringed instruments, consists in its capacity of sounding many notes at once, and forming those combinations, and performing those evolutions of harmony, which a single instrument cannot command. This instrument, called by the Italians clave cymbala, by the French clavecin, and in Latin grave cymbalum, is an improvement upon the clarichord, which was borrowed from the harp, and has for more than a century been in the highest esteem, and in the most general use, both public and private, throughout Europe; but since the invention of that fine instrument the grand piano-forte, its practice has considerably declined.

HARQUEBUSS, a piece of fire-arms, of the length of a musquet, usually cocked with a wheel. It carried a ball that weighed one ounce seven eighths.

HARRIER. See Canis.

HARROW. See Husbandry.

HART. See Cervus.

HARTOGIA, a genus of the pentandria order, in the monœcia class of plants; and is the natural method ranking under the 48th order, aggregatæ. The male calyx is pentaphyllous, the petals five; the female calyx triphyllous, with five petals, and five barren and five castrated stamina. There are three capsules; and the seeds are arillated, or inclossed in a deciduous case. There is one species, a tree of the Cape.

HARTSHORN, in chemistry. See Ammonia.

Hart's Horns, in pharmacy, the whole horns of the common male deer, as separated from the head, without farther preparation. See Horns.

HASSELQUISTA, a genus of the class and order pentandria digynia. The cal. is radiated, in the disk male. Seeds in the circumference double, in the disk solitary. There are two species, herbs of Egypt.

HAT, a covering for the head, worn by the men in most parts of Europe and America. Those most in esteem are made of the pure hair of the castor or beaver; for they are also made of the hairs or wool of diver other animals, and that by much the same process.

Hats are made either of wool, or hair of various animals, particularly of the castor, hare, rabbit, camel, &c. The process is much the same in all; for which reason we shall content ourselves with instancing that of the beaver. The skin of this animal is covered with two kinds of hair; the one long, stiff, glossy, and rather thin-set; this is what renders the skin or fur of so much value: the other is short, thick, and soft, which alone is used in hats. To tear off one of these kinds of hair, and cut the other, the hatters, or rather the women employed for that purpose, make use of two knives, a large one like a shoemaker's knife for the long hair, and a smaller, not unlike a vine-knife, wherewith they shave or scrape off the shorter hair.

When the hair is off, they mix the stuff; to one-third of dry castor putting two-thirds of old coat, *i. e.* of hair which has been worn some time by the savages, and card the whole with cards, like those used in the woollen-manufactory, only finer; this done, they weigh it, and take more or less according to the size or thickness of the hat intended. The stuff is now laid on the hurdle, which is a square table, parallel to the horizon, having longitudinal chinks cut through it; on this hurdle, with an instrument called a bow, much like that of a violin, but larger, whose string is worked with a little bow-stick, and thus made to play on the furs, they fly and mix together, the dust and filth at the same time passing through the chinks. This they reckon one of the most difficult operations in the whole, on account of the justness required in the hand to make the stuff fall precisely together, and that it may be every where of the same thickness. In lieu of a bow, some hatters make use of a sieve or searce of hair, through which they pass the stuff.

After this manner they form gores, or two capades, of an oval form, ending in an acute angle at top; and with what stuff remains, they supply and strengthen them in places where they happen to be slenderer than ordinary; though it is to be remembered, that they designedly make them thicker in the brim, near the crown, than toward the circumference, or in the crown itself.

The capades thus furnished, they go on to harden them into closer and more consistent flakes by pressing down a hardening skin or leather thereon; this done, they are carried to the bason, which is a sort of bench with an iron plate fitted in it, and a little fire underneath; upon which laying one of the hardened capades, sprinkled over with water, and a sort of mould being applied, the heat of the fire, with the water and pressing, embody the matter into a slight hairy sort of stuff or felt; after which, turning up the edges all round the mould, they lay it by, and thus proceed to the other: this finished, the next two are joined together, so as to meet in an angle at the top, and only form one conical cap, after the manner of a manican hippocratis, or jelly-bag.

The hat thus basoned, they remove it to a large kind of receiver or trough, resembling a mill-hopper, going sloping or narrowing down from the edge or rim to the bottom, which is a copper kettle filled with water and grounds, kept hot for that purpose. On the descent or sloping side, called the plank, the basoned hat, being first dipped in the kettle, is laid; and here they proceed to work it, by rolling and unrolling it again and again, one part after another, first with the hand, and then with a little wooden roller, taking care to dip it from time to time, till at length, by thus fulling and thickening it four or five hours, it is reduced to the extent or dimensions of the hat intended.

The hat thus wrought, they proceed to give it the proper form, which is done by laying the conical cap on a wooden block, of the intended size of the crown of the hat, and then tying it round with a packthread: after which, with a piece of iron or copper bent for that purpose, and called a stamper, they gradually beat or drive it down all round, till it has reached the bottom of the block, and thus is the crown formed; what remains at bottom below the string being the brim.

The hat being set to dry, they proceed to singe it, by holding it over a flare of straw or the like; then it is pounced, or rubbed over with pumice, to take off the coarser knap; then rubbed over afresh with seal-skin to lay the knap a little finer; and lastly, carded with a fine card to raise the fine cotton, with which the hat is afterwards to appear.

Things thus far advanced, the hat is thus sent, upon its block, and tied about with a packthread as before, to be dyed. The dye being completed, the hat is returned to the hatter, who proceeds to dry it, by hanging it in the top or roof of the stove or oven, at the bottom of which is a charcoal fire; when dry, it is to be stiffened, which is done with melted glue or gum senegal, applied thereon by first smearing it, and beating it over with a brush, and then rubbing it with the hand. The next thing is to steam it on the steaming-bason, which is a little hearth or fire-place. When steamed sufficiently, and dried, they put it again on the block, and brush and iron it on a table or bench for the purpose, called the stall-board; this they perform with a sort of irons like those commonly used in ironing linen, and heated like them, which being rubbed over and over each part of the hat, with the assistance of the brush, smooths and gives it a gloss, which is the last operation; nothing now remains but to clip the edges even with scissars, and sew a lining to the crown. For dyeing of hats, see DYEING.

A patent was granted in January, 1782, to Mr. Robert Golding, of London, hat-dyer, for his method of dyeing, staining, and colouring, beaver hats green, or any other colour. The inventor directs the nap of the hat to be raised by means of a card, on the side intended to be dyed, and then boiled in alum argol. A thin paste should be made of flour, or clay, which is spread over every part that is not to be dyed, and then closed; or the hat may be previously pasted, and instead of being boiled, it should only be simmered in the same liquor. As soon as the paste is spread, plates of copper or other metal, shaped like a common funnel, are fixed over the paste, to prevent the dye from penetrating through. In this state the hat is immersed in the dye, till the colour is sufficiently fixed, when it is taken out, opened, and cleansed from the paste: but if any colouring particles have penetrated through the felt, they may be removed by rubbing them with a small quantity of spirit of salt, aquafortis, &c. The compounds employed in dyeing, are fustic, turmeric, ebony, saffron, alum, argol, indigo, and vitriol, with urine, or pearlash, at the option of the dyer; all which is used together, or separately, according to the colour required.

Mr. Dunnage, in 1794, obtained a patent for waterproof hats, in imitation of beaver. The articles he employs are similar to those commonly used for the making of hats, with which he mixes Bergam, Piedmont, or organzine silk. These are dressed and worked in a peculiar manner; though we understand that hats thus prepared become heavy and oppressive to the wearer, while they acquire an ugly colour. The same manufacturer procured another patent in November, 1798, for a method of ventilating the crowns of hats. This invention consists in separating the top from the sides of the crown, so that the tip, or top crown, may be either raised or let down at pleasure, in order to admit the external air, or to exclude it from circulating in the crown of the hat. The whole contrivance is effected by means of springs, sliders, sockets, grooves, loops, and cases, which are connected with the top and side-crown: thus the admission or exclusion of atmospheric air in front, behind, or on either side, may be regulated accordingly. See Repertory, vol. iv. and x.

Another patent was granted for the same thing to Messrs. Walker and Alphey, in the year 1801.

Hats are also made for women's wear, of chips, straw, or cane, by platting, and sewing the plats together; beginning with the centre of the crown, and working round till the whole is finished. Hats for the same purpose are also woven, and made of horse hair, silk, &c. There are few manufactures in which so little capital is wanted, or the knowledge of the art so soon acquired, as in that of straw-platting. One guinea is quite sufficient for the purchase of the machines and materials for employing one hundred persons for several months.

The straw is cut at the joints; and the outer covering being removed, it is sorted of equal sizes, and made up into bundles of eight or ten inches in length, and a foot in circumference. They are then to be dipped in water, and shaken a little so as not to retain too much moisture; and then the bundles are to be placed on their edges, in a box which is sufficiently close to prevent the evaporation of smoke. In the middle of the box is an earthen dish containing brimstone broke in small pieces: this is set on fire, and the box covered over and kept in the open air several hours.

It will be the business of one person to split and select the straws for fifty others who are braiders. The splitting is done by a small machine made principally of wood. The straws, when split, are termed splints, of which each worker has a certain quantity: on one end is wrapped a linen cloth, and they are held under the arm, and drawn out as wanted.

Platters should be taught to use their second fingers and thumbs, instead of the fore-fingers, which are often required to assist in turning the splints, and very much

facilitate the platting; and they should be cautioned against wetting the splints too much. Each platter should have a small linen work-bag, and a piece of pasteboard to roll the plat round. After five yards have been worked up, it should be wound about a piece of board half a yard wide, fastened at the top with yarn, and kept there several days to form it in a proper shape. Four of these parcels, or a score, is the measurement by which the plat is sold.

HATCHEL, HACKLE, or HITCHEL, a tool with which flax and hemp are combed into fine hairs. It consists of long iron pins, or teeth, regularly set in a piece of board.

There are several sorts of hatchels, each finer than the other, with which flax and hemp are prepared for spinning.

HATCHES, in a ship, a kind of trap-doors between the main-mast and fore-mast, through which all goods of bulk are let down into the hold.

HATCHES also denote flood-gates set in a river, &c. to stop the current of the water; particularly certain dams or mounds made of rubbish, clay, or earth, to prevent the water that issues from the stream-works and tin-washes in Cornwal, from running into the fresh rivers.

HATCHING, the maturating fecundated eggs, whether by the incubation and warmth of the parent bird, or by artificial heat, so as to produce young chickens alive.

The art of hatching chickens by means of ovens has long been practised in Egypt; but it is there only known to the inhabitants of a single village named Berme, and to those who live at a small distance from it. Towards the beginning of autumn they scatter themselves all over the country, where each person among them is ready to undertake the management of an oven, each of which is of a different size, but in general they are capable of containing from forty to fourscore thousand eggs. The number of these ovens placed up and down the country is about three hundred and eighty-six, and they usually keep them working for about six months: as therefore each brood takes up in an oven, as under a hen, only twenty-one days, it is easy in every one of them to hatch eight different broods of chickens. Every Bermean is under the obligation of delivering to the person who intrusts him with an oven, only two-thirds of as many chickens as there have been eggs put under his care; and he is a gainer by this bargain, as more than two-thirds of the eggs usually produce chickens. In order to make a calculation of the number of chickens yearly so hatched in Egypt, it has been supposed that only two-thirds of the eggs are hatched, and that each brood consists of at least thirty thousand chickens; and thus it would appear that the ovens of Egypt give life yearly to at least ninety-two millions six hundred and forty thousand of these animals.

This useful and advantageous method of hatching eggs has been employed in France, by the ingenious Mr. Reaumur, who, by a number of experiments, reduced the art to certain principles. He found by experience that the heat necessary for this purpose is nearly the same with that marked 32 on his thermometer, or that marked 96 on Fahrenheit's. This degree of heat is nearly that of the skin of the hen, and what is remarkable, of the skin of all other domestic fowls, and probably of all other kinds of birds. The degree of heat which brings about the developement of the cygnet, the gosling, and the turkey-pout, is the same as that which fits for hatching the canary-songster, and, in all probability, the smallest humming-bird: the difference is only in the time during which this heat ought to be communicated to the eggs of different birds: it will bring the canary-bird to perfection in eleven or twelve days, while the turkey-pout will require twenty-seven or twenty-eight.

Mr. Reaumur invented a sort of low boxes, without bottoms, and lined with furs. These, which he calls artificial parents, not only shelter the chickens from the injuries of the air, but afford a kindly warmth, so that they presently take the benefit of their shelter as readily as they would have done under the wings of a hen. After hatching, it will be necessary to keep the chickens for some time in a room artfully heated, and furnished with these boxes; but afterwards they may be safely exposed to the air in the court-yard, in which it may not be amiss to place one of these artificial parents to shelter them if there would be occasion for it.

As to the manner of feeding the young brood, they are generally a whole day after being hatched before they take any food at all; and then a few crumbs of bread may be given them for a day or two, after which they will begin to pick up insects and grass for themselves. But to save the trouble of attending them, capons may be taught to watch them in the same manner as hens do. Mr. Reaumur assures us that he has seen above two hundred chickens at once, all led about and defended only by three or four such capons. Nay, cocks may be taught to perform the same office, which they, as well as the capons, will continue to do all their lives after.

HATCHING, or *Haching*, in designing, &c. the making of lines with a pen, pencil, or graver, or the like; and the intersecting or going across those lines with others drawn a contrary way, is called counter-hatching. The depths and shadows of draughts are usually formed by hatching.

HATTOCK, a shock of corn containing twelve sheaves: others make it only three sheaves laid together.

HAUL, or HALE, an expression peculiar to seamen, implying to pull a single rope, without the assistance of blocks or other such mechanical powers. To haul the wind, is to direct the ship's course nearer to that point of the compass from which the wind arises.

HAUTBOY, a musical instrument of the wind-kind, shaped much like the flute, only that it spreads and widens towards the bottom, and is sounded through a reed. The treble is two feet long; the tenor goes a fifth lower, when blown open: it has only eight holes; but the bass, which is five feet long, has eleven.

HAWK. See FALCO.

HAWKERS and PEDLARS, are such dealers or itinerary petty chapmen as travel to different fairs or towns with goods or wares, and are placed under the control of commissioners, by whom they are licensed for that purpose pursuant to stat. 8 and 9 W. III. c. 25. and 29 Geo. III. c. 26. Traders in linen and woollen manufactories sending their goods to markets and fairs, and selling them by wholesale; manufacturers selling their own manufactures, and makers and sellers of English bone-

lace going from house to house, &c. are excepted out of the acts, and not to be taken as hawkers.

HAWKING. See FALCONRY.

HAWSER, in the sea-language, a large rope, or a kind of small cable, serving for various uses aboard a ship, as to fasten the main and fore shrouds, to warp a ship as she lies at anchor, and wind her up by a capstern, &c. The hawser of a man of war may serve for a cable to the sheet-anchor of a small ship.

HAWSES, in a ship, are two large holes under the bow, through which the cables run when she lies at anchor. Thus the Hawse-pieces are the large pieces of timber in which these holes are made. Hawse-bags, are bags of canvas made tapering, and stuffed full of oakum; which are generally allowed small ships, to prevent the sea from washing in at these holes: and hawse-plugs are plugs to stop the hawses, to prevent the water from washing into the manger.

There are also some terms in the sea-language that have an immediate relation to the hawses. Thus a bold hawse, is when the holes are high above the water. Fresh the hawse, or veer out more cable, is used when part of the cable that lies in the hawse is fretted or chafed, and it is ordered that more cable may be veered out, so that another part of it may rest in the hawses. Fresh the hawse, that is, lay new pieces upon the cable in the hawses, to preserve it from fretting. Burning in the hawse, is when the cables endure a violent stress. Clearing the hawses, is disentangling two cables that come through different hawses. To ride hawse-full, is when in stress of weather the ship falls with her head deep in the sea, so that the water runs in at the hawses.

HAY, any kind of grass, cut and dried, for the food of cattle. See HUSBANDRY.

HAZARD: a game on dice, without tables, is very properly so called, since it speedily makes a man, or undoes him.

It is played with only two dice; and as many may play it as can stand round the largest round table.

Two things are chiefly to be observed, viz. main and chance; the latter belonging to the caster, and the former, or main, to the other gamesters. There can be no main thrown above nine, nor under five; so that five, six, seven, eight, and nine, are the only mains flung at hazard. Chances and nicks are from four to ten: thus four is a chance to nine, five to eight, six to seven, seven to six, eight to five; and nine and ten a chance to five, six, seven, and eight: in short, four, five, six, seven, eight, nine, and ten are chances to any main, if any of these nick it not. Now nicks are either when the chance is the same with the main, as five and five, or the like; or six and twelve, seven and eleven, eight and twelve. Here observe, that twelve is out to nine, seven, and five; eleven is out to nine, eight, six, and five; and ames-ace and deuce-ace are out to all mains whatever.

But to illustrate this game by a few examples: Suppose the main to be seven, and the caster throws five, which is his chance; he then throws again, and if five turn up, he wins all the money set him; but if seven is thrown, he must pay as much money as there is on the board: again, if seven is the main, and the caster throws eleven, or a nick, he sweeps away all the money on the table; but if he throws a chance, as in the first case, he must throw again: lastly, if seven is the main, and the caster throws ames-ace, deuce-ace, or twelve, he is out; but if he throws from four to ten, he has a chance; though they are accounted the worst chances on the dice, as seven is reputed the best and easiest main to be flung. Four and five are bad throws (the former of which being called by the tribe of nickers little dick-fisher), as having only two chances, viz. trey-ace and two deuces, or trey-deuce and quartre-ace: whereas seven has three chances, viz. cinque-deuce, sice-ace, and quartre-trey. Nine and ten are in the like condition with four and five, having only two chances. Six and eight have indeed the same number of chances with seven, viz. three; but experienced gamesters nevertheless prefer the seven, by reason of the difficulty to throw the doublets, two quarters, or two treys. It is also the opinion of most, that at the first throw the caster has the worst of it. On the whole, hazard is certainly one of the most bewitching and ruinous games played on the dice. Happy, therefore, the man who either never heard of it, or who has resolution enough to leave it off in time.

HAZEL. See CORYLUS.

HEAD. See ANATOMY.

HEAD. See ARCHITECTURE.

HEAD, in heraldry. The heads of men, beasts, or birds, are very frequent in armoury; and borne either full-faced, looking forward, or side-faced in profile, when only one half of the face appears, which differences ought to be mentioned in blazoning, to avoid mistakes; as a head, or heads fronting; or a head, or heads side-faced, or in profile: thus, vert, a chevron gules, between three turks'-heads couped side-faced proper, is borne by the name of Smith. And again, or, a cross gules, between four blackmoors' heads, couped at the shoulders proper, is borne by the name Juxon. As the head is the principal part of the body, so it is of course the noblest bearing.

Among medalists, the different heads on ancient coins, are distinguished by the different dresses. See MEDAL.

In the imperial medals, where the head is quite bare, it is usually a sign the person was not an emperor, but one of the children of an emperor, the presumptive heir of the empire. The heads which are covered, are either covered with a diadem, or a crown, or a simple cork, or a veil, with some other foreign covering, whereof the diadem is the most ancient. The heads of deities are distinguished by some special symbol.

HEAD-ACHE. See MEDICINE.

HEADBORROW, or HEADBOROUGH, the chief of the frankpledge, and he that had the principal government of them within his own pledge. And as he was called headborrow, so was he called burrowhead, bursholder, thirdborrow, tithingham, chief-pledge, or borrow-elder, according to the diversity of terms in several places. The same officer is now occasionally called a constable. The headborough was the chief of the ten pledges: the other nine were called hardboroughs, or inferior pledges.

HEAD-LINES, in a ship, those ropes of all sails which are next to the yards, and by which the sails are made fast to the yards.

HEAD-SEA, is when a great wave or billow of the sea comes right ahead of the ship, as she is in her course.

HEAD-SAILS, in a ship, those which belong to the fore-

mast and boltsprit: for it is by these that the head of the ship is governed, and made to fall off and keep out of the wind; and these in quarter-winds are the chief drawing sails.

Head *of a ship*, or other vessel, is the prow, or that part which goes foremost.

Dragon's Head, in astronomy, &c. is the ascending node of the moon, or other planet. See Node.

HEARING, the sense whereby we perceive sounds. See Anatomy, Physiology, and Sounds.

HEARSAY, is generally not to be admitted as evidence; for no evidence is to be allowed but what is upon oath; for if the first speech was without oath, another oath that there was such speech, makes it no more than a bare speaking, and so of no value in a court of justice; and besides, the adverse party has no opportunity of a cross-examination; and if the witness is living, what he has been heard to say is not the best evidence that the nature of the thing will admit. But in some cases hearsay evidence is allowed to be admissible; as to prove who was a man's grandfather, when he married, what children he had, and the like; of which it is not reasonable to presume that there is better evidence. So in questions of prescription, it is allowed to give hearsay evidence, in order to prove general reputation; as where the issue was of a right to a way over the plaintiff's close, the defendant was admitted to give evidence of a conversation between persons not interested, then dead, wherein the right to the way was agreed. Theory of Evid. III. See Evidence.

HEARSE. See Hind.

HEART. See Anatomy.

HEAT, in physiology. See Caloric.

Heat, *Animal.* See Respiration.

Heat, in geography, the diversity of the heat of climates and seasons arising chiefly from the different angles under which the sun's rays strike upon the surface of the earth. Dr. Halley gives a mathematical computation of the effect of the sun under the different seasons and climates. Let it, however, be considered, that the different degrees of heat and cold in different places depend in a very great measure upon the accidents of situation, with regard to mountains and valleys, and the soil. The first greatly helps to chill the air by the winds which come over them, and which blow in eddies through the levels beyond; and mountains, sometimes turning a concave side to the sun, have the effects of a burning mirror upon the subject plain; and the like effect is sometimes had from the convex parts of clouds, either by refraction, or reflection. As to soils, a stony, sandy, or chalky earth, it is known, reflects most of the sun's rays into the air again, and retains but few, by which means a considerable accession of heat is derived to the air; as, on the contrary, black loose soils absorb most of the rays, and return few into the air, so that the ground is much the hotter.

The following table of the heat of different climates is computed for every tenth degree of latitude, to the equinoctial and tropical sun; by which an estimate may be made of the intermediate degrees.

Lat.	Sun in ♈ ♎	Sun in ♋	Sun in ♑
0	20000	18341	18341
10	19696	20290	15854
20	18797	21737	13166
30	17321	22651	10124
40	15321	23048	6944
50	12855	22991	3798
60	10000	22773	1075
70	6840	23543	000
80	3473	24673	000
90	0000	25055	000

Hence are deducible the following corollaries. 1. That the equinoctial heat, when the sun becomes vertical, is as twice the square of the radius, which may be proposed as a standard to compare with in all other cases. 2. That under the equinoctial, the heat is as the sine of the sun's declination. 3. That in the frigid zones, where the sun sets not, the heat is as the circumference of a circle into the sine of the altitude at 6; and consequently that in the same latitude these aggregates of warmth are as the sine of the sun's declination; and at the same declination of the sun, they are as the sines of the latitudes into the signs of the declination. 4. That the equinoctial day's heat is every where as the cosine of the latitude. 5. In all places where the sun sets, the difference between the summer and winter heats, when the declinations are contrary, is equal to a circle into the sine of the altitude at 6 in the summer parallel; and consequently these differences are as the sine of the latitude into or multiplied by the sines of declination. 6. From the foregoing table, it appears that the tropical sun under the equinoctial, has of all others the least force. Under the pole, it is greater than any other day's heat whatever; being to that of the equinoctial as 5 to 4.

HEATH. See Erica.

HEBENSTRETIA, a genus of the angiospermia order, in the didynamia class of plants; and in the natural method ranking under the 48th order, aggregatæ. The calyx is emarginated, and divided below; the corolla unilabiate; the lip rising upwards, and quadrifid; the capsule dispermous; the stamina inserted into the margin of the limb of the corolla. There are six species, herbs of the Cape.

HECATOMBÆON, in ancient chronology, the first month of the Athenian year, consisting of thirty days, and answering to the latter part of our June and beginning of July.

HECTIC, or Hectic Fever. See Medicine.

HEDERA, Ivy, a genus of the monogynia order, in the pentandria class of plants; and in the natural method giving name to the 46th order, hederaceæ. There are five oblong petals; the berry is pentaspermous, girt by the calyx There are six species; the most remarkable are: 1. The helix, or common ivy, which grows naturally in many parts of Britain; and, where it meets with any support, will rise to a great height, sending out roots on every side, which strike into the joints o walls or the bark of trees. If there is no support, they trail on the ground, and take root all their length, so that they closely cover the surface, and are difficult to eradicate. While these stalks are fixed to any support,

or trail upon the ground, they are slender and flexible; but when they have reached to the top of their support, they shorten and become woody, forming themselves into large bushy heads; and their leaves are larger, more of an oval shape, and not divided into lobes like the lower leaves, so that it has a quite different appearance. There are two varieties of this species; one with silver-striped leaves, the other with yellowish leaves on the tops of the branches; and these are sometimes admitted into gardens. 2. The quinquefolia, or Virginia creeper, is a native of all the northern parts of America. It was first brought to Europe from Canada; and has been long cultivated in the British gardens, chiefly to plant against walls or buildings to cover them: which these plants will do in a short time; for they will shoot almost twenty feet in one year, and will mount up to the top of the highest buildings; but as the leaves fall off in autumn, the plants make but an indifferent appearance in winter, and therefore are proper only for such situations as will not admit of better plants; for this will thrive in the midst of cities, and is not injured by the smoke or the closeness of the air.

The roots of the ivy are used by leather-cutters to whet their knives upon. Apricots and peaches covered with ivy during the month of February, have been observed to bear fruit plentifully. The leaves have a nauseous taste; Haller says, they are given to children in Germany, as a specific for the atrophy. The common people of England apply them to issues; and an ointment made from them is in great esteem among the Highlanders of Scotland as a ready cure for burns. The berries have a little acidity. In warm climates, a resinous juice exudes from the stalks, which is said to be a powerful resolvent, and an excellent ingredient in plasters and ointments. Horse and sheep eat the plant; goats and cows refuse it.

HEDGE-Breakers, by 43 Eliz. c. 7. shall pay such damages as a justice of the peace shall think fit; and on nonpayment shall be whipped. And by 15 Car. II. c. 6. the constable may apprehend a person suspected, and by warrant of a justice, may search his houses and other places; and if any hedge-wood shall be found, and he shall not give a good account how he came by the same, he shall be adjudged the stealer thereof.

HEDGES. See Husbandry.

HEDWIGEN, a genus of the octandria monogynia class and order. The cal. is four-toothed; the cor. four-cleft; style none; caps. tricoccous; seed a nut. There is one species, a tree of St. Domingo.

HEDYCARYA, a genus of the icosandria order, in the diœcia class of plants. The calyx of the male is cleft in eight or ten parts; there is no corolla, nor are there any filaments; the antheræ are in the bottom of the calyx, four-furrowed, and bearded at top. The calyx and corolla of the female are as in the male; the germs pedicellated; the nuts pedicellated and monospermous. There is one species, a tree of Guiana.

HEDYCREA, a genus of the class and order pentandria monogynia. The cal. is one-leafed, hemispherical, five-toothed: cor. none: drupe oval, one-celled: nect. ovate, covered with fibres, one-celled; shell hard. There is one species, a tree of Guiana.

HEDYOSMUM, a genus of the class and order monœcia polyandria. The male is an ament with anthers; no cor. perianth. or filaments. The female has cal. three-toothed; cor. none; style one, three-cornered; berry three-cornered, one-seeded. There are two species, shrubs of Jamaica.

HEDYOTIS, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 47th order, stellatæ. The corolla is monopetalous and funnel-shaped; the capsule is bilocular, polyspermous, inferior. There are eight species, herbs of Ceylon, &c.

HEDYPNOIS, a genus of the class and order syngenesia polygamia æqualis. The cal. is calycled, with short scales; seeds crowned with the calycle; recept. naked, hollow-dotted.

HEDYSARUM, a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceæ. The carina of the corolla is transversely obtuse; the seed-vessel a legumen with monospermous joints. There are 90 species of this plant, of which the most remarkable are: 1. The gyrans, or sensitive hedysarum, a native of the East Indies, where it is called burrum chundalli. It arrives at the height of four feet, and in autumn produces bunches of yellow flowers. The root is annual or biennial. It is a trifolious plant, and the lateral leaves are smaller than those at the end, and all day long they are in constant motion without any external impulse. They move up and down, and circularly. This last motion is performed by the twisting of the footstalks; and while the one leaf is rising, its associate is generally descending. The motion downwards is quicker and more irregular than the motion upwards, which is steady and uniform. These motions are observable for the space of 24 hours in the leaves of a branch which is lopped off from the shrub, if it is kept in water. If from any obstacle the motion is retarded, upon the removal of that obstacle it is resumed with a greater degree of velocity. 2. The coronarium, or common biennial French honeysuckle, has large deeply-striking biennial roots; upright, hollow, smooth, very branchy stalks, three or four feet high, with pinnated leaves; and from between the leaves proceed long spikes of beautiful red flowers, succeeded by jointed seed-pods. The first species, being a native of hot climates, requires the common culture of tender exotics; the second is easily raised from seed in any of the common borders, and is very ornamental.

HEEL. See Anatomy.

Heel, in the sea-language. If a ship leans on one side, whether she is aground or afloat, then it is said she heels astarboard, or aport; or that she heels offwards, or to the shore; that is, inclines more to one side than to another.

HEGIRA, in chronology, a celebrated epocha among the Mahometans. The event which gave rise to this epocha was the flight of Mahomet from Mecca, with his new proselytes, to avoid the persecution of the Koraischites; who, being then most powerful in the city, could not bear that Mahomet should abolish idolatry, and establish his new religion. This flight happened in the fourteenth year after Mahomet had commenced prophet: he retired to Medina, which he made the place of his residence.

HEIGHT, in geometry, is a perpendicular let fall from the vertex, or top, of any right-lined figure, upon the base or side subtending it. It is likewise the perpendicular height of any object above the horizon; and is found several ways; by two staffs, a plain mirror with the quadrant, theodolite, or some graduated instrument, &c.

The measuring of heights or distances is of two kinds: when the place or object is accessible, as when you can approach to its bottom; or inaccessible, when it cannot be approached.

PROB. I. *To measure an accessible height* AB, *by means of two staffs.* See plate LXXII. Miscel. fig. 111.

Let there be placed perpendicularly in the ground, a longer staff DE, likewise a shorter one FG, so that the observer may see A, the top of the height to be measured, over the ends D, F, of the two staffs; let FH and DC, parallel to the horizon, meet DE and AB in H and C; then the triangles FHD, DCA, shall be equiangular, for the angles at C and H are right ones: likewise the angle A is equal to FDH; wherefore the remaining angles are also equal. Therefore, as FH, the distance of the two staffs, is to HD, the excess of the longer staff above the shorter; so is DC, the distance of the longer staff from the tower, to CA, the excess of the height of the tower above the longer staff; and thence CA will be found by the rule of three. To which if the length DE be added, you will have the whole height of the tower BA.

Scholium. Another method may be occasionally contrived for measuring an accessible height; as by the given length of the shadow BD (fig. 112), I find out the height AB: for let there be erected a staff CE, perpendicularly, producing the shadow EF; then it will be as EF, the shadow of the staff, is to EC, the staff itself; so is BD, the shadow of the tower, to BA, the height. Though the plane on which the shadow of the tower falls, be not parallel to the horizon, yet if the staff be erected in the same plane, the rule will be the same.

PROB. II. *To measure an accessible height by means of a plain mirror.*

Let AB (fig. 113) be the height to be measured; let the mirror be placed at C, in the horizontal plane BD, at a known distance BC; let the observer go back to D, till he see the image of the summit in the mirror, at a certain point of it, which he must diligently mark; and let DE be the height of the observer's eye. The triangles ABC and EDC, are equiangular; for the angles at D and B are right angles; and ACB, ECD, are equal, being the angles of incidence and reflection of the ray AC; wherefore the remaining angles at A and E, are also equal. Therefore it will be, as CD is to DE, so is CB to BA.

The observer will be more exact, if, at the point D, a staff be placed in the ground perpendicularly, over the top of which the observer may see a point of the glass exactly in a line betwixt him and the tower.

In place of a mirror may be used the surface of water, which naturally becomes parallel to the horizon.

PROB. III. *To measure an accessible height by the geometrical quadrant, theodolite, &c.*

Let the angle C (fig. 114) be found. Then in the triangle ABC, right-angled at B (BC being supposed the horizontal distance of the observer from the tower), having the angle C, and the side BC, the required height will be found by the first case of plain trigonometry. Thus, suppose the angle C. 37° 24′, and the horizontal distance, BC, 116. then the proportion will be as R : T. ∠C :: CB : BA, the height.

The tangent altitude 37° 24′ - -	9.88341
Log. CB 116 - - - - - -	2.06446
Added	11.94787
Radius	10.00000
Height of the object AB 88.69	1.94787

Supposing the observation made on the top of the tower, and the height of the tower to be known, to find the distance of any object on the plane below; it is only the converse of the former case.

You may also, having the base and angles, easily find the hypothenuse AC, or how far it is from the top of the tower to the station, by the second case of right-angled triangles: and it is useful in many cases.

PROB. IV. *To measure an inaccessible height by the geometrical quadrant, &c. at two stations.*

Let the angle ACB be observed (fig. 115); let the observer go from C, to the second station D, in the right line BCD; and after measuring this distance CD, take the angle ADC likewise with the quadrant. Then in the triangle ACD, which is formed by the two visual rays AD, AC, and the distance of the two stations D and C, there is given the angle ADC, with the angle ACD, because the angle ACB was given before; therefore the remaining angle CAD is given likewise. But the distance of the stations C and D is also given; therefore by the second case of obliqueangled trigonometry, the side AC will be found. Wherefore, in the right-angled triangle ABC, all the angles and the hypothenuse AC are given; consequently by the third case of plain trigonometry, the height sought, AB, may be found; as also the distance of the station C, from AB, the perpendicular within the hill or inaccessible height.

Example. Suppose the angle at C 43° 30′, and the angle at D 32° 12′. and the distance CD, betwixt the two stations, 112 feet; then the angle DAC will be 11° 18′, and the angle CAB 46° 30′. Hence for CA, the proportion will be as S. ∠ DAC : DC : : S. ∠ D : CA.

The log. DC 112 - - - -	2.04922
Sine ∠ D 32° 12′ - - - -	9.72663
Added	11.77585
S. ∠DAC 11° 18′ - - - -	9.29214
CA = 304.6 - - - - -	2.48371

Then for AB, the height of the object, it will be as R : S. ∠ ACB :: CA : AB.

As radius - - - - - -	10.00000
is to the sine of 43° 30′ - - -	9.83781
so is CA 304.6 - - - - -	2.48371
to AB 209.7 - - - - -	2.32152

Lastly, for CB, the distance of the object from the nearest station, it will be as R : S. ∠ CAB : : CA : BC.

As radius - - - - - -	10.00000
is to the sine of CAB 46° 30′ - -	9.86056
so is CA 304.6 - - - - -	2.48371
to BC 221 - - - - -	2.34427

If the height of the tower is wanted, the angle BCF (fig. 116) may be found with the quadrant, which being taken from the angle ACB already known, the angle ACF will remain; but the angle FAC was known before; therefore the remaining angle AFC will be known. But the side AC was supposed found by the last problem; therefore in the triangle AFC, all the angles, and one of the sides AC, being known, AF the height of the tower above the hill may be found by trigonometry.

PROB. V. *To measure the distance of two places* A *and* B, *of which one,* A, *is acccssible, by the theodolite,* fig. 117.

Let there be erected at two points, A and C, (sufficiently distant), visible signs; then let the two angles BAC, BCA, be taken by the theodolite. Let the distance of the stations A and C be measured with a chain. Then the third angle being known, and the side AC; therefore, by the second case of oblique trigonometry, the distance required AB will be found.

PROB. VI. *To measure, by the theodolite, &c. the distance of two places, neither of which is accessible,* fig. 118.

Let two stations C and D be chosen, from each of which the places may be seen whose distance is sought; let the angles ACD, BCD, and likewise the angles BDC, BDA, CDA, be measured by the theodolite, &c. and the distance of the stations C and D be measured by a chain, or, if necessary, by the last problem. Now in the triangle ACD, there are given two angles ACD and ADC; therefore the third CAD is likewise given: moreover the side CD is given; therefore by the second case of oblique trigonometry, the side AD will be found. After the same manner, in the triangle BCD, from all the angles, and one side CD given, the side BD is found. Wherefore, in the triangle ADB, from the given sides DA and DB, and the angle ADB contained by them, the side AB (the distance sought) is found too by the fourth case of oblique-angled trigonometry. Note, that it is not necessary that the points A, B, C, and D, be in one plane, and that any triangle is in one plane.

HEIR, is he to whom lands, tenements, or hereditaments, by the act of God and right of blood, descend of some estate of inheritance. Co. Lit. 7. b.

HEIR *apparent.* Here we must observe, that no person can be heir until the death of his ancestor; yet in common parlance, he who stands nearest in degree of kindred to the ancestor, is called even in his life-time, heir apparent. Co. Lit. 8. n. The law also takes notice of an heir apparent, so far as to allow the father to bring an action of trespass for taking away his son and heir, the father being guardian by nature to his son, where any lands descended to him. Co. Lit. 37.

Heir-general: the heir-general, or heir at common law, is he who after his father's or ancestor's death has a right to, and is introduced into, all his land, tenements, and hereditaments; but he must be of the whole blood, not a bastard, alien, &c. None but the heir-general, according to the course of the common law, can be heir to a warrantry, or sue an appeal of the death of his ancestors. Co. Lit. 14.

Customary heir: a custom in particular places varying the rules of descent at common law is good; such is the custom of gravelkind, by which all the sons shall inherit, and make but one heir to their ancestor; but the general custom of gravelkind lands extends to sons only; but a special custom, that if one brother dies without issue, all his brothers may inherit, is good. Co. Lit. 140 a.

To prevent the wrong and injury to creditors by the alienation of the lands descended, &c. by 3 and 4 W. and M. c. 14. it is enacted, that in all cases where any heir at law shall be liable to pay the debt of his ancestor, in regard of any lands, tenements, or hereditaments descending to him, and shall sell, alien, and make over, the same before any action brought or process sued out against him, such heir at law shall be answerable for such debt or debts in action or actions of debt to the value of the said land so by him sold, alienated, or made over; in which case all creditors shall be preferred, as in actions against executors and administrators: and such execution shall be taken out upon any judgment or judgments so obtained against such heirs, to the value of the said land, as if the same were his own proper debts; saving that the lands, tenements, and hereditaments, bona fide aliened before the action brought, shall not be liable to such execution. Provided, that where any action of debt upon any specialty, is brought against any heir, he may plead reins per descent at the time of the original writ brought, or the bill filed against him; any thing therein contained to the contrary notwithstanding. And the plaintiff in such action may reply, that he had lands, tenements, or hereditaments, from his ancestor before the original writ brought, or the bill filed; and if upon issue joined thereupon, it is found for the plaintiff, the jury shall inquire of the value of the lands, tenements, or hereditaments so descended, and thereupon judgment shall be given, and execution shall be awarded as aforesaid; but if judgment is given against such heir, by confession of the action with the assets descended, or upon demurrer, or nihil dixit, it shall be for the debt and damages, without any writ to inquire of the lands, tenements, or hereditaments, so descended.

Before this statute, if the ancestor had devised away the lands, a creditor by specialty had no remedy, either against the heir or devisee. Abr. Eq. 149.

But by the said statute, it is enacted that all wills and testaments, limitations, dispositions, or appointments, of or concerning any manors, messuages, lands, tenements, or hereditaments, or of any rent, profit, term, or charge out of the same, whereof any person at the time of his decease shall be seized in fee simple, possession, reversion, or remainder, or have power to dispose of the same by his last will and testament, shall be deemed and taken only against such creditor as aforesaid, his heirs, successors, executors, administrators and assigns, and every of them, to be fraudulent, and clearly, absolutely, and utterly void, frustrate, and of none effect; any pretence, colour, feigned or presumed consideration, or any other matter or thing, to the contrary notwithstanding.

And for the means, that such creditors may be enabled to recover their said debts, it is farther enacted, that in the cases before-mentioned, every such creditor shall and may maintain his action of debt, upon his said bond and specialties, against the heir at law of such obligor, and such devisee and devisees jointly, by virtue of this act; and such devisee and devisees shall be liable and chargeable for a false plea by him or them pleaded, in the same manner as any heir should have been for false plea by

him pleaded, or for not confessing the lands or tenements to him descended.

Provided, that where there has been or shall be any limitation or appointment, devise or disposition, of any manors, messuages, lands, tenements, or hereditaments, for the raising or payment of any real or just debt, or any portion, sum, or sums of money, for any child or children of any person, other than the heir at law, in pursuance of any marriage-contract or agreement in writing bona fide made before such marriage; the same and every of them shall be in full force, and the same manors, &c. may be holden and enjoyed by every such person, his heirs, executors, administrators, and assigns, for whom the said limitation, appointment, devise, or disposition was made, and by his trustee, his heirs, executors, administrators, and assigns, for such estate or interest as shall be so limited or appointed, devised, or disposed, until such debt or debts, portion or portions, shall be raised, paid, and satisfied; any thing contained in this act to the contrary notwithstanding.

And it is further enacted by the said statute, that all and every devisee and devisees made liable by this act, shall be liable and chargeable in the same manner as the heir at law, by force of this act, notwithstanding the lands, tenements, and hereditaments to him or them devised, shall be aliened before the action brought.

In the construction of this statute it has been holden, that though a man is prevented thereby from defeating his creditors by will, yet any settlement or disposition he shall make in his life-time of his lands, whether voluntary or not, will be good against bond creditors; for that was not provided against by the statute, which only took care to secure such creditors from any imposition which might be supposed in a man's last sickness; but if he gave away his estate in his life-time, this prevented the descent of so much to the heir, and consequently took away their remedy against him, who was only liable in respect of the lands descended; and as a bond is no lien whatsoever on the lands in the hands of the obligor, much less can it be so when they are given away to a stranger. Abr. Eq. 149.

HEIRESS, is a female heir to a person having an estate of inheritance of lands. If there are more than one, they are called coheiresses, or rather, in legal expression, coheirs. The offence of stealing an heiress is founded on the statute 3 Hen. VII. c. 2. which enacts, that if any man shall, for lucre, take any woman, being maid, widow, or wife, and having substance either in goods or lands, or being heir apparent to her ancestor, contrary to her will, and afterwards she be married to such misdoer; or by his consent to another, or defiled; he, his procurors, and abbettors, and such as knowingly receive such woman, shall be deemed principal felons; and by 39 Eliz. c. 9. the benefit of clergy is taken away from principals, procurors, and accessaries before. And it is not material whether a woman so taken contrary to her will, be at last married or defiled with her own consent or not, if she were under the force at the time.

HEIR-LOOMS, are such goods and personal chattles as, contrary to the nature of chattles, shall go by special custom to the heir, along with the inheritance, and not the executor of the last proprietor.

HEISTERIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. The calyx is quinquefid, the petals five; the fruit is a plum on a very large-coloured calyx. There is one species, a tree of Martinico.

HELENIUM, *bastard sun-flower*, a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked in the middle; under the radius, paleaceous; the pappus consists of five short awns; the calyx is simple and multipartite; the florets of the radius semitrifid. The species are: 1. The autumnale, with spear-shaped narrow leaves. 2. The pubescens, with pointed, spear-shaped, sawed leaves. Both these are natives of North America, where they grow wild in great plenty. They rise to the height of seven or eight feet in good ground. The roots, when large, send up a great number of stalks, which branch toward the top; the upper part of the stalk sustains one yellow flower, shaped like the sun-flower, but much smaller, having long rays, which are jagged pretty deep into four or five segments. These plants may be propagated by seeds, or by parting their roots; the latter is generally practised in this country. The best season to transplant and part the old roots is in October, when their leaves are past, or in the beginning of March just before they begin to shoot. They delight in a soil rather moist than dry, provided it is not too strong, or does not hold the wet in winter.

HELEPOLIS, in the ancient art of war, a machine for battering down the walls of a place besieged, the invention of which is ascribed to Demetrius, the Poliorcete. Diodorus Siculus says, that each side of the helepolis was 405 cubits broad, and 90 in height; that it had nine stages, and was carried on four strong solid wheels eight cubits in diameter; that it was armed with large battering rams, and had two roofs capable of supporting them; that in the lower stages there were different sorts of engines for casting stones; and in the middle they had large catapultas for lancing arrows, and smaller in those above, with a number of expert men for working all these machines.

HELIÆA, in Grecian antiquity, was the greatest and most frequented court in Athens, for the trial of civil affairs. The judges who sat in it were at least fifty, but the more usual number was either two or five hundred. When causes of great moment were to be tried, it was customary to call in the judges of the other courts: sometimes a thousand were called in, and then two courts are said to have been joined: sometimes fifteen hundred or two thousand were called in, and then three or four courts met together. They had cognizance of civil affairs of the greatest weight and importance, and were not permitted to give judgment till they had taken a solemn oath to do it with impartiality, and to give sentence according to the laws, &c.

HELIACAL, in astronomy, a term applied to the rising or setting of the stars, or, more strictly speaking, to their emersion out of and immersion into the rays and superior splendor of the sun.

A star is said to rise heliacally, when after having been in conjunction with the sun, and on that account invisible, it comes to be at such a distance from him, as to be seen in the morning before sun-rising; the sun, by his

apparent motion, receding from the star towards the east: on the contrary, the heliacal setting is when the sun approaches so near a star as to hide it with his beams, which prevent the fainter light of the star from being perceived, so that the terms apparition and occultation would be more proper than rising and setting.

All the fixed stars in the zodiac, as also the superior planets, Mars, Jupiter, and Saturn, rise heliacally in the morning, a little before sun-rising, and a few days after they have set cosmically. Again, they set heliacally in the evening, a short time before their achronycal setting. But the moon, whose motion eastward is always quicker than the apparent motion of the sun, rises heliacally in the evening, after the new moon, and sets heliacally in the morning, when old and approaching to a conjunction with the sun.

The inferior planets, Venus and Mercury, which sometimes seem to go westward from the sun, and sometimes again have a quicker motion eastward, rise heliacally in the morning, when they are retrograde; but when direct in their motions, they rise heliacally in the evening. The heliacal rising or setting of the moon happens when she is 17° distant from the sun; but for the other planets 20° are required; and for the fixed stars more or less according to their magnitude.

HELIANTHUS, *the great sun-flower*, a genus of the polygamia frustanea order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is paleaceous and plane; the pappus diphyllous; the calyx imbricated; the scales standing a little out at the tops. There are 12 species, most of which are now very common in gardens, and are all of them natives of America. They are all very hardy, and will thrive in almost any soil or situation. They may be propagated either by seeds or by parting their roots, but most of them are annual. The Jerusalem artichoke belongs to this genus.

HELICOID PARABOLA, or the *parabolic spiral*, is a curve arising from the supposition that the common or Apollonian parabola is bent or twisted, till the axis come into the periphery of a circle, the ordinates still retaining their places and perpendicular positions with respect to the circle, all these lines still remaining in the same plane. Thus, the axis of a parabola being bent into the circumference BCDM (Plate LXXII. Miscell. fig. 119.), and the ordinates CF, DG, &c. still perpendicular to it, then the parabola itself, passing through the extremities of the ordinates, is twisted into the curve BFG, &c. called the helicoid, or parabolic spiral.

Hence all the ordinates CF, DG, &c. tend to the centre of the circle, being perpendicular to the circumference.

Also, the equation of the curve remains the same as when it was a parabola; viz. putting $x =$ any circular absciss BC, and $y =$ CF the corresponding ordinate, then is $px = y^2$, where p is the parameter of the parabola.

HELICONIA, a genus of the monogynia order, in the pentandria class of plants. The spatha is universal and partial; there is no calyx; the corolla has three petals, and the nectarium two leaves; the capsule is three grained. There are three species, beautiful herbaceous stove plants from South America and the West Indies.

HELICTERES, *the screw-tree*, a genus of the decandria order, in the gynandria class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is monophyllous and oblique; there are five petals, and the nectarium consists of five petal-like leaflets; the capsules are intorted or twisted inwards. There are nine species, all natives of warm climates. They are shrubby plants, rising from five to fourteen feet in height adorned with flowers of a yellow colour. They are propagated by seeds, but are tender, and in cold countries must be kept in a stove during the winter.

HELIOCARPUS, a genus of the digynia order, in the dodecandria class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is tetraphyllous; the petals four; the styles simple; the capsule bilocular, compressed, and radiated lengthwise on each side. There is one species, a tree of La Vera Cruz.

HELIOCENTRIC *latitude of a planet*, the inclination of a line drawn between the centre of the sun and the centre of a planet, to the plane of the ecliptic, which may be thus determined.

If the circle FGH (Plate LXXII. Miscell. fig. 121.) represent the orbit of the earth round the sun, and the inner one ANBn, be so placed as to incline to the plane of the other (on which account it appears in the form of an ellipsis), then when the planet is in the node n, it will appear in the ecliptic, and so have no latitude. But if it move to P, then, being seen from the sun, it will appear to decline from the ecliptic, or to have latitude; and the inclination of the line SP to the plane of the ecliptic, is called the planet's heliocentric latitude; the measure of which is the angle PS p, supposing the line P p to be perpendicular to the plane of the ecliptic.

This heliocentric latitude will be continually increasing till the planet come to the point A, which they call the limit or utmost extent of it; and then it will decrease again till it reach the other node N, when it will have no latitude; after which it will increase again, till it come to B, or its utmost latitude; and, lastly decrease again, till the planet come to be in n, whence it set out.

HELIOCENTRIC *place of a planet*, in astronomy, the place of the ecliptic in which the planet would appear to a spectator placed at the centre of the sun.

The ingenious Dr. Halley gives the following method to find the heliocentrical places of a planet, and its distances from the sun, which supposes only that the periodical time of the planet is known. Let KLB (fig. 120.) be the orbit of the earth, S the sun, P the planet, or rather the point in the plane of the ecliptic, in which the perpendicular let fall from the planet meets that plane. And first when the earth is in K, observe the geocentric longitude of the planet, and having the theory of the earth, we have the apparent longitude of the sun, and, consequently, the angle PKS. The planet after it has completed an entire revolution, returns again to the point P, at which time suppose the earth in L; and there again, let the planet be observed, and find the angle PLS, the planet's elongation from the sun. Having the times of observations, we have the places of the earth in the ecliptic, or the points K and L; and consequently, the angle LSK, and the sides LS and SK: wherefore we shall have the angles SKL and SLK, and the side LK. From the known angles SKP and SLP, take away the known angles SKL

and SLK, and we shall have the angles PKL and PLK known; therefore in the triangle PLK, having all the three angles, and the side LK, we shall find the side PL; and in the triangle PLS, having the sides PL and LS, and the intercepted angle PLS, we shall have the angle LSP, which determines the heliocentric place, and its distance from the node according to the ecliptic, as also the side SP. But as the tangent of the geocentric latitude is to the tangent of the heliocentric, so is the curtate distance of the planet from the sun to its curtate distance from the earth. But as the geocentric latitude may be found by observation, the heliocentric latitude will also be found; by which, and the curtate distance of the planet from the sun, we can find the true distance.

HELIOCOMETES, a phenomenon sometimes observed about sun-setting; being a large luminous tail or column of light proceeding from the body of the sun, and dragging after it, not unlike the tail of a comet; whence the name.

HELIOPHILA, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. There are two nectaria recurvated towards the vesicular base of the calyx. There are ten species, all herbaceous plants of the Cape.

HELIOSCOPE, in optics, a sort of a telescope, peculiarly fitted for viewing the sun, without hurting the eyes. See OPTICS.

As the sun may be viewed through coloured glasses, without hurt to the eyes, if the object and eye-glasses of a telescope are made of coloured glass, as red or green, such a telescope will become an helioscope. But Mr. Huygens only used a plain glass, blacked at the flame of a candle on one side, and placed between the eye-glass and the eye, which answers the design of an helioscope very well.

HELIOSTATA, in optics, an instrument invented by the late learned Dr. S. Gravesande, who gave it this name, from its fixing apparently the rays of the sun in an horizontal direction across the dark chamber, all the while it is in use.

HELIOTROPE, a precious stone of a green colour, streaked with red veins. Pliny says it is thus called, because, when cast into a vessel of water, the sun's rays falling on it seem to be of a blood-colour; and that, when out of the water, it gives a faint reflection of the figure of the sun, and is proper to observe eclipses of the sun as a helioscope. The heliotrope is also called oriental jasper, on account of its ruddy spots. It is found in the East Indies, as also in Ethiopia, Germany, &c. According to Dr. Thompson, the colour of this stone is different shades of green, often stained or striped with olive, yellow, and red. Found in mass, and in angular pieces. Specific gravity 2.6. Brittle, infusible before the blow-pipe.

HELIOTROPIUM, *turnsole*, a genus of the polygynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. The corolla is salver-shaped and quinquefid, with lesser dents interjected alternately; the throat closed up by small arches formed in the corolla itself. There are 24 species, all of them natives of warm countries. Only one, called the tricoccum, grows in Europe, and is a native of France, Spain, and Italy. It is only remarkable for the property of its berries. See COLOUR-MAKING.

HELIX, in geometry, the same with spiral. In architecture some authors make a difference between the helix and the spiral. A stair-case, according to Daviler, is an helix, or is helical, when the stairs or steps wind round a cylindrical newel; whereas the spiral winds round a cone, and is continually approaching nearer and nearer its axis.

HELIX, *the snail*, in zoology, a genus belonging to the order of vermes testacea. The shell consists of one spiral, brittle, and almost diaphanous valve; and the aperture is narrow. There are 60 species, principally distinguished by the figure of their shells. They are of various sizes, from that of a small apple to less than half a pea. Some of them live on land, frequenting woods and gardens, or inhabiting clefts of rocks and dry sand-banks. Others of them are aquatic, inhabiting ponds, deep rivers, and the ocean. The principal species are,

The janthina, with a violet-coloured shell, is remarkable for the extreme thinness of its texture, which breaks with the least pressure, and seems therefore entirely calculated to keep the open sea, or at least to shun rocky shores. It inhabits the seas of Europe, especially the Mediterranean, those of Asia and Africa, and also the ocean. The living animal, when touched, exudes a juice which stains the hands of a violet-colour. Dr. Hawkesworth, in his Account of Cooke's Voyage, mistakes this shell for that which yielded the purpura of the ancients. But whoever looks into Pliny, can never have the least idea that the thin shell aforementioned could be the same with it. They had several shells which yielded the purple dye; but these were all rock-shells, and very different both in figure and hardness from the little helix janthina, which is not calculated for the neighbourhood of rocks.

2. The pomatia, or exotic snail, with five spires, most remarkably ventricose, and fasciated with a lighter and deeper brown, is a native of France, where it inhabits the woods, but has been naturalized in England, where it inhabits the woods in the southern counties. It was introduced, it is said; by sir Kenelm Digby, whether for medical purposes, or as food, is uncertain: tradition says, that to cure his beloved wife of a decay was the object. They are quite confined to the southern counties. An attempt was made to bring them into Northamptonshire, but they would not live there. These are used as a food in several parts of Europe during Lent, and are preserved in an escargatoire, or a large place boarded in, with a floor covered half a foot deep with herbs, in which the snails nestle and fatten. They were also a favourite dish with the Romans, who had their cochlearia, a nursery similar to the above. Fulvius Hirpinus was the first inventor of this luxury, a little before the civil wars between Cæsar and Pompey. The snails were fed with bran and sodden wine. If we could credit Varro, they grew so large that the shells of some would hold ten quarts! People need not admire the temperance of the supper of the younger Pliny, which consisted of only a lettuce. three snails. two eggs. a barley-cake, sweet wine and snow, in case his snails bore any proportion in size

to those of Hirpinus. Its name is derived not from any thing relating to an orchard, but from πωμα, an operculum, it having a very strong one. This seems to be the species described by Pliny, lib. viii. c. 39. which he says was scarce; that it covered itself with the opercle, and lodged under ground; and that they were at first found only about the maritime Alps, and more lately near Velitræ.

3. The hortensis, or garden-snail, is in form like the last, but less, and not umbilicated and clouded, or mottled with browns. It abounds with a viscid slimy juice, which it readily gives out by boiling in milk or water, so as to render them thick and glutinous. The decoctions in milk are apparently very nutritious and demulcent, and have been recommended in a thin acrimonious state of the humours, in consumptive cases and emaciations.

The eyes of snails are lodged in their horns, one at the end of each horn, which they can retract at pleasure. The manner of examining these eyes, which are four in number, is this: When the horns are out, cut off nimbly the extremity of one of them; and placing it before the microscope, you may discover the black spot at the end to be really a semiglobular eye. The dissection of this animal is very curious; for by this means the microscope not only discovers the heart beating just against the round hole near the neck, which seems the place of respiration, but also the liver, spleen, stomach, and intestines, with the veins, arteries, mouth and teeth, are plainly observable. The intestines of this creature are green, from its eating herbs, and are branched all over with fine capillary white veins; the mouth is like a hare's or rabbit's, with four or six needle-teeth, resembling those of leeches, and of a substance like horn. Snails are all hermaphrodites, having both sexes united in each individual. They lay their eggs with great care in the earth, and the young ones are hatched with shells completely formed. Cutting off a snail's head, a little stone appears, which is supposed to be a great diuretic, and good in all nephritic disorders. Immediately under this stone the heart is seen beating: and the auricles are evidently distinguishable, and are membranous, and of a white colour: as are also the vessels which proceed from them.

Snails discharge their excrements at a hole in their neck; they also breathe by this hole, and their parts of generation are situated very near it.

So small an animal as the snail is not free from the plague of supporting other smaller animals on its body; and as in other animals we find these secondary ones either living on their surface, as lice, &c. or only in the intestines, as worms, it is very remarkable that the snail is infested in both these manners, lice being found sometimes on the surface of its body, and worms sometimes within its intestines. There is a part of the common garden snail, and of other of the like kinds, commonly called the collar. This surrounds the neck of the snail, and is considerably thick, and is the only part that is visible when the animal is retired quietly into its shell. In this state of the animal these insects which infest it are usually seen in considerable numbers marching about very nimbly on this part; besides, the snail, every time it has occasion to open its anus, gives them a place by which to enter into its intestines, and they often seize the opportunity.

Snails are great destroyers of fruit in our gardens, especially the better sorts of wall-fruit. Lime and ashes sprinkled on the ground where they most resort will drive them away, and destroy the young brood of them. It is a common practice to pull off the fruit they have bitten; but this should never be done, for they will eat no other till they have wholly eaten up this if it is left for them. See Plate LXVII. Nat. Hist. fig. 223.

Helix. See Anatomy.

HELLEBORUS, *hellebore*, a genus of the polygynia order, in the polyandria class of plants, and in the natural method ranking under the 26th order, multisiliquæ. There is no calyx; but 5 or more petals; the nectaria are bilabiated and tubular; the capsules polyspermous, and a little erect. There are seven species, the most remarkable of which is the niger, commonly called Christmas-rose. It has roots composed of many thick fleshy spreading fibres, crowned by a large cluster of lobed leaves, consisting each of seven or eight obtuse fleshy lobes, united to one foot-stalk; and between the leaves several thick fleshy flower-stalks, three or four inches high, surmounted by large beautiful white flowers, of five roundish petals, and numerous filaments, appearing in winter, about or soon after Christmas.

This plant may be propagated either by seeds or parting the roots. It prospers in the open borders, or may be planted in pots to move when in bloom, in order to adorn any particular place; but it always flowers fairest and most abundantly in the front of a warm sunny border. The plants may be removed, and the roots divided for propagation, in September, October, or November; but the sooner in autumn it is done, the stronger will the plants flower at their proper season.

The root of this plant was anciently used as a cathartic. The taste of it is acrid and bitter. Its acrimony, as Dr. Grew observes, is first felt on the tip of the tongue, and then spreads itself immediately to the middle, without being much perceived in the intermediate part. On chewing the root for a few minutes, the tongue seems benumbed, and affected with a kind of paralytic stupor, as when burnt by eating any thing too hot. The fibres are more acrimonious than the head of the root whence they issue. Black hellebore root, taken from 15 to 30 grains, proves a strong cathartic, and as such has been celebrated for the cure of maniacal disorders, and such also as were attributed to what the ancients called the atra bilis. In mania, however, this root appears by no means to be possessed of any specific power. It does not indeed appear that our black hellebore acts with so much violence as that of the ancients, whence many have supposed it to be a different plant; and indeed the descriptions which the antients have left us of their hellebore, do not agree with those of any of the sorts usually taken notice of by modern botanists. Another species has been discovered in the eastern countries, which Tournefort distinguishes by the name of helleborus niger orientalis, amplissimo folio, caule præalto, flore purpurascente, and supposes to be the true ancient hellebore, from its growing in plenty about Mount Olympus, and in the island of Anticyra, celebrated of old for the production of this antimaniacal drug: he relates, that a scruple of this sort given

for a dose, occasioned convulsions. Our hellebore is looked upon principally as in alterative; and is sometimes employed in small doses for promoting the uterine and urinary discharges, &c. It proves a powerful emmenagogue in plethoric habits, where steel is ineffectual or improper. In some parts of Germany a species of black hellebore has been made use of, which frequently produced violent, and sometimes deleterious effects. It appears to be the feted kind of Linnæus, called in English settlewort, setterwort, or bastard hellebore. The roots of this may be distinguished from those of the true kind, by their being less black.

2. The hyemalis, with a beautiful yellow flower, which is the common harbinger of spring.

HELM *of a ship*, is a piece of timber fastened into the rudder, which comes forward into the steerage, or place where the person at the helm steers the ship, by holding the whipstaff in his hand, where it joined to the helm. They begin, however, to be left off, steering-wheels being used in their room.

There are several terms in the sea language relating to the helm: as, bear up the helm; that is, let the ship go more large before the wind: helm a mid-ship or right the helm; that is, keep it even with the middle of the ship: port the helm, put it over to the left side of the ship: starboard the helm, put it on the right side of the ship. See SHIP-BUILDING.

HELMET, an ancient defensive armour worn by horsemen both in war and in tournaments. It covered both the head and face, only leaving an aperture in the front secured by bars, which was called the visor.

It is still used in heraldry by way of crest over the shield or coat of arms, in order to express the different degrees of nobility by the different manner in which it is borne. Thus a helmet in profile is given to gentlemen and esquires: to a knight, the helmet standing forward and the beaver a little open: the helmet in profile and open, with bars, belongs to all noblemen under the degree of a duke; and the helmet forward and open, with many bars, is assigned to kings, princes, and dukes. There is generally but one helmet upon a shield; but sometimes there are two, and even three: if there are two, they ought to face each other; and if three, the middlemost should stand directly forward, and the other two on the sides facing towards it.

HELMINTHOLITHUS, in natural history, a name given by Linnæus to petrified bodies resembling worms. Of these he reckons four genera. 1. Petrified lithophyta, found in the mountains of Sweden. 2. Petrified shells. 3. Petrified zoophytes. 4. Petrified reptiles. See LITHOPHYTA, &c.

HELONIAS, a genus of the trigynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariæ. The corolla is hexapetalous; there is no calyx; and the capsule is trilocular. There are two species; herbs of America.

HELVELIA, a genus of the class and order cryptogamia fungi. There are two species, natives of this country.

HELXINE. See POLYGONUM.

HEMATOPUS, in ornithology, a genus of the grallæ order. The generic character is: the bill compressed, the lip an equal wedge; nostrils linear; tongue a third part as long as the bill; feet formed for running, three-toed, cleft.

The H. ostrolegus, or oyster-catcher, inhabits almost every sea-shore, is sixteen and a half inches long, feeds on marine worms and insects, but chiefly on oysters and limpets, which it extracts from the shell with great dexterity. Eggs, four or five; colour, olive-yellow, with irregular purplish spots. This is the only species. See Plate LXVII. Nat. Hist. fig. 219.

HEMEROBIUS, in zoology, a genus of insects of the neuroptera order, the characters of which are these: the mouth is furnished with two teeth; the palpi are four; the wings are deflected but not plaited; and the antennæ are bristly and longer than the breast. There are 15 species, principally distinguished by their colours. This insect takes the name of hemerobius from the shortness of its life, which, however, continues several days. In the state of larva it is a great devourer of plant-lice, for which it has had bestowed upon it the appellation of lion of the plant-lice. The hemerobii, even after their transformation, preserve their carnivorous inclination. Not satisfied with making war upon the plant-lice, who tamely let themselves be devoured, they do not spare each other. The eggs of this insect are borne upon small pedicles, which are nothing but a gum spun out by the hemerobius by raising up the hinder part of its abdomen, and by that means the egg remains fastened to the upper part of the thread. Those eggs are deposited upon leaves, and set in the form of bunches. They have been taken for parasitic plants. The larva, when hatched, finds there its food in the midst of plant-lice. In 15 or 16 days it has attained to its full growth. With its spinning-wheel at its tail, it makes itself a small, round, white, silky cod, of a close texture. In summer, at the end of three weeks, the hemerobius issues forth with its wings; but when the cod has not been spun till autumn, the chrysalis remains in it the whole winter, and does not undergo its final metamorphosis till the ensuing spring. The flight of this insect is heavy: some species have an excrementitious smell. One goes by the name of the water-hemerobius, because it lives mostly at the water-side. See Plate LXVII. Nat. Hist. fig. 224.

HEMEROCALLIS, *day-lily*, or *lily-asphodel*, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariæ. The corolla is campanulated, with the tube cylindrical; the stamina declining downward. There are five species, of which two are common, viz.

1. The flava, or yellow day-lily, with strong fibrous roots, sending up large hollow keel-shaped leaves, two feet long, upright, leafless firm stalks, two feet high, dividing at top into several foot-stalks, each terminated by one large liliaceous yellow flower, of an agreeable odour. Of this there is a variety called the hemerocallis minor, or small yellow day-lily.

2. The fulva, reddish, or copper-coloured day-lily, has roots composed of strong fleshy fibres, and large oblong tubes; radical, keel-shaped, hollow, pointed leaves, a yard long, reflected at top, with leafless stalks, three or four feet high, and large copper-coloured liliaceous flowers. These have large stamina, charged with a kind of brown-coloured farina, which, on being touched

or smelled to, is discharged in great plenty all over the hands and face. Both these species are hardy, and will thrive any where. They may be easily propagated by parting their roots in autumn, or almost any time after flowering, or before they begin to flower.

3. The japonica is a greenhouse plant, producing beautiful white flowers.

HEMERODROMI, in Grecian antiquity, centinels and guards appointed for the security and preservation of cities and other places. They went out of the city every morning as soon as the gates were opened, and kept patrolling all day about the place: sometimes also making excursions further into the country, to see that there were no enemies lying in wait to surprise them.

Hemerodromi were also a sort of couriers among the ancients, who only travelled one day, and then delivered their packets or despatches to a fresh man, who run his day, and so on to the end of the journey.

HEMICYCLE. See Architecture.

HEMIMERIS, a genus of the angiospermia order, in the didynamia class of plants. The capsule is bilocular, with one of the cells more gibbous than the other; the corolla is wheel-shaped, with one division greater, and inverse heart-shaped; the interstice of the divisions nectar-bearing. There are three species, herbaceous plants of the Cape.

HEMINA, in Roman antiquity, a liquid measure which, according to Arbuthnot, was equal to half a wine-pint English measure; its contents being 2.818 solid inches.

HEMIONITIS, a genus of the natural order of filices, belonging to the cryptogamia class of plants. The fructifications are in lines, decussating or crossing each other. There are eight species, natives of the West Indies.

HEMIPLEGIA. See Medicine.

HEMIPTERA, derived from ἡμισυς, *half, wing,* πτερον, in the Linnæan system, the second order of insects, comprehending twelve genera, viz. the blatta, mantis, gryllus, fulgora, cicada, notonecta, nepa, cimex, aphis, chermes, coccus, and thrips, and a great number of species.

HEMISPHERE, in geometry, the half of a globe or sphere, when it is supposed to be cut through its centre in the plane of one of its great circles. Thus the equator divides the terrestrial globe into the northern and southern hemisphere: in the same manner the meridian divides the globe into the eastern and western hemisphere; and the horizon into two hemispheres, distinguished by the epithets upper and lower. The centre of gravity of an hemisphere is five-eights of the radius distant from the vertex.

Hemisphere is also used to denote a projection of half the terrestrial globe, or half the celestial sphere, on a plane, and frequently called planisphere.

HEMISTICH, in poetry, denotes half a verse, or a verse not completed. Of this there are frequent examples in Virgil's Æneid; but whether they were left unfinished by design or not, is disputed among the learned: such are *Ferro accincta vocat,* Æn. II. v. 614. And, *Italiam non sponte sequor,* Æn. IV. v. 361.

In reading common English verses, a short pause is required at the end of each hemistich, or half verse.

HEMLOCK. See Cicuta.

HEMP and Flax. No hemp or flax is to be watered in any river, running water, stream, brook, or pond, where beasts are used to be watered, but only in their several ponds for that purpose, on pain of 20*s*. 33 Hen. VIII. c. 17.

Any persons may, in any place, corporate town, privileged or unprivileged, set up manufactories of hemp or flax; and persons coming from abroad, using the trade of hemp or flax-dressing, and of making thread, weaving cloth made of hemp or flax, or making tapestry hangings, twine or nets for fishery, cordage, &c. after three years, shall have the privilege of natural-born subjects. 15 Car. II. c. 15.

HEN. See Phasianus.

HENDECAGON, in geometry, a figure that has eleven sides, and as many angles. In fortification, hendecagon denotes a place defended by eleven bastions.

HENOTICON, in church history, a decree or edict of the emperor Zeno, made at Constantinople, in the year 482, by which he pretended to reconcile all parties under one faith.

HEPAR, a name formerly given to the combination of sulphur and alkali. It is now called sulphuret of potass.

HEPATIC gas, the old name for the gas separated from sulphuret of alkali. It is now called sulphurated hydrogen gas.

HEPATICA. See Anemone.

HEPATITIS. See Medicine.

HEPTAGON, in geometry, a figure of seven sides and seven angles. When those sides and angles are all equal, the heptagon is said to be regular, otherwise it is irregular.

In a regular heptagon, the angle C, Plate LXXII. Miscel. fig. 122, at the centre is $= 51^\circ\frac{3}{7}$, the angle DAB of the polygon is $= 128^\circ\frac{4}{7}$, and its half CAB $= 64^\circ\frac{2}{7}$. Also the area is = the square of the side $AB^2 \times 3.6339124$, or $= AB^2 \times \frac{7}{4}t$, where t is the tangent of the angle CAB of $64^\circ\,\frac{2}{7}$ to the radius 1; or t is the root of the equation; $t^{12} - 26t^{10} + 143t^8 - 245t^6 + 143t^4 - 26t^2 + 1 = 0$; or $t = \sqrt{\frac{1+x}{1-x}} = \frac{1+\sqrt{1-y^2}}{y} = \frac{y}{1-\sqrt{1-y^2}}$, where the value of x and y are the roots of the equations

$$x^6 - \tfrac{5}{4}\,x^4 + \tfrac{3}{8}\,x^2 - \tfrac{1}{46} = 0,$$
$$y^6 = \tfrac{7}{4}\,y^4 + \tfrac{7}{8}\,y^2 - \tfrac{7}{64} = 0.$$

Heptagon, in Fortification, a place fortified or strengthened with seven bastions for its defence.

HEPTAGONAL Numbers, are a kind of polygonal numbers in which the difference of the terms of the corresponding arithmetical progression is 5. Thus,

Arithmeticals, 1, 6, 11, 16, 21, 26, &c.
Heptagonals, 1, 7, 18, 34, 55, 38, &c.

where the heptagonals are formed by adding continually the terms of the arithmeticals, above them, whose common difference is 5.

One property, among many others, of these heptagonal numbers is, that if any one of them be multiplied by 40, and to the product add 9, the sum will be a square number.

Thus $1 \times 40 + 9 = 49 = 7^2$;
and $7 \times 40 + 9 = 289 = 17^2$;
and $18 \times 40 + 9 = 729 = 27^2$;
and $34 \times 40 + 9 = 1369 = 37^2$; &c.

Where it is remarkable that the series of squares so formed is 7^2, 17^2, 27^2, 37^2, &c., the common difference of whose roots is 10, the double of the common difference of the arithmetical series from which the heptagonals are formed. See POLYGONALS.

HEPTAMERIS, in music, the seventh part of a meris, being, according to M. Sauveur, the forty-third part of the octave.

HEPTANDRIA, from ἑπτα, septem, and ανηρ, a man, the seventh class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which have seven stamina or male organs. The orders are four, derived from the number of styles or female organs. See BOTANY.

HEPTANGULAR FIGURE, in geometry, is one that has seven angles, and therefore also seven sides.

HERACLEUM, a genus of the pentandria digynia class of plants, the general flower of which is difform and radiated; the single flowers of the disc consist each of five equal petals, but those of the radius consist of five unequal petals. The fruit is elliptic, compressed, and striated on each side in the middle, and contains two oval compressed seeds. To this genus belongs the sphondylium or cow's parsnep of authors. There are six species.

HERACLIDÆ, or *return of the* HERACLIDÆ *into Peloponnesus*, in chronology, a famous epocha, that constitutes the beginning of prophane history; all the time preceding that period being accounted fabulous. This return happened in the year of the world 2862, an hundred years after they were expelled, and eighty after the destruction of Troy.

HERALD, is an officer at arms, whose business is to denounce war, proclaim peace, or be otherwise employed by the king in martial messages or other business.

Heralds are the judges and examiners of gentlemen's coats of arms, and preservers of genealogies; and they marshal all solemnities at the coronation of princes, and funerals of great persons.

HERALDRY, the science which teaches how to blazon, or explain in proper terms, all that belongs to coats of arms; and how to marshal, or dispose regularly, divers arms on a field.

Arms, or coats of arms, are hereditary marks of honour, made up of fixed and determined colours and figures, granted by sovereign princes, as a reward for military valour, or some signal public service performed. These are intended to denote the descent and alliance of the bearer, or to distinguish states, cities, societies, &c. civil, ecclesiastical, and military.

Men in all ages have made use of figures of living creatures, or symbolical signs, to denote the bravery and courage either of their chief or nation, to render themselves the more terrible to their enemies, and even to distinguish themselves or families, as names do individuals. Thus the Egyptians bore an ox, the Athenians an owl, the Goths a bear, the Romans an eagle, the Franks a lion, and the Saxons a horse: the last is still borne in the arms of his present Britannic majesty. As to hereditary arms of families, William Camden, sir Henry Spelman, and other judicious heralds, agree, that they began no sooner than towards the latter end of the eleventh century.

With tournaments first came up coats of arms: which were a sort of livery, made up of several lists, fillets, or narrow pieces of stuff of many colours, from whence came the fess, the bend, the pale, &c. which were the original charges of family-arms: for they who never had been to tournaments had not such marks of distinction. They who enlisted themselves in the croisados took up also several new figures hitherto unknown in armorial ensigns; such as alerions, bezants, escalop-shells, martlets, &c. but more particularly crosses, of different colours for distinction's sake. From this it may be concluded, that heraldry, like most human inventions, was insensibly introduced and established; and that, after having been rude and unsettled for many ages, it was at last methodized, perfected, and fixed, by the croisades and tournaments.

These marks of honour are called arms, from their being principally and first worn by military men at war and tournaments, who had them engraved, embossed, or depicted on shields, targets, banners, or other martial instruments. They are also called coat of arms, from the custom of the ancients embroidering them on the coats they wore over their arms, as heralds do to this day.

Arms are distinguished by different names, to denote the causes of their bearing; such as arms of dominion; of pretension; of concession; of community; of patronage; of family; of alliance; of succession.

Arms of dominion, or sovereignty, are those which emperors, kings, and sovereign states do constantly bear; being annexed to the territories, kingdoms, and provinces, they possess. Thus the three lions are the arms of England, the harp those of Ireland, &c.

Arms of pretension are those of such kingdoms, provinces, or territories, to which a prince or lord has some claim, and which he adds to his own, although the said kingdom, or territories may be possessed by a foreign prince or lord. Thus the kings of England have quartered the arms of France with their own ever since Edward III. laid claim to the kingdom of France, which happened in the year 1330, on account of his being son to Isabella, sister to Charles the Handsome, who died without issue.

Arms of concession, or augmentation of honour, are either entire arms, or else one or more figures, given by princes as a reward for some extraordinary service. We read in history that Robert Bruce, king of Scotland, allowed the earl of Wintoun's ancestor to bear, in his coat-armour, a crown supported by a sword, to show that he, and the clan Seaton, of which he was the head, supported his tottering crown.

Arms of community are those of bishoprics, cities, universities, academies, societies, companies, and other bodies corporate.

Arms of patronage are such as governors of provinces, lords of manors, patrons of benefices, &c. add to their family-arms, as a token of their superiority, rights, and jurisdiction. These arms have introduced into heraldry, castles, gates, wheels, ploughs, rakes, harrows, &c.

Arms of family, or paternal arms, are those that belong to one particular family, that distinguish it from others,

and which no person is suffered to assume without committing a crime, which sovereigns have a right to restrain and punish.

Arms of alliance are those which families or private persons take up and join to their own, to denote the alliances they have contracted by marriage. This sort of arms is either impaled, or borne in an escutcheon of pretence, by those who have married heiresses.

Arms of succession are such as are taken up by them who inherit certain estates, manors, &c. either by will, entail, or donation, and which they either impale, or quarter with their own arms; which multiplies the titles of some families out of necessity, and not through ostentation, as many imagine.

These are the eight classes under which the different sorts of arms are generally ranged; but there is a sort which blazoners call assumptive arms, being such as are taken by the caprice or fancy of upstarts, though of ever so mean extraction, who, being advanced to a degree of fortune, assume them without a legal title.

The essential and integral parts of arms are these: 1. The escutcheon. 2. The tinctures. 3. The charges. 4. The ornaments.

Of the shield or escutcheon.—The shield or escutcheon is the field or ground whereon are represented the figures that make up a coat of arms: for these marks of distinction were put on bucklers or shields before they were placed on banners, standards, flags, and coat-armour; and wherever they may be fixed, they are still on a plane or superfices whose form resembles a shield.

Shields, in heraldry called escutcheons or scutcheons, from the Latin word scutum, have been, and still are, of different forms, according to different times and nations. Amongst ancient shields, some were almost like a horse-shoe, such as is represented by a few of the figures of escutcheons; others triangular, somewhat flat or rounded at the bottom. The English, French, Germans, and other nations, have their escutcheons formed different ways, according to the carver's or painter's fancy: of these various examples are contained in the plates of heraldry. But the shield of maids, widows, and of such as are born ladies, and are married to private gentlemen, is of the form of a lozenge (See Plate LXVI.)

Armorists distinguish several parts or points in escutcheons, in order to determine exactly the position of the bearings they are charged with; they are here denoted by the first nine letters of the alphabet, ranged in the following manner (See Plate LXV.)

The knowledge of these points is of great importance, and ought to be well observed, for they are frequently occupied with several things of different kinds. It is necessary to observe, that the dexter side of the escutcheon is opposite to the left hand, and the sinister side to the right hand of the person that look on it.

Distinction of houses. These distinctions inform us how the bearer of each is descended from the same family; they also denote the subordinate degrees in each house from the original ancestors, viz.

First house. For the heir or first son the label; second son the crescent; third son the mullet; fourth son the martlet; fifth son the annulet; sixth son the fleur-de-lis.

Second house. The crescent, with the label on it, for the first son of the second son. The crescent on the crescent for the second son of the second son of the first house, &c. See the Plate.

By the *tinctures* or colours is meant that variety of hue of arms common both to shields and their charges: the colours generally used are red, blue, sable, vert, purpure. Note, yellow and white, termed or and argent, are metals; these colours are represented in engravings by dots and lines, as in the Plate.

Or is expressed by dots.

Argent is plain.

Gules, by perpendicular lines.

Azure, by horizontal lines.

Sable, by perpendicular and horizontal lines crossing each other.

Vert, by diagonal lines from the dexter chief to the sinister base point.

Purpure, by diagonal lines from the sinister chief to the dexter base point.

Furs.—There are different kinds, and represent the hairy skins of certain animals, prepared for the linings of robes of state; and anciently shields were covered with furred skins: they are used in coats of arms, viz.

Ermine, is black spots on a white field.

Ermines, is a field black with white spots.

Erminois, is a field gold with black spots.

Vair, is white and blue, represented by figures of small escutcheons arranged in a line, so that the base argent is opposite to the base azure.

Potent-counter-potent, is a field covered with figures like crutch heads. See Plate.

Charges, are whatsoever bearings or figures are borne in the field of a coat of arms.

Rampant, signifies the lion standing erect on one of the hind legs.

Rampant-gardant, is a lion standing on his hind leg, looking full-faced.

Rampant-regardant, standing upon his hind leg, looking back towards his tail.

Passant: this term is to express the lion in a walking position.

Sejant, for the lion sitting, as the example.

Saliant, is when the lion is leaping or springing forward, as the example.

Couchant, is a lion lying at rest, with the head erect.

Passant-gardant, for a beast, when walking, with its head looking full-faced.

Couped, cut off smooth and even, as the example.

Erased, signifying torn or plucked off, as the example.

Demy, is the half of any charge, as the example, a demy lion.

Dormant, for sleeping with its head resting on its fore paws.

Partition lines, by which is understood a shield divided or cut through by a line or lines, either horizontal, perpendicular, diagonal, or transverse: the engraved examples are the crooked lines of partition, viz. engrailed, invecked, wavy, nebule, imbattled, raguly indented, dancette, dove tail. See Plate LXV.

Roundels are round figures, much used in arms: the English heralds vary their names according to their colour, thus:

Or,	is termed a	Bezant.
Argent,		Plate.
Gules,		Torteaux.
Azure,		Hurt.
Sable,		Pellett.
Vert,		Pomey.
Purpure,		Golpe.

Crescent, or half-moon, having its horns turned upwards.

Increscent, differs from the crescent, by having its horns turned to the dexter side.

Decrescent, is the reverse of the increscent, having its horns turned to the sinister side.

Rose, is represented, in heraldry, full-blown, with fine green barbs, and seeded in the middle.

Annulet, or ring, and by some authors supposed to be rings of mail.

Chess-rook. This piece is used in the game of chess.

Star, in heraldry, is termed an estoile, having six waved points.

Trefoil, or three-leaved grass.

Quartrefoil, or four-leaved grass.

Cinquefoil, or five-leaved grass.

Mascle, is in shape like the lozenge, but is always perforated, as the example.

Fountain, an heraldic term for a roundle barry wavy of six argents and azure.

Billet, a small parallelogram, supposed to be letters made up in the form of the example.

Rustre, is a lozenge pierced round in the middle.

Gutte, in heraldry, signifies drops of any thing liquid, and, according to their colour, are termed as follow: if

Or,	Gutte d'or.
Agent,	Gutte d'eau.
Vert,	Gutte de olive.
Gules,	Gutte de sang.
Azure,	Gutte de larmes.
Sable,	Gutte poix.

Fess, an ordinary composed of two horizontal lines drawn across the centre of the shield.

Chevron, an ordinary, in form like two rafters of a house, or a pair of compasses extended.

Bend, an ordinary, drawn diagonally from the dexter chief to the sinister base, and takes up one-third of the field.

Pale, an ordinary, which is placed perpendicular in the centre of the shield.

Chief, an ordinary, which always occupies the upper part of the shield, and contains in depth the third of the field.

Cross, an ordinary, composed of four lines, four perpendicular, and two transverse.

Saltire, an ordinary, in form like the cross of St. Andrew.

Bend-sinister, which is placed diagonally from the sinister chief to the dexter base of the shield.

Quarter, an ordinary, formed of two lines, one perpendicular, the other horizontal, taking up one-fourth of the field, as the example.

Canton, an ordinary in form like the quarter, but the size is only the third part of the chief.

Pile, an ordinary, like the foot of the pile that is driven into the ground to make the foundation of a building in swampy ground.

Flanches, are composed of two circular lines, and are always borne double, as the example.

Flory, a cross, the ends terminating in fleurs-de-lis.

Moline, a cross, which turns round both ways at the extremities, like a hook.

Pattee, a cross, small in the centre, and widening to the ends, which are very broad.

Croslet, a cross, crossed again at the extremities at a small distance from each of the ends.

Lozenge, a four-cornered figure, like a pane of glass in old casements, supposed to be a physical composition given for colds, and was invented to distinguish eminent physicians.

Mullet, consists of five points, and pierced in the centre, and is supposed to represent a spur rowel.

Mill-rind, a cross in form like the mill-ink which carries the millstone, and is perforated in the centre.

Water-boujet, anciently used as a vessel by soldiers for carrying water in long marches.

Helmets, were formerly worn as a defensive weapon to cover the bearer's head: a helmet is now placed over a coat of arms as its chief ornament, and a mark of gentility. The

First is a side-faced helmet of steel, with the vizor shut, for an esquire.

Second is a full-faced helmet of steel, with the vizor open, for knights or baronets.

Third is a side-faced helmet of steel, the bars and ornaments gold, for the nobility.

Fourth is a full-faced helmet, with bars all gold, for the sovereign and princes of the blood royal.

Close, signifies the wings of a bird are down, and close to the body.

Rising. This term is for a bird when in a position as if preparing to fly.

Displayed, signifies the wings of an eagle to be expanded, as the example.

Volant, a term for any bird represented flying.

Tripping, a term for a stag, antelope, or hind, when walking.

Courant, for a stag, or horse, or greyhound, running.

At gaze, is a term for a stag or hind; when looking full-faced, is termed at gaze.

Lodged, signifies the stag to be at rest on the ground.

Inverted, is for two wings conjoined, and the points of the wings downwards.

Erect, is for two wings conjoined, and the points erect, or upwards.

Hauriant. This term is for a fish when erect, paleways, as putting its head above water.

Naiant, for a fish, when borne horizontally across the shield, as swimming.

Cockatrice, a chimerical figure used in heraldry; its beak, wings, legs, comb, wattles, and spurs, partake of the fowl; and its body and tail of the snake.

Wyvern. This, like the former, is chimerical, and differs from the cockatrice in its head, having no comb, wattles, or spurs.

Dragon. This is an heraldic figure, as drawn by heralds. See the example.

Tiger. This, like the former, is of heraldic crea-

tion; being so different from the tiger of nature, it is termed the heraldic tiger.

Checky, is a shield or bearing, covered with small squares of different colours alternately.

Gyronny, is a shield divided into six or eight triangular parts of different colours, and the points all meeting in the centre of the shield.

Paly, is a shield divided into four, six, or more equal parts, by perpendicular lines, consisting of two colours.

Barry, is a shield divided into four, six, or more equal parts, by horizontal lines of two colours.

Bachelor.—The arms of a bachelor, whilst he remains such, he may quarter his paternal coat with other coats, if they belong to him, but he may not impale it till he is married.

Married man.—A married man is to conjoin the coat armours of himself and wife in one escutcheon paleways; the man's on the dexter side of the shield, and the woman's on the sinister side.

An heiress.—When an heiress is married, her arms are not to be impaled with her husband's, but are to be borne on an escutcheon of pretence, placed in the centre of the shield. Note, the escutcheon of pretence displays his pretension to her estate; and if the husband has issue by her, the heir of those two inheritors shall bear the hereditary coats of father and mother quarterly.

Quarterly.—Is an arms divided into four parts by a perpendicular and horizontal line crossing each other, in the centre of the shield, into four equal parts, termed quarters.

Maid.—The arms of a maid are to be placed in a lozenge; and if her father bore any difference in his coat the same is to be continued; for by the mark of cadency of her father's will be denoted what branch she is from.

Widow.—The arms of a widow are to be impaled with the arms of her late husband; her husband on the dexter side, and her's on the sinister side, upon a lozenge, as the example.

Knight of the garter and his lady.—When a knight of the garter is married, his wife's arms must be placed in a distinct shield, because his arms are surrounded with the ensign of that order: for though the husband may give his equal share of the shield and hereditary honour, yet he cannot share his temporary order of knighthood with her.

Commoner and his lady.—The arms of a commoner married to a lady of quality: he is not to impale her arms with his own; they are to be set aside of one another in separate shields, as the lady still retains her title and rank. See the example.

Of the external ornaments of escutcheons.—The ornaments that accompany or surround escutcheons denote the birth, dignity or office, of the person to whom the coat of arms appertaineth; and obtains both among the laity and clergy. The chief of which are as follow:

Crowns.—The first crowns were only diadems, bands, or fillets; afterwards they were composed of branches of divers trees, and then flowers were added to them. Among the Greeks, the crowns given to those who carried the prize at the Isthmian games, were of pine; at the Olympic, of laurel; and at the Nemean, of smallage. The Romans had various crowns to reward martial exploits and extraordinary services done to the republic. Examples of some of these crowns are frequently met with i modern achievements.

Modern crowns are only used as an ornament, which emperors, kings, and independent princes set on their heads, in great solemnities, to denote their sovereign authority. These are described in heraldry as follow:

The imperial crown is made of a circle of gold, adorned with precious stones and pearls, heightened with fleurs-de-lis, bordered and seeded with pearls, raised in the form of a cap voided at the top, like a crescent. From the middle of this cap rises an arched fillet enriched with pearls, and surmounted of a mound, whereon is a cross of pearls. See Plate LXVI.

The crown of the kings of Great Britain is a circle of gold, bordered with ermine, enriched with pearls and precious stones, and heightened up with four crosses pattee, and four large fleurs-de-lis alternately; from these rise four arched diadems adorned with pearls which close under a mound, surmounted of a cross like those at bottom.

The crowns of Spain and Portugal are a ducal coronet, heightened up with eight arched diadems that support a mound, ensigned with a plain cross. Those of Denmark and Sweden are both of the same form; and consist of eight arched diadems, rising from a marquis's coronet, which conjoin at the top under a mound ensigned with a cross botone. The crowns of most other kings in Europe are circles of gold, adorned with precious stones, and heightened up with large trefoils and closed by four, six, or eight diadems supporting a mound, surmounted of a cross.

The great Turk bears over his arms a turban, enriched with pearls and diamonds, under two coronets, the first of which is made of pyramidical points heightened up with large pearls, and the uppermost is surmounted with crescents.

The pope appropriates to himself a tiara or long cap of golden cloth: from which hang two pendants embroidered and fringed at the ends, semée of crosses of gold. This cap is inclosed by three marquis's coronets; and has on its top a mound of gold, whereon is a cross of the same, which cross is sometimes represented by engravers and painters pometted, recrossed, flowery, or plain. It is a difficult matter to ascertain the time when these haughty prelates assumed the three forementioned coronets. See Plate LXVI.

Coronets.—The coronet of the prince of Wales, or eldest son of the king of Great Britain, was anciently a circle of gold set round with four crosses-pattee, and as many fleurs-de-lis alternately; but since the restoration it has been closed with one arch only, adorned with pearls, and surmounted of a mound and cross, and bordered with ermine like the king's. But beside the coronet his royal highness has another distinguishing mark of honour, peculiar to himself, viz. a plume of three ostrich feathers, with an ancient coronet of a prince of Wales. Under it, in a scroll, is this motto, Ich dien, which in the German or old Saxon language signifies "I serve." The device was at first taken by Edward prince of Wales, commonly called the black prince, after the famous battle of Cressy, in 1346, where having with his own hand killed John, king of Bohemia, he took from his head such a plume, and put it on his own. See Plate LXV.

The coronet of all the immediate sons and brothers of the kings of Great Britain is a circle of gold, bordered with ermine, heightened up with four fleurs-de-lis, and as many crosses-pattee alternate. The particular and distinguishing form of such coronets as are appropriated to princes of the blood royal, is described and settled in a grant of Charles II. the 13th of his reign. See Plate LXV.

The coronet of the princesses of Great Britain is a circle of gold, bordered with ermine, and heightened up with crosses-pattee, fleurs-de-lis, and strawberry leaves alternate; whereas a prince's coronet has only fleurs-de-lis and crosses.

A duke's coronet is a circle of gold bordered with ermine, enriched with precious stones and pearls, and set round with eight large strawberry or parsley leaves. See Plate LXV.

A marquis's coronet is a circle of gold, bordered with ermine, set round with four strawberry leaves, and as many pearls on pyramidical points of equal height, alternately. See Plate LXV.

An earl's coronet is a circle of gold, bordered with ermine, heightened up with eight pyramidical points or rays, on the tops of which are as many large pearls, that are placed alternately with as many strawberry leaves, but the pearls much higher than the leaves. See Plate I.

A viscount's coronet differs from the preceding ones as being only a circle of gold bordered with ermine, with large pearls set close together on the rim, without any limited number, which is his prerogative above the baron, who is limited. See Plate LXV.

A baron's coronet, which it appears was granted by king Charles II., is formed with six pearls set at equal distances on a gold circle, bordered with ermine, four of which only are seen on engravings, paintings, &c. to show he is inferior to the viscount. See Plate LXV.

The eldest sons of peers, above the degree of a baron, bear their father's arms and supporters with a label, and use the coronet appertaining to their father's second title; and all the younger sons bear their arms with proper differences, but use no coronets.

As the crown of the king of Great Britain is not quite like that of other potentates, so do most of the coronets of foreign noblemen differ a little from those of the British nobility.

Mitres.—The archbishops and bishops of England and Ireland place a mitre over their coat of arms. It is a round cap pointed and cleft at the top, from which hang two pendants fringed at both ends; with this difference, that the bishop's mitre is only surrounded with a fillet of gold, set with precious stones, whereas the archbishops's issues out of a ducal coronet. See Plate LXV.

This ornament, with other ecclesiastical garments, is still worn by all the archbishops and bishops of the church of Rome, whenever they officiate with solemnity; but it is never used in England otherwise than on coats of arms, as before mentioned.

The first archbishop's consecration in England was in the year 568. No mitre but an archbishop's is borne upon a ducal coronet, except the bishop of Durham, that see being a principality.

The first bishop's consecration in England was in the year 516.

Chapeaux, wreaths, and crests.—A chapeau is an ancient hat, or rather cap, of dignity, worn by dukes, generally scarlet-coloured velvet on the outside, lined and turned up with fur; frequently to be met with above an helmet, instead of a wreath, under gentlemen's and noblemen's crests. Heretofore they were seldom to be found, as of right appertaining to primate families; but by the grants of Robert Cooke, Clarencieux, and other succeeding heralds, these, together with ducal coronets, are now frequently to be met with in families, who yet claim not above the degree of gentlemen. See Plate LXVI.

The wreath is a kind of roll made of two skains of silk of different colours twisted together, which ancient knights wore as a headdress when equipped for tournaments. The colours of the silk are always taken from the principal metal and colour contained in the coat of arms of the bearer. They are still accounted as one of the lesser ornaments of ecutcheons, and are placed between the helmet and the crest (see Plate LXVI). In the time of Henry I. and long after, no man who was under the degree of a knight had his crest set on a wreath; but this, like other prerogatives, has been infringed so far that every body now-a-days wears a wreath.

The crest is the highest part of the ornaments of a coat of arms. It is called crest, from the Latin word crista, which signifies comb or tuft, such as many birds have upon their heads, as the peacock, pheasant, &c. in allusion to the place on which it is fixed. See Plate LXVI. crest of the prince of Wales.

Crests were formerly great marks of honour, because they were only worn by heroes of great valour, or by such as were advanced to some superior military command, in order that they might be the better distinguished in an engagement, and thereby rally their men if dispersed; but they are at present considered as a mere ornament. The crest is frequently a part either of the supporters, or of the charge borne in the escutcheon. Thus the crest of the royal achievement of Great Britain is a "lion guardant crown'd." See Pl. LXVI. There are seral instances of crests that are relative to alliance, employments, or names; and which on that account have been changed.

The scroll and supporters.—The scroll is the ornament usually placed below the crest, containing a motto, or short sentence, alluding thereto, or to the bearings, or to the bearer's name, as in the two following instances. The motto of the noble earl of Cholmondeley is, "Cassis tutisima virtus;" *i. e.* "Virtue is the safest helmet;" on account of the helmet in the coat of arms. The motto of the right hon. lord Fortescue is, "Forte scutum salus ducum;" *i. e.* "A strong shield is the safety of the commanders;" alluding to the name of that ancient family. Sometimes it has reference to neither, but expresses something divine or heroic; as that of the earl of Scarborough, which is. "Murus æreus conscientia sana;" *i. e.* "A good conscience is a wall of brass." Others are enigmatical; as that of the royal achievement, which is, "Dieu et mon droit;" *i. e.* "God and my right;" introduced by Edward III. in 1340, when he assumed the arms and title of king of France, and began to prosecute his claim, which occasioned long and bloody wars, fatal, by turns, to both kingdoms. Mottos, though hereditary in the families that first took them up, have been changed on some particular occasions, and others

appropriated in their stead, instances of which are sometimes met with in the history of families.

Supporters are figures standing on a scroll, and placed at the side of the escutcheon; they are so called because they seem to support or hold up the shield. Supporters have formerly been taken from such animals or birds as are borne in the shields, and sometimes they have been chosen as bearing some allusion to the names of those whose arms they are made to support. The supporters of the arms of Great Britain, since king James the First's accession to the throne, are, a lion rampant guardant crowned or, on the dexter side, and an unicorn argent, crowned, armed, unguled, maned and gorged with an antique crown, to which a chain is affixed, all or, on the sinister. See Plate LXXI.

It is to be observed, that bearing coats of arms supported, is, according to the heraldic rules of England, the prerogative, 1st, Of those called nobiles majores, viz. dukes, marquisses, earls, viscounts, and barons; 2d, Of all knights of the garter, though they should be under the degree of barons; 3d, Of knights of the Bath, who both receive on their creation a grant of supporters; and, lastly, of such knights as the king chooses to bestow this honour upon.

Of the laws of heraldry, and the method of marshalling coats of arms.—1. The first and most general rule is, to express heraldic distinctions in proper terms, so as not to omit any thing that ought to be specified, and at the same time to be clear and concise without tautology. 2. Begin with the tincture of the field, and then proceed to the principal charges which possesses the most honourable place in the shield, such as fess, cheveron, &c. always naming that charge first which lies next and immediately upon the field. 3. After namning the tincture of the field, the honourable ordinaries, or other principal figures, you must specify their attributes, and afterwards their metal or colour. 4. When an honourable ordinary, or some one figure, is placed upon another, whether it be a fess, cheveron, cross, &c. it is always to be named after the ordinary or figure over which it is placed, with one of these expressions, surtout, or over all. 5. In the blazoning of such ordinaries as are plain, the bare mention of them is sufficient; but if an ordinary should be made of any of the crooked lines mentioned above, its form must be specified; that is, whether it be engrailed, wavy, &c. 6. When a principal figure possesses the centre of the field, its position is not to be expressed, or (which amounts to the same thing) when a bearing is named, without specifying the point where it is placed, then it is understood to possess the middle of the shield. 7. The number of the points of mullets or stars must be specified when more than five; and also if a mullet or any other charge be pierced, it must be mentioned as such, to distinguish it from what is plain. 8. When a ray of the sun, or other single figure, is borne in any other part of the escutcheon than the centre, the point it issues from must be named. 9. The natural colour of trees, plants, fruits, birds, &c. is no otherwise to be expressed in blazoning but by the word proper; but if discoloured, that is, if they differ from their natural colour, it must be particularized. 10. When three figures are in a field, and their position is not mentioned in the blazoning, they are always understood to be placed two above, and one below. 11. When there are many figures of the same species borne in a coat of arms, their number must be observed as they stand, and must be distinctly expressed.

By marshalling coats of arms is to be understood the art of disposing divers of them in one escutcheon, and of distributing their contingent ornaments in proper places. Various causes may occasion arms to be thus conjoined, which are comprised under two heads, viz. manifest and obscure. What is meant by manifest causes in the marshalling of coats of arms, are such as betoken marriages, or a sovereign's gift, granted either through the special favour of the prince, or for some eminent services. Concerning marriages it is to be observed,

1. when the coats of arms of a married couple, descended of distinct families, are to be put together in one escutcheon, the field of their respective arms is conjoined paleways, and blazoned parted per bale, baron and femme, two coats; first, &c. In which case the baron's arms are always to be placed on the dexter side, and the femme's arms on the sinister side.

2. If a widower marry again, his late and present wife's arms are, "to be placed on the sinister side, in the escutcheon with his own, and parted per pale. The first wife's coat shall stand on the chief, and the second on the base; or he may set them both in pale with his own, the first wife's coat next to himself, and his second outermost. If he should marry a third wife, then the two first matches shall stand on the chief, and the third shall have the whole base. And if he take a fourth wife, she must participate one-half of the base with the third wife, and so will they seem to be so many coats quartered." But it must be observed that these forms of impalring are meant of hereditary coats, whereby the husband stands in expectation of having the hereditary possession of his wife united to his patrimony. Note. If a man marry a widow, he marshals her maiden arms only.

3. In the arms of femmes joined to the paternal coat of the baron, the proper differences by which they were borne by the fathers of such women must be inserted.

4. If a coat of arms that has a bordure be impaled with another, as by marriage, then the bordure must be wholly omitted in the side of the arms next the centre.

5. The person that marries an heiress, instead of impailing his arms with those of his wife, is to bear them in an escutcheon placed in the centre of his shield, which, on account of its showing forth his pretension to her estate, is called an excutcheon of pretence, and is blazoned surtout, that is, over-all. But the children are to bear the hereditary coat of arms of their father and mother quarterly, which denotes a fixed inheritance, and so transmit them to posterity. The first and fourth quarters generally contain the father's arms, and the second and third the mother's; except the heirs should derive not only their estate, but also their title and dignity, from their mother.

6. If a maiden or dowager lady of quality marry a commoner, or a nobleman inferior to her in rank, their coats of arms may be set beside one another, in two separate escutcheons, upon one mantle or drapery, and the lady's arms ornamented according to her title. See Plate LXVI.

7. Archbishops and bishops impale their arms differently from the fore-mentioned coats, in giving the place of

honour, that is, the dexter side, to the arms of their dignity, as it is expressed in Plate LXV. which represents the coat of arms of a supposed archbishop of Canterbury and bishop of an English see.

With respect to such armorial ensigns as the sovereign thinks fit to augment a coat of arms with, they may be marshalled in various ways, as may be seen in the arms of his grace the duke of Rutland, and many others.

So far the causes for marshalling divers arms in one shield, &c. are manifest. As to such as are called obscure, that is, when coats of arms are marshalled in such a manner that no probable reason can be given why they are so conjoined, the explanation of them must be left to the heralds.

Of the orders of knighthood, &c.—The baronet's mark of distinction, or the arms of the province of Ulster in Ireland, granted and made hereditary in the male line by king James I. who erected this dignity on the 22d of May, 1611, in the 9th year of his reign, in order to propagate a plantation in the forementioned province. This mark is argent, a sinister hand couped at the wrist and erected gules; which may be borne either in a canton, or in an escutcheon, as will best suit the figures of the arms. The ancient and respectable badge of the most noble order of the garter, was instituted by king Edward III. 1349, in the 27th year of his reign. This honourable augmentation is a deep blue garter, surrounding the arms of such knights, and inscribed with this motto, "Honi soit qui mal y pense." See plate LXVI.

The arms of those who are knights of the orders of the Bath, of the Thistle, or of St. Patrick, are marshalled in the same manner, with this difference only, that the colour and motto accord with the order to which it belongs. Thus the motto, "Quis separabit 1783," on the light blue ribbon of the order, surrounds the escutcheon of a knight of St. Patrick. "Nemo me impune lacessit," on a green ribband, distinguishes a knight of the Thistle; and "Tria juncta in uno," on red, a knight of the Bath. It is to be observed that none of the orders of knighthood are hereditary. The honours of a baronet of Ulster, and of a baronet of Nova Scotia (created by patent in 1602), descend to the heirs male.

With regard to the emblazoning of the wife's arms in the case of the husband being noble; or where, on the other hand, the wife is noble in her own right, and the husband a commoner, these will be found exemplified in Plate LXVI.

For representations of the badges of the several orders of knighthood, see Plate LXVI. See ARMS, BLAZONING, PRECEDENCY, and the several terms of heraldry in alphabetical order.

HERBAL, is sometimes used for what is more usually called hortus siccus. See HORTUS SICCUS.

HERCULES, in astronomy, a constellation of the northern hemisphere, said to contain from 28 to 95 stars.

HEREDITAMENTS, all such things immoveable, whether corporeal or incorporeal, as a man may leave to his heirs, by way of inheritance; or not being otherwise devised, do naturally descend to him who is next heir of blood, and fall not within the compass of an executor or administrator, as chattles do. It is a word of large extent, and much used in conveyances; for by the grant of hereditaments, isles, seignories, manors, houses, and lands of all sorts, charters, rents, services, advowsons, commons, and whatever may be inherited, will pass. Co. Lit. 6.

Hereditaments are of two kinds, corporeal and incorporeal. Corporeal hereditaments consist wholly of substantial and permanent objects, all which may be comprehended under the general denomination of land only: for land comprehends in its legal signification any ground, soil, or earth whatsoever, as arable, meadows, pastures, woods, moors, waters, marshes, furzes, and heath. 1 Inst. 4.

Incorporeal hereditaments are not the objects of sensation, neither can they be seen or handled, are creatures of the mind, and exist only in contemplation: they are principally of ten sorts, viz. advowsons, tithes, commons, ways, offices, dignities, franchises, corodies or presents, and rents. Black.

HERESEY, among protestants, is said to be a false opinion, repugnant to some point of doctrine clearly revealed in scripture, and either absolutely essential to the christian faith, or at least of most high importance. 1 Haw. 3.

All old statutes that give a power to arrest or imprison persons for heresey, or introduced any forfeiture on that account, are repealed; yet by the common law an obstinate heretic being excommunicated is still liable to be imprisoned by force of the writ, de excommunicato capiendo, till he makes satisfaction to the church. 1 Haw. 5.

And if any person having been educated in, or having made profession of the christian religion within this realm, shall be convicted in any of the courts at Westminster, or at the assizes, of denying any of the persons in the Holy Trinity to be God, or maintaining that there are more gods than one, or of denying the truth of the christian religion, or the divine authority of the holy scriptures, he shall, for the first offence, be adjudged incapable of any office; and for the second shall be disabled to sue any action, or to be guardian, executor, or administrator, or take by any legacy or deed of gift, or to bear any office civil or military, or benefice ecclesiastical, for ever, and shall also suffer imprisonment for three years, without bail or mainprise, from the time of such conviction.

HERIOT, signifies a tribute given to the lord for his better preparation towards war. And by the laws of Canute it appears, that at the death of the great men of his nation so many horses and arms were to be paid for as they were in the their respective lifetimes obliged to keep for the king's service.

A heriot was first paid in arms and horses; it is now by custom sometimes the best live beast which the tenant dies possessed of; sometimes the best inanimate good, under which a jewel or piece of plate may be included. 2 Black. 422.

As to the several kinds of heriots, some are due by custom, some by tenure, and by reservation on deeds executed within time of memory; those due by custom are the most frequent, and arose by the contract or agreement of the lord and tenant, in consideration of some benefit or advantage accruing to the tenant, and for which an heriot, as the best beast, best piece of household fur-

niture, &c. became due, and belonged to the lord either on the death or alienation of the tenant, and which the lord may seize, either within the manor or without, at his election. Dyer, 199, b.

It has been solemnly adjudged that for an heriot service, or for an heriot reserved by way of tenure, the lord may either seize or distrain; for when the tenant agrees that the lord shall on his death have the best beast, &c. the lord has his election which beast he will take, and by seizing thereof reduces that to his possession, wherein he had a property at the death of the tenant, without the concurring act of any other person; and it is not like the case where the tenant receives 20*s.* or a robe, for there the lessee has his election which he will pay, and being to do the first act, the lord cannot seize, but must distrain. Plowd. 96.

If the tenure be by rent and heriot service, viz. to have the best beast after the death of the tenant, and the lord distrain for the heriot, he cannot in his avowry show which was the best beast that he was entitled to, nor of what value it was; for the tenant might have esloined the cattle, and thereby it might have been impossible for the lord to know which was the best beast; and the tenant at his peril is to render the best beast, or sufficient recompense. Cro. Car. 260.

Upon the whole, the custom of the manor is the law of it in all such like cases.

HERISSON, in fortification, a beam armed with a great number of iron spikes, with their points outwards, and supported by a pivot, on which it turns. These serve as a barrier to block up any passage, and are frequently placed before the gates, and more especially the wicket-doors of a town or fortress, to secure those passages which must of necessity be often opened and shut. See FORTIFICATION.

HERITIERA, a genus of the monœcia monadelphia class and order. The calyx is five-toothed; corolla none. Male, anthers 10, without filaments. Female, germ five; drupes with one globular seed. There is one species, a tree of the East Indies.

HERMÆA, in antiquity, ancient Greek festivals, in honour of the god Hermes, or Mercury.

HERMANNIA, a genus of the pentandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The capsule is quinquelocular; the petals at the base are semi-tubulated and oblique. There are 21 species, the most remarkable are,

1. The lavendulifolia, which has a shrubby stalk and slender branches, very bushy, about a foot and a half high, small, spear-shaped, obtuse, and hairy leaves, with clusters of small yellow flowers along the sides of the branches, continuing from June to autumn.

2. The althæifolia has a shrubby stalk, and soft woolly branches, growing two feet high, with numerous yellow flowers in loose spikes growing at the end of the branches, and making their appearance in July.

3. The grossularifolia has a shrubby stalk and spreading branches, growing three or four feet high, with bright yellow flowers coming out in great numbers at the ends of all the shoots and branches in April or May.

4. The alnifolia has a shrubby stalk, and branches gorwing irregularly four or five feet high, with pale yellow flowers in short spikes from the sides and ends of the branches, appearing in April or May.

5. The hyssopifolia has a shrubby upright stalk, branching out laterally six or seven feet high, with pale yellow flowers in clusters from the sides of the branches, appearing in May and June. All these plants are natives of Africa, and therefore must be kept in a greenhouse during the winter in this country. They are propagated by cuttings of their young shoots, which may be planted in pots of rich earth any time from April to July.

HERMAS, a genus of the monœcia order, in the polygamia class of plants. The umbel in the hermaphrodite is terminal; there is an universal involucrum, and partial ones. The rays of the small umbels are lobed; the central one flower-bearing; there are five petals, and as many barren stamina; the seeds are two-fold, and suborbicular. In the male the lateral umbels have universal and partial involucra; the small umbels are many-flowered; there are five petals, and five fertile stamina. There are five species, herbs of the Cape.

HERMETICAL SEAL, among chemists, a method of stopping glass-vessels, used in chemical operations, so closely, that the most subtile spirit cannot escape through them. It is commonly done by heating the neck of the vessel in a flame, till ready to melt, and then twisting it close together with a pair of pincers. Or, vessels may be hermetically sealed, by stopping them with a glass plug, well luted; or by covering the vessel with another ovum philosophicum.

HERNANDIA, *jack-in-a-box-tree,* a genus of the triandria order, belonging to the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. The male calyx is tripartite; the corolla tripetalous; the female calyx is truncated, quite entire; the corolla hexapetalous; the plum hollow, and open at the mouth or upper part, with a loose kernel. The species are,

1. The sonora, or common jack-in-a-box, a native of both the Indies. It grows 20 or 30 feet high, with broad peltated leaves, and monœcious flowers, succeeded by a large swoollen hollow fruit formed of the calyx; having a hole or opening at the end, and a hard nut within. The wind blowing into the cavity of this fruit makes a very whistling and rattling noise, whence comes the name.

2. The ovigera grows many feet high, with large oval leaves not peltated; and monœcious flowers, succeeded by a swoollen fruit open at the end, and a nut within. It is said the sonora in Java affords a sure antidote against poison, if you either put its small roots on the wounds, or eat them; as was discovered to Rumphus by a captive woman in the war between the people of Macassar and the Dutch, in the year 1667. The soldiers of the former always carry this root about them, as a remedy against wounds with poisoned arrows. Both these plants being tender exotics, must be planted in pots of rich earth, and always kept in a hot-house; in which, notwithstanding all the care that can be taken, they seldom flower, and never grow beyond the height of common shrubs, though in the places where they are natives they arrive at the height of trees. They are propagated by seeds procured from the West Indies.

HERNIA. See MEDICINE and SURGERY.

HERNIARIA, *rupture-wort*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the eleventh order, holoraceæ. The calyx is quinquepartite; there is no corolla; there are five barren stamina, and a monospermous capsule. There are four species, of which the only remarkable one is the glabra, or smooth rupture-wort, a native of many parts of England. It is a low trailing plant, with leaves like the smaller chickweed; the flowers come out in clusters from the side of the stalks at the joints, and are of a yellowish green colour. This plant is a little saltish and astringent. The juice is useful to take away specks in the eye. Cows, sheep, and horses, eat the plant; goats and swine refuse it.

HERON, in ornithology. See Ardea.

HERRING, in ichthyology. See Clupea and Fishery.

HERRINGS. It is unlawful to buy or sell herrings at sea before the fishermen come into the haven, and the cable of the ship be drawn to the land. 31 Ed. III. c. 2.

No herring shall be sold in any vessel but where the barrel contains 32 gallons, and half barrel and firkin accordingly; and they must be well packed, of one time's packing and salting, and be as good in the middle as at the ends; on pain of forfeiting 3*s.* 4*d.* a barrel.

Vessels with herrings are to be marked with the quantity and place where packed; and packers are to be appointed and sworn in all fishing ports, and under the penalty of 100*l.*

HERSE, in fortification, is a lattice or portcullice, made in the form of a harrow, and stuck full of iron spikes. See Fortification.

HESPERIS, *dame's violet*, or *queen's gilliflower*, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. The petals are turned obliquely; there is a glandule within the shorter stamina; the siliqua almost upright; the stigma forked at the base, connivent, or closing at the top. There are seven species, the most remarkable are,

1. The matronalis, or common sweet-scented garden rocket, having fibrous roots, crowned with a tuft of long, spear-shaped, rough, leaves; upright, single, hairy stalks, two feet high, terminated by large and long spikes of sweet-scented flowers of different colours and properties in the varieties, of which there is a great number. All the varieties of this species are so remarkable for imparting a fragrant odour, that the ladies were fond of having them in their apartments. Hence they derived the name of dame's violet; and bearing some resemblance to a stock-gilliflower were sometimes called queen's gilliflower, but are now most commonly called rocket.

2. The inodora, or scentless rocket, has upright stalks two feet high, all the branches terminated by large spikes of scentless flowers, with obtuse petals, of different colours and properties in the varieties.

3. The tristis, or dull-flowered night-smelling rocket, has upright, bristly stalks, two feet high, spear-shaped pointed leaves, and spikes of pale purple flowers, of great fragrance in the evening.

All the species are hardy, especially the first and second, which prosper in any of the open borders, and any common garden soil; but the third, being rather impatient of a severe frost, and of much moisture in winter, should have a dry warm situation, and a few may be placed in pots, to be sheltered in case of inclement weather. They may be propagated either by seeds, by offsets, or by cuttings off the stalks.

HESSIAN Fly. See Tenthredo.

HETEROGENEOUS Numbers, mixed numbers, consisting of integers and fractions.

Heterogeneous Quantities, are those which are of such different kinds, as that one of them taken any number of times, never equals or exceeds the other.

Heterogeneous Surds, are such as have different radical signs, as $\sqrt[2]{aa}$, $\sqrt[5]{bb}$, $\sqrt[3]{9}$, $\sqrt[7]{18}$, &c. See Surd.

If the indices of the powers of the heterogeneous surds be divided by their greatest common divisor, and the quotients be set under the dividends; and those indices be multiplied crosswise by each others quotients; and before the products be set the common radical sign $\sqrt{}$, with its proper index; and if the powers of the given roots be involved alternately, according to the index of each others quotient, and the common radical sign be prefixed before those products, then will those two surds be reduced to others, having but one common radical sign. As to reduce

$$\sqrt[2]{aa} \text{ and } \sqrt[4]{bb}$$
$$2)\sqrt{aa}\ (2 \quad \sqrt[4]{bb} \quad \begin{matrix} 1 \times 2 \\ \sqrt[4]{bb} \end{matrix} \quad \sqrt[4]{aaaa}$$

HETEROSCII. See Geography.

HETEROUSIANS, a sect of Arians, who did not believe that the Son of God was of a substance like to that of the Father.

HEUCHERA, in botany, a genus of the pentandria digynia class of plants, the corolla whereof consists of five petals; the fruit is an ovato-accuminated capsule; semibifid, terminating in two refex points, and containing two cells. There are two species.

HEXACHORD, in ancient music, a concord called by the moderns a sixth.

HEXAEDRON, or Hexahedron, one of the five regular or Platonic bodies; being indeed the same as the cube; and is so called from its having six faces—The square of the side or edge of a hexahedron, is one-third of the square of the diameter of the circumscribing sphere; and hence the diameter of a sphere is to the side of its inscribed hexahedron, as $\sqrt{3}$ to 1.

In general, if A, B, and C, be put to denote respectively the linear side, the surface and the solidity of a Hexahedron, or cube, also, the radius of the inscribed sphere, and R the radius of the circumscribed one; then we have these general equations or relations:

1. $A = 2r = \frac{2}{3}R\sqrt{3} = \sqrt{\frac{1}{6}B} = \sqrt[3]{C}$.
2. $B = 24\sqrt{} = 8R^2 = 6A^2 = 6\sqrt[3]{r^2}C^2$.
3. $C = 8r^3 = \frac{8}{9}R^3\sqrt{3} = A^3 = \frac{1}{6}B\sqrt{\frac{1}{6}B}$.
4. $R = r\sqrt{3} = \frac{1}{2}A\sqrt{3} = \frac{1}{2}\sqrt{\frac{1}{2}B} = \frac{1}{2}\sqrt{3} \times \sqrt[3]{C}$.
5. $r = \frac{1}{2}R\sqrt{3} = \frac{1}{2}A = \frac{1}{2}\sqrt{\frac{1}{6}B} = \frac{1}{2}\sqrt[3]{C}$.

HEXAGON, in geometry, a figure of six sides and angles; and if these sides and angles be equal, it is called a regular hexagon.

The side of every regular hexagon, inscribed in a circle, is equal in length to the radius of that circle. Hence, it is easy, by laying off the radius six times upon the circumference, to inscribe an hexagon in a circle.

To describe a regular hexagon on a given right line AB, (plate LXXII. Miscel. fig. 123,) draw an equilateral triangle ACB, and the vertex C will be the centre of a circle which will circumscribe the hexagon required ABDEFG.

As 1 is to 1 672, so is the square of the side of any regular hexagon to the area thereof, nearly. Or the side of a hexadon being s, its area will be $= 2.598076 2s^2 = \frac{3}{2}s^2 \times \text{tang. } 60^{\circ} = \frac{3}{2}s^2\sqrt{3}$.

HEXAGON, in fortification, is a place defended by six bastions.

HEXAMETER, in ancient poetry, a kind of verse, consisting of six feet; the first four of which may be indifferently, either spondees or dactyls; the fifth is generally a dactyl and the sixth always a spondee. Such is the following verse of Horace:

1 2 3 4 5 6

Aut pro | desse vo | lunt, aut | delec | tura po | etæ.

HEXANDRIA, in botany, a class of plants, the sixth in order, comprehending all those plants which have hermaphrodite flowers, and six stamina in each.

HIBISCUS. *Syrian mallow*, a genus of the polyandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is double, the exterior one polyphyllous, the capsule quinquelocular and polyspermous. Of this genus there are 45 species; the most remarkable of which are,

1. The Syriacus, commonly called althæa frutex.

2. The rosa sinensis, with an arborescent stem, and egg-pointed as wed leaves. It is a native of the East Indies, whence it has obtained the name of China rose; but the seeds having been carried by the French to their West India settlements, it has thence obtained the name of Martinico rose. Of this there are the double and single flowering kinds; the seeds of the first frequently produce plants that have only single flowers, but the latter seldom vary to the double kind.

3. The mutabilis, or changeable rose, has a soft spongy stem, which by age becomes ligneous and pithy. It rises to the height of 12 or 14 feet, with heart-shaped leaves. The flowers are produced from the wings of the leaves; the single are composed of five petals, which spread open, and are at first white, but afterwards change to a bluish rose-colour, and as they decay turn purple. In the West Indies all these alterations happen on the same day, and the flowers themselves are of no longer duration; but in Britain the changes are not so sudden.

4. The abelmoschus, or musk-seeded hibiscus, is a native of the West Indies, where the French cultivate great quantities of it. The stalks and leaves of this sort are very hairy. The flowers are large, of a sulphur colour, with purple bottoms; and are succeeded by pyramidal five-corned capsules, which open in five cells, filled with large kidney shaped seeds of a very musky odour.

5. The tiliaceus, or maho-tree, is a native of both the Indies. It rises with a woody, pithy stem, to the height of ten feet, with heart-shaped leaves ending in acute points. The flowers are produced in loose spikes at the end of the branches, and are of a whitish-yellow colour.

6. The trionum, Venice mallow, or flower of an hour, is a native of some parts of Italy, and has long been cultivated in the gardens of this country under the name of bladder ketmia.

7. The esculentus, or eatable hibiscus, rises to five or six feet; has broad five-parted leaves, and large yellow flowers. The pod or okra is from two to six inches long, and one inch diameter. When ripe it opens longitudinally in five different places, and discharges a number of heart-shaped seeds. "These (Dr. Wright informs us) are gathered green, cut into pieces, dried, and sent home as presents, or are boiled in broths or soups for food. It is the chief ingredient in the celebrated pepper-pot of the West Indies, which is no other than a rich olla: the other articles are either flesh meat, or dried fish and capsicum. This dish is very palatable and nourishing. As a medicine, okra is employed in all cases where emollients and lubricants are indicated."

HICKUP, or *hiccough*. See MEDICINE.

HIDE OF LAND, was such a quantity of land as might be ploughed with one plough within the compass of a year, or so much as would maintain a family; some call it 60, some 80, and some 100 acres.

HIERACITES, in church history, christian heretics in the third century, so called from their leader Hierax, a philosopher of Egypt; who taught that Melchisedic was the Holy Ghost, denied the resurrection, and condemned marriage, &c.

HIERACIUM, *hawkweed*, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked, the calyx is imbricated and ovate; the pappus simple and sessile. There are 55 species, of which the most remarkable are,

1. The aurantiacum, commonly called grim the collier, with an upright, single, hairy, and almost leafless stalk, a foot high, terminated by reddish orange-coloured flowers in a corymbus. These flowers have dark oval ash-coloured calyces; whence the name of grim the collier.

2. The pilosella, or mouse-ear, has blossoms red on the outside, and pale-yellow within; the cups set thick with black hairs. The flowers open at eight in the morning, and close about two in the afternoon.

3. The umbellatum grows to the height of three feet, with an erect and firm stalk, terminated with an umbel of yellow flowers.

HIEROGLYPHICS, in antiquity, mystical characters, or symbols, in use among the Egyptians, and that as well in their writings as inscriptions; being the figures of various animals, the parts of human bodies, and mechanical instruments.

The meaning of a few of these hieroglyphics has been preserved by ancient writers. Thus we are told they represented the supreme Deity by a serpent with the head of a hawk. The hawk itself was the hieroglyphic of Osris; the river-horse, of Typhon; the dog, of Mercury; the cat, of the moon, or Diana; the beetle, of a courageous warrior; a new-born child, of the rising sun; and the like.

HIEROGRAMMATISTS, holy registers, were an order of priests among the ancient Egyptians, who presided over learning and religion.

HIGH, in music, an epithet given to any tone or note considerably acute in respect of some other. A word arbitrarily used, and of various meanings, as applied to bass, tenor, or treble voices, or instruments.

HIGHWAY, a public passage for the king's people, whence it is called the king's highway. It seems that anciently there were but four highways in England, which were free and common to all the king's subjects, and through which they might pass without any toll, unless there were a particular consideration for it; all others which we have at this day are supposed to have been made through the grounds of private persons, on writs of ad quod dammum, &c. which being an injury to the owner of the soil, it is said they may prescribe for toll, without any special consideration. 3 Bac. Abr. 54.

There are three kinds of ways, a foot-way, a pack and prime way, which is both a horse and foot-way, and a cart-way, which contains the other two. 1 Inst. 56.

But notwithstanding these distinctions, it seems that any of the said ways, which is common to all the king's subjects, whether it leads directly to a market-town, or only from town to town, may properly be called an highway; and that any such cart-way may be called the king's highway; that a river common to all men may also be called an highway; and that nuisances in any of the said ways are punishable by indictment; otherwise they would not be punished at all: for they are not actionable, unless they cause a special damage to some particular person; because if such action would lie a multiplicity of suits would ensue. 2 Durnf. and East.

But it seems that a way to a parish-church, or to the common field of a town, or to a village which terminates there, may be called a private way, because it belongs not to all the king's subjects, but only to the particular inhabitants of such parish, house, or village, each of which, as it seems, may have an action for a nuisance therein. 1 Haw. 201.

If passengers have used time out of mind, where the roads are bad, to go by outlets on the land adjoining to an highway in the open field, such outlets are parcel of the highway; and therefore if they are sown with corn, and the track foundrous, the king's subjects may go upon the corn. 1 Roll. Ab. 300.

If a way which a man has becomes impassable or very bad, by the owner of the land tearing it up with his carts, by which means it is filled with water; yet he who has the way cannot dig the ground to let out the water, for he has no interest in the soil. But he may bring his action against the owner of the land for spoiling the way. Godb. 52.

When a private way is spoiled by those who have a right to pass thereon, and not through the default of the owner of the land, it seems that they who have the use and benefit of the way ought to repair it, and not the owner of the soil, unless he is bound thereto by custom or special government. 2 Burn. 483.

Repairing highways. It seems agreed that by the common law the general charge of repairing all highways lies on the occupiers of the lands in the parish wherein they are. But it is said that the tenants of the lands adjoining are bound to scour their ditches. 1 Roll. Abr. 39.

Particular persons may be burdened with the general charge of repairing an highway, in two cases: in respect of an inclosure, or by prescription. As where the owner of lands not inclosed, next adjoining to the highway, incloses his lands on both sides thereof; in which case he is bound to make a perfect good way, and shall not be excused for making it as good as it was at the time of the inclosure, if it was then any way defective; because before the inclosure, when the way was bad, the people for their better passage, went over the fields adjoining, out of the common track, a liberty which the inclosure has deprived them of.

And particular persons may be bound to repair an highway by prescription; and it is said that a corporation aggregate may be compelled to do it by force of a general prescription, that it ought and has used to do it, without showing that it used to do so in respect of the tenure of certain lands, or for other consideration; because such a corporation, in judgment of law, never dies, and therefore if it was ever bound to such duty, it must continue to be always so: neither is it any plea that such a corporation has always done it out of charity; for what it has always done, it shall be presumed to have been always bound to do. But it is said that such a general prescription is not sufficient to charge a private person, because no man is bound to do a thing which his ancestors have done, unless it is for some special reason; as having lands descended to him holden by such services, &c. 1 Haw. 202, 203.

It seems certain in all cases whether a private person is bound to repair an highway by inclosure or prescription, that the parish cannot take the advantage of it on the general issue, but must plead it specially; and that, therefore, if to an indictment against the parish for not repairing an highway, they plead not guilty, this shall be intended only that the ways are in repair, but does not go to the right of reparation. 1 Mod. 112.

At common law, it is said that all the county ought to make good the reparations of an highway, where no particular persons are bound to do it, because the whole county have their ease and passage by the said way. Co. Rep. 13.

By the ancient common law villages are to repair their highways, and may be punished for their decay; and if any does injury, or straightens the highway, he is punishable in the king's bench, or before the justices of peace in the court leet, &c. Cromp. Jurisd. 76.

Destroying any public turnpike-gate, or the rails, or fences thereto belonging, subjects the offender to hard labour for three months, and to be publicly whipped. 1 Geo. II. c. 19.

On conviction at the assizes, the offender may be transported for seven years. And on a second offence, or on demolishing any turnpike-house, he shall be guilty of felony, and transported for seven years. But in both these cases the prosecution must be within six months; and on the convict's returning from transportation he shall suffer death. 5 G. II. c. 33.

Every justice of the peace by the statute, upon his own view, or on oath made to him by the surveyor, may make presentment of roads being out of repair; and there

upon like processes shall be issued as upon indictment.

HIGHWAYMEN, are robbers on the highway; for the apprehending and taking of whom a reward of 40*l.* is given by the statute of 4 and 5 Will. and Mar.

HILLIA, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is hexaphyllous; the corolla cleft in six parts, and very long; the berry inferior, bilocular, and polyspermous. There are two species, shrubs of Jamaica.

HIP, or HAW, in the materia medica, is reputed attenuant and diuretic. There is a very pleasant conserve of hips kept in the shops.

HIPPIA, a genus of the polygamia necessaria order, in the syngenesia class of plants. The receptacle is naked; there is no pappus; the seeds are naked, with very broad margins; the calyx is hemispheric, and sub-imbricated; the radios consists of 10 corollulæ, obscure, and rather cleft into three. There are three species, shrubs of the East Indies and the Cape.

HIPPOBOSCA, a genus of insects of the order diptera. The generic character is, mouth furnished with a bivalve, cylindric, obtuse, nutant snout; body depressed; feet furnished with several claws. This is not an extensive genus; the European hippoboscæ, so far as our present entomological information reaches, scarcely affording more than five or six distinct species. Of these the most familiar is the hippobosca equina (see Plate LXVI. Nat. Hist. fig. 225), or horse-fly, so troublesome to those animals, as well as to cattle, during the decline of summer, by its irritating motion (which is performed in various directions with equal facility), and by the pungent pain which its proboscis excites while in the act of suction. In size it varies in different districts, and seems to be largest in the southern climates. It usually, however, measures something more than a quarter of an inch in length, and is of a flattened form, with a rounded abdomen, and moderately broad obtuse wings: its colour is a blackish chesnut, with the thorax speckled with white, and the abdomen marked with obscure variegations of a deeper cast: the skin is of a remarkably strong, or coriaceous nature, since the insect may be pressed strongly between the fingers without being apparently injured. The female of this insect deposits a single egg at distant intervals, and so very large is the egg, as at least to equal, if not in some degree to surpass, the size of the abdomen itself of the parent insect. In reality, however, this seeming egg may be rather considered as a pupa, since it undergoes no farther alteration of form. It continues perfectly inert, and gradually becomes of a brown, and at length of a polished, black colour; and thus commences a genuine or confirmed pupa, which, if opened after a certain period, exhibits the fly in its unadvanced state, and of a white colour. It often lies during the whole winter in this state, the fly emerging in the succeeding summer.

2. Hippobosca avicularia much resembles the preceding species; but is considerably smaller, and of a dull-green colour: it is often observed on the bodies of various birds, which it infests in a very troublesome degree.

3. Hippobosca hirundinis is equal in size to the H. avicularia, and is of a livid-greenish colour, with the abdomen deeply emarginated behind, so as to represent the usual figure of an inverted heart: the wings are of a sharpened or lanceolate form; and the feet, instead of being terminated by two claws only, as in the generality of insects, have six sharp curved divisions. This species is very often observed on the bodies of swallows, swifts, and martins; and may almost always be found in their nests. Its motion, like that of the two preceding kinds, is brisk, but irregular, moving in all directions with equal facility. The egg or pupa of this species is at least as large in proportion to the parent as that of the horse-fly: it gradually changes to a jet-black colour, and the complete fly is usually produced from it in the space of a month.

4. Hippobosca ovina is commonly known by the name of the sheep-tick, and is very frequently found imbedded in the wool of those animals. It is of a reddish-brown colour, and differs from the rest of the genus in being entirely destitute of wings. Its pupa is also a reddish-brown colour, exactly oval, and of a shining surface.

All the hippoboscæ are remarkably tenacious of life, and the H. ovina in particular, which may often be observed in wool that has long been packed into fleeces.

HIPPOCRAMPUS. See SYNGNETHUS.

HIPPOCRATIA, a genus of the monogynia order, in the triandria class of plants, and in the natural meth o ranking with those of which the order is doubtful. The calyx is quinquepartite; the petals five, the capsules three in number, and the latter of an obcordate shape. There are two species, scandent plants of the West Indies.

HIPPOCREPIS, *common horse-shoe-vetch*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The legumen is compressed and crooked, with many incisions on the interior suture. There are five species, two natives of the warm parts of Europe, and one of Britain. They are all low herbaceous trailing plants, with yellow flowers. They are propagated by seeds; but having no great beauty are seldom kept in gardens.

HIPPOMANE, the *manchineel-tree*, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. The male has an amentum and bifid perianthium, without any corolla; the female perianthium is trifid; there is no corolla; the stigma is tripartite; and the plum or capsule tricoccous. See Plate. The species are,

1. The mancinella, with oval sawed leaves, is a native of all the West Indie islands. It has a smooth brownish bark. The flowers come out in short spikes at the end of the branches, but make no great appearance, and are succeeded by fruit of the same shape and size with a golden pippin. The tree grows to the size of a large oak.

2. The biglandulosa, with oblong bay leaves, is a native of South America; and grows to as large a size as the first, from which it differs mostly in the shape of its leaves.

3. The spinosa, with holly leaves, is a native of Campeachy, and seldom rises above 20 feet high; the leaves greatly resemble those of the common holly, and

are set with sharp prickles at the end of each indenture. They are of a lucid green, and continue all the year.

These plants being natives of very warm climates cannot be preserved in this country without a stove; nor can they by any means be made to rise above five or six feet high even with that assistance. They are propagated by seeds; but must have very little moisture, or they will certainly be killed by it.

These trees have a very poisonous quality, abounding with an acrid milky juice of a highly caustic nature. Strangers are often tempted to eat the fruit of the first species; the consequences of which are, an inflammation of the mouth and throat, pains in the stomach, &c. which are very dangerous, unless remedies are speedly applied. The wood is much esteemed for making cabinets, book-cases, &c. being very durable, taking a fine polish, and not being liable to become worm-eaten: but as the trees abound with a milky caustic juice already mentioned, fires are made round their trunks to burn out this juice, otherwise those who fell these trees would be in danger of losing their sight by the juice flying in their eyes. This juice raises blisters on the skin wherever it fails, turns linen black, and makes it fall out in holes. It is also dangerous to work the wood after it is sawn out; for if any of the sawdust happens to get into the eyes of the workmen it causes inflammation; to prevent which they generally cover their faces with fine lawn during the time of working the wood. It is with the juice of this tree that the Indians used to poison their arrows.

HIPPOPHAE, *sea-buckthorn*, a genus of the tetrandria order, in the diœcia class of plants, and in the natural method ranking under the 16th order, calycifloræ. The male calyx is bipartite; there is no corolla; the female calyx is blind; there is no corolla; there is one style, and a monospermous berry. The species are,

1. The rhamnoides, with a shrubby stem. branching irregularly eight or ten feet high, having a dark-brown back.

2. The canadensis has a shrubby brown stem, branching eight or ten feet high, with oval leaves, and male and female flowers on different plants. Both these species are very hardy, and may be propagated in abundance by suckers from the roots, by layers, and by cuttings of their young shoots. They are retained in gardens on account of their two-coloured leaves in summer; and in winter on account of the appearance of the young shoots, which are covered with turgid, irregular, scaly-buds. Goats, sheep, and horses, eat the first species; cows refuse it.

HIPPOPOTAMUS, a genus of quadrupeds of the order of belluæ. The generic character is, the front teeth of the upper jaw are four, and placed in pairs; those of the lower jaw are prominent, and the intermediate ones are protruded forward; the canine teeth are single, and obliquely truncated; the teats are only two, and placed near the groin. It is a native of the warmer regions of the globe, and is chiefly found in the middle parts of Africa, inhabiting large rivers, and especially such as run through countries overshadowed by large forests; walking about at the bottom, and raising itself at intervals to the surface, for the purpose of respiration. By night it quits its watery residence, to graze in the neighbouring plains, devouring great quantities of herbage, and with its vast teeth destroying the more tender kinds of trees and other vegetables. It is sometimes seen even in the sea, at some distance from the mouths of rivers, but this is supposed to be merely for the purpose of exercise; for it will not even drink salt water, and does not prey on fish, or indeed live on any kind of animal food. The general size of the hippopotamus seems to be nearly equal to that of the rhinoceros, and it is sometimes even superior. Its form is highly uncouth; the body being extremely large, fat, and round; the legs very short and thick; the head very large; the mouth extremely wide, and the teeth of vast strength and size, more particularly the tusks or canine teeth of the lower jaw, which are of a curved form: they sometimes measure more than two feet in length, and weigh upwards of six pounds each. The whole animal is covered with short hair, which is much more thinly set on the under parts than on the upper. The hippopotamus when just emerged from the water appears of a palish-brown, or mouse colour, with a blueish or slate coloured cast, on the upper parts; and the belly is flesh coloured, the skin appearing through the hair. When perfectly dry the colour is an obscure brown, without any of the blueish cast. The skin is most excessively tough and strong, except on the belly, where it is considerably softer. Its voice is a peculiar kind of interrupted roar, between that of a bull and the braying of an elephant. When on land it moves in a somewhat slow and awkward manner; but if pursued, can run with considerable speed, and directly plunging into the water sinks to the bottom, and pursues its progress beneath. It is observed to be extremely cautious of making its appearance by day, especially in such places as are much frequented by mankind, scarcely lifting its nose above the surface while breathing; but it is fearless in rivers which run through unfrequented regions, where it is occasionally seen to rush out of the water with sudden impetuosity, trampling down every thing in its way; and at such time is, of course, highly dangerous. It is, however, naturally of a harmless disposition; not attacking other animals; but merely committing havoc in plantations of maize, rice, sugar-canes, &c. and destroying the roots of trees, by loosening them with its vast teeth. It is capable, notwithstanding its great bulk, of swimming very swiftly. Sometimes hippopotami are seen going in herds, or companies, to the distance of some miles from the bank of a river in quest of food. If wounded in the water they become furious, and are said to attack the boats or canoes whence the injury proceeded, and either overturn or sink them, by biting out large pieces from the bottom. The hippopotamus sleeps in the small reedy islets which are found here and there in the rivers it frequents. In such spots it also brings forth its young; having only one at a birth, which it nurses with great care for a considerable time. The young is capable of being tamed, and we are assured by Belon that he saw one so gentle as to show no inclination to escape, or to do any kind of mischief when let out of the stable in which it was kept.

These animals are said to be most successfully taken by preparing pitfals for them, of large size, near the rivers. They are also occasionally shot, or killed with harpoons. Their flesh is reckoned good by the Africans, and the fat is said to be a fine kind of lard. But it is

chiefly on account of the teeth, and more particularly of the tusks, that this animal is killed; their hardness being superior to that of ivory, at the same time that they are not so subject to become yellow, for which reason they are much used by the dentists. The skin, from its great thickness and strength, when dried, is used by the African nations for bucklers or shields, and is said to be proof against the stroke of a bullet; and indeed the living animal, if shot at any where but on the head or the belly, is scarcely vulnerable, the tough skin causing a bullet to glance from its surface.

The largest female hippopotamus killed by colonel Gordon was about 11 feet long, and the largest male, which always exceeds the female size, about 11 feet 8 inches. Mr. Bruce, however, speaks of hippopotami in the lake Tzana of more than twenty feet long.

The hippopotamus has only a single stomach, and does not ruminate: the stomach, however, has certain cells and divisions, analogous, in some degree, to those of the camel.

M. Sonnini thinks it not improbable that there may in reality exist two species of hippopotamus; one of which confines itself entirely to rivers and fresh waters, and the other to the sea. See Plate LXVII. Nat. Hist. fig. 226.

HIPPURIS, *mare's tail*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the 15th order, inundatæ. There is no calyx, nor any petals; the stigma is simple; and there is one seed. There are three species, one a native of Britain, and which grows in ditches and stagnant waters. The flower of this plant is found at the base of each leaf, and is as simple as can be conceived; there being neither empalement nor blossom; and only one chive, one pointal, and one seed. It is a very weak astringent. Goats eat it; cows, sheep, horses, and swine, refuse it.

HIRÆA, a genus of the trigynia order, in the decandria class of plants. The calyx is pentaphyllous; the petals roundish and ungniculated; there are three bilabiated seeds. There is one species, a tree of New Spain.

HIRCUS, a goat, in astronomy, a star of the first magnitude, the same with capella. See CAPELLA and ASTRONOMY.

HIRTELLA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. There are five petals; the filaments are very long, persisting, and spiral; the berry is monospermous; the style lateral. There are three species, trees of the West Indies.

HIRUDO, the *leech*, a genus of insects belonging to the order of vermes intestina. The body moves either forward or backward. There are 17 species, principally distinguished by their colour. The most remarkable are the following:

1. The medicinalis, or medicinal leech, the form of which is well known, grows to the length of two or three inches. The body is of a blackish-brown colour, marked on the back with six yellow spots, and edged with a yellow line on each side; but both the spots and the lines grow faint, and almost disappear, at some seasons. The head is smaller than the tail, which fixes itself very firmly to any thing the creature pleases. It is viviparous, and produces but one young at a time, which is in the month of July. It is an inhabitant of clear running waters, and is well known for its use in bleeding.

2. The sanguisuga, or horse-leech, is larger than the former. Its skin is smooth and glossy; the body is depressed, the back is dusky; and the belly is of a yellowish-green, having a yellow lateral margin. It inhabits stagnant waters.

3. The geometra, or geometrical leech, grows to an inch and a half in length; and has a smooth and glossy skin of a dusky-brown colour, but in some seasons greenish spotted with white. When in motion its back is elevated into a kind of ridge; and it then appears as if measuring the space it passed over, like a compass, whence its name. Its tail is remarkably broad; and it holds as firmly by it as by the head. It is common on stones in shallow running waters; and is often found on trout and other fish after the spawning season.

4. The muricata, or muricated leech, has a taper body, rounded at the greater extremity, and furnished with two small tentacula, or horns, strongly annulated and rugged upon the rings, the tail dilated. It inhabits the Atlantic ocean, and is by the fishermen called the sea-leech. It adheres to fish, and generally leaves a black mark on the spot.

The mouth of the leech is armed with a sharp instrument that makes three wounds at once, and may be compared to the body of the pump, and the tongue or fleshy nipple to the sucker; by the working of this piece of mechanism the blood is made to rise up to the conduit which conveys it to the animal's stomach, which is a membranaceous skin divided into 24 cells. The blood which is sucked out is there preserved for several months, almost without coagulating, and proves a store of provision to the animal. The nutritious parts, pure and already digested by animals, have no call to be disengaged from the heterogeneous substances: nor indeed is there an anus discoverable in the leech: mere transpiration seems to be all that it performs, the matter fixing on the surface of its body, and afterwards coming off in small threads. Of this an experiment may be tried by putting a leech into oil, where it keeps alive for several days; upon being taken out and put into water, there appears to loosen from its body a kind of slough shaped like the creature's body. The organ of respiration, though unascertained, seems to be situated in the mouth; for if, like an insect, it drew its breath through vent-holes, it would not subsist in oil, as by it they would be stopped up.

It is only the first species that is used in medicine, being applied to the skin in order to draw off blood. With this view they are employed to phlebotomise young children. If the leech does not fasten, a drop of sugared milk is put on the spot it is wished to fix on, or a little blood is drawn by means of a slight puncture, after which it immediately settles. The leech when fixed should be watched, lest it should find its way into the anus when used for the hemorrhoids, or penetrate into the œsophagus if employed to draw the gums, as it would make great havoc in the stomach or intestines. In such a case, the best and quickest remedy is to swallow some salt; which is the method practised to make it loose its hold when it sucks longer than was intended. Salt of tartar, volatile alkali, pepper, and acids, make it also leave the

part on which it was applied. Cows and horses have been known to receive them, in drinking, into the throat. The usual remedy is to force down some salt, which makes them fall off. The discharge occasioned by the puncture of a leech is usually of more service than the process itself. When too abundant it is easily stopped with brandy, vinegar, or other styptics, or with a compress of dry linen rag bound strongly on the bleeding orifice.

At Ceylon, travellers who walk bare-legged are molested by the great numbers of leeches concealed under the grass. All leeches vary in their colours at some seasons, but they are generally of a dusky greenish-brown or yellow, and often variegated. They are said to be very restless before a change of weather, if confined in glasses.

HIRUNDO, in ornithology, a genus of birds of the order of passeres. There are 37 species, chiefly distinguished by their colour. The most remarkable are,

1. The rustica, common or chimney-swallow, is distinguished from all the other species by the superior forkiness of its tail, and by the red spot on the forehead and under the chin. The crown of the head, the whole upper part of the body, and the coverts of the wings, are black, glossed with a rich purplish blue, most resplendent in the male: the breast and belly white, and in the male tinged with red. The food of this swallow is the same with the others of its kind, viz. insects. For the taking of these, in their swiftest flight, nature has admirably contrived their several parts: their mouths are very wide to take in flies, &c. in their quickest motions; their wings are long, and adapted for distant and continued flight; and their tails are forked, to enable them to turn the readier in pursuit of their prey. This species is the first comer of all the British hirundines; and appears in general on or about the 13th of April, though now and then a straggler is seen much earlier. This hirundo, though called the chimney-swallow, by no means builds altogether in chimneys, but often within barns and out-houses against the rafters; and so she did in Virgil's time. In Sweden she builds in barns, and is called *ladu swala*, the barn-swallow. Besides, in the warmer parts of Europe there are no chimneys to houses except they are English built: in these countries she constructs her nest in porches, and gateways, and galleries, and open halls. Here and there a bird may effect some odd and peculiar place; but in general with us this species breeds in chimneys, and loves to haunt those stacks where there is a constant fire, no doubt for the sake of warmth. Not that it can subsist in the immediate shaft where there is a fire, but prefers one adjoining to that of the kitchen, and disregards the perpetual smoke of that funnel. Her nest consists, like that of the house-martin, of a crust or shell composed of dirt or mud, mixed with short pieces of straw to render it tough and permanent; with this difference, the shell of the martin is nearly hemispheric, that of the swallow is open at the top, and like half a deep dish: this nest is lined with fine grasses, and feathers which are often collected as they float in the air.

The bird lays from four to six white eggs, dotted with red specks; and brings out her first brood about the last week in June, or the first week in July. The progressive method by which the young are introduced into life is very curious: first, they emerge from the shaft with difficulty enough, and often fall down into the rooms below; for a day or two they are fed on the chimney top, and then are conducted to the dead leafless bough of some tree, where, sitting in a row, they are attended with great assiduity, and may be then called perchers. In a day or two more they become flyers, but are still unable to take their own food; therefore they play about near the place where the dams are hawking for flies; and when a mouthful is collected, at a certain signal given, the dam and the nestling advance, rising towards each other, and meeting at an angle; the young one all the while uttering such a little quick note of gratitude and complacency, that a person must have paid very little regard to the wonders of natore that has not often remarked this feat. The dam betakes herself immediately to the business of a second brood as soon as she is disengaged from her first; which she at once associates with the first broods of house-martins, and with them congregates, clustering on sunny roofs, towers, and trees. This hirundo brings out her second brood towards the middle and end of August.

Each species of hirundo drinks as it flies along, sipping the surface of the water; but the swallow alone, in general, washes on the wing, by dropping into a pool for many times together: in very hot weather house-martins and bank-martins dip and wash a little. The swallow is a delicate songster, and in soft sunny weather sings both perching and flying; on trees in a kind of concert, and on chimney-tops. Horsemen on wide downs are often closely attended by a little party of swallows for miles together, which plays before and behind them, sweeping around, and collecting all the sculking insects that are roused by the trampling of the horses' feet: when the wind blows hard, without this expedient, they are forced to settle to pick up their lurking prey.

This species feeds much on little coleoptera, as well as on gnats and flies; and often settles on dug-ground, or pats, for gravel to grind and digest its food. Mr. White informs us, that before they depart, for some weeks, to a bird, they forsake houses and chimneys, and roost in trees; and usually withdraw about the beginning of October; though some few stragglers may be seen at times till the first week in November. Mr. Pennant says, that for a few days previous to their departure, they assemble in vast flocks on house-tops, churches, and trees, whence they take their flight. They are supposed to take up their winter-quarters in Senegal and parts adjacent, and seem to possess in turn the whole of the old continent, being known from Norway to the Cape of Good Hope on the one hand, and from Kamtschatka to India and Japan on the other. They are also found in all parts of North America, migrating north and south.

2. The esculenta, or edible swallow, according to Buffon, is less than the wren, and only two inches and a quarter in length. The bill is black; the upper parts of the body are brown, the under whitish; the tail is forked, and each feather of it is tipped with white; the legs are brown. See Plate LXXIV. Nat. Hist. fig. 228.

The most curious part of the natural history of this bird consists in the nest, which is composed of such materials as render it not only edible, but one of the greatest dainties of the Asiatic epicures.

These nests are found in vast numbers in certain ca-

verns. in various isles in Soolo Archipelago, situated between longitude 117 and 120, latitude 5 and 7; particularly in three small isles, or rather rocks; in the caverns of which the nests are found fixed to the sides in astonishing numbers. Of these nests, it is said the Dutch alone export from Batavia 1000 pickles, upwards of 1300lb. English weight, every year, which are brought from the isles of Cochin China, and those lying to the east of them.

3. The urbica, or martin, is inferior in size to the chimney swallow, and its tail much less forked. The head and upper part of the body, except the rump, are black, glossed with blue; the breast, belly, and rump, are white; the feet are covered with a short white down. This is the second of the swallow kind that appears in Britain. They begin to appear about the 16th of April. About the middle of May, if the weather is fine, the martin begins to think in earnest of providing a mansion for its family. As this bird often builds against a perpendicular wall without any projecting ledge under, it requires its utmost efforts to get the first foundation firmly fixed, so that it may safely carry the superstructure. That this work may not, while it is soft and green, pull itself down by its own weight, the provident architect has prudence and forbearance enough not to advance her work too fast; but by building only in the morning, and by dedicating the rest of the day to food and amusement, gives it sufficient time to dry and harden. By this method in about 10 or 12 days is formed an hemispheric nest, with a small aperture towards the top, strong, compact, and warm, and perfectly fitted for all the purposes for which it was intended. But then nothing is more common than for the house-sparrow, as soon as the shell is finished, to seize on it as its own, to eject the owner, and to line it after its own manner. At first, when the young are hatched, and are in a naked and helpless condition, the parent birds, with tender assiduity, carry out what comes away from their young. Was it not for this affectionate cleanliness the nestlings would soon be burnt up and destroyed in so deep and hollow a nest by their own caustic excrement. As soon as the young are able to shift for themselves, the dams immediately turn their thoughts to the business of a second brood: while the first flight, shaken off and rejected by their nurses, congregate in great flocks, and are the birds that are seen clustering and hovering on sunny mornings and evenings on round towers and steeples, and on the roofs of churches and houses. As the summer declines the congregating flocks increase in numbers daily, by the constant accession of the second broods, till at last they swarm in myriads round the villages on the Thames, darkening the face of the sky as they frequent the aits of that river, where they roost. They retire in vast flocks together about the beginning of October. Unless these birds are very short-lived indeed, or unless they do not return to the district where they are bred, they must undergo vast devastations somehow, and somewhere; for the birds that return yearly bear no manner of proportion to the birds that retire.

4. The riparia, sand-martin, or shore-bird, is $4\frac{3}{4}$ inches in length, with the whole upper parts of the body of a mouse colour, the throat and under parts white, the bill and legs blackish. It is common about the banks of rivers and sand-pits, where it terebrates a round and regular hole in the sand or earth, which is serpentine, horizontal, and about two feet deep. At the inner end of this burrow the bird deposits her rude nest, consisting of fine grasses and feathers, usually goose-feathers, very inartificially laid together.

5. The apus, or swift, is a large species, being near eight inches long, with an extent of wing near 18 inches, though the weight of the bird is only one ounce. Their feet are so small, that the action of walking and rising from the ground is extremely difficult; but nature has made it full amends, by furnishing it with ample means for an easy and continual flight. It is more on the wing than any other swallow; its flight is more rapid, and that attended with a shrill scream. It rests by clinging against some wall, or other apt body; whence Klein styles this species hirundo muraria. It breeds under the eaves of houses, in steeples, and other lofty buildings; and makes its nest of grasses and feathers. The feet of this species are of a particular structure, all the toes standing forward: the least consists of only one bone; the others of an equal number, viz. two each, in which they differ from those of all other birds: a construction, however, nicely adapted to the purposes in which their feet are employed. See Plate LXXIV. Nat. Hist. fig. 227.

The swift is a summer inhabitant of Great Britain. It comes the latest, and departs the soonest, of any of the tribe; not always staying to the middle of August, and often not arriving before the beginning of May.

6. The melba, or white bellied swift, is in length eight inches and a half, and weighs two ounces five drams.

7. The cayennensis, or white coloured swallow, is about the size of the martin: the head and bill are black; the chin and throat white, passing from the last in a narrow collar round the neck: between the bill and eye is a streak of white, which forks off into two, one passing a little above, and the other a little way beneath the eye: the rest of the plumage is black, with a gloss of violet; but the greater coverts, nearest the body, are brown edged with white. This bird makes its nest in the houses of Cayenne. It is of a large size, in shape of a truncated cone; five inches one way by three the other, and nine inches in length. It is composed of the down of dog's-bane, well woven together; the cavity divided obliquely about the middle, lengthways, by a partition, which spreads itself over that part of the nest where the eggs lie, which is pretty near the base: a small parcel of the same soft down, forming a kind of plug, is placed over the top, serving to keep the young brood from the impression of the air, from which we may suppose them to be very tender.

By the myraids of insects which every single brood of swallows destroys in the course of a summer, they defend us in a great measure from the personal and domestic annoyance of flies and gnats; and, what is of infinitely more consequence, they keep down the numbers of our minute enemies, who, either in the grub or winged state, would otherwise render the labours of the husbandman fruitless. Since then swallows are guardians of our corn, they should every where be protected by the same popular veneration which in Egypt defends the ibis, and the stork in Holland. We more frequently hear of unproductive harvests on the Continent and it is well known

that swallows are caught and sold as food in the markets of Spain, France, and Italy. In England they are not driven to such resources to furnish their tables. But what apology can be made for those, and many there are, whose education and rank should have taught them more innocent amusements, who wantonly murder swallows, under the idle pretence of improving their skill in shooting game? Setting aside the cruelty of starving whole nests of young by killing the dam; those who follow this barbarous diversion would do well to reflect, that by every swallow they kill, they assist blasts, mildews, and vermin, in causing a scarcity of bread. Every lord of a manor should restrain his gamekeeper from this execrable practice; nor should he permit any person to sport on his lands who does not refrain from it.

HISPA, in zoology, a genus of insects belonging to the coleoptera order, the characters of which are these: the antennæ are fusiform, growing gradually larger from each extremity towards the middle, and are situated between the eyes; the thorax and elytra are covered with protuberances or spines. The larva of this insect seems to be yet wholly unknown. There are but two species of the perfect animal met with in Europe; one of which, the atra, is found in Britain, and is all over of a deep unpolished black, and has the upper part of its body entirely covered with long and strong spines, which render it bristly like the shell of a chesnut. There is even a spine at the case of the antennæ; the thorax has a row set transversely, which are forked; and the elytra are furnished with a very great number that are single. Its being thus covered with spines makes it resemble a hedge-hog in miniature. It is rather hard to catch, letting itself fall down to the ground as soon as approached. It bears its antennæ upright before it. See Plate LXXIV. Nat. Hist. fig. 229.

HISTER, a genus of insects of the coleoptera order. The generic character is, antennæ headed by a somewhat solid tip, lowest joint compressed and decurved; head retractile; mouth forcipated; wing-sheaths shorter than the body; fore-legs toothed.

The most common European species of this genus is the hister unicolor of Linnæus. It is entirely of a glossy coal-black colour, and of a slightly flattened shape, varying considerably in size, but usually measuring about the third of an inch in length, and is often seen in gardens, sandy fields, &c. Its larva seems to be unknown.

Hister quadrimaculatus, has much the appearance of a small beetle; its shape is strongly convex, and its colour black, with two dull-red bars on each wing-shell, viz. one at the base, and the other, smaller, at the tip. It is found about dunghills, &c.

HISTORY, *civil.* History, in its simplest definition, implies the mere narration of events and facts; but when placed in its true dignity, it is something more than this, it is philosophy "teaching by examples." The study of it is more or less the employment of all persons of reading and education; and the composition of it was the earliest use that was made of letters, since the first poems were historical: it is calculated for the use of all ranks and all professions in life, and places the reader of its events as a spectator out of all hazards, who may reap wisdom from the danger of others, and foretel, to a certain extent, the future by the past.

The general uses of history are exhibited by Dr. Priestley under three heads: 1. He says, history serves to amuse the imagination, and interest the passions in general. 2. It improves the understanding: and, 3. It tends to strengthen the sentiments of virtue. In the first of these views we find history has a great advantage over every work of fiction: for we consider it as the voice of truth. The second has been aptly illustrated by Bolingbroke, who observes that "He who studies history as he would philosophy, will distinguish and collect certain general principles and rules of life and conduct, which always must be true, because they are conformable to the invariable nature of things; and by doing so he will soon form to himself a general system of ethics and politics on the surest foundations, on the trial of these principles and rules in all ages, and on the confirmation of them by universal experience." And the third is still more evident, from the very light in which characters and events are seen in it. Fame is found just to the dead, however partial to the living.

The sources of history form another topic of inquiry. The earliest of these was undoubtedly tradition; the next, perhaps, poetical narrations; which, though often mixed with the absurdities of fable, contain facts and characters of ancient life that illustrate the manners of the early ages. Coins, medals, and inscriptions, the works of artists of all kinds, and sometimes even rude heaps, are other monuments, whose collateral aids are equally necessary with the astronomical mediums employed by Newton, in the correction of chronology. I later times, as political society increased, the archives and laws of states perpetuated information in a more certain and extended form. The correct knowledge of events was easily obtained. Private experience could be joined to the information contained in public annals; and fair topics were presented to the pen of every man who proposed to himself the task of an historian.

In regard to what is necessary or useful to be known previous to the study of history, it is proper to observe that it must be taken in very different degrees of extent, according to the views with which history is read; and these depend very much upon the age and situation of the person who applies to it. But whoever proposes to study history scientifically, must come to the reading of it furnished with the first principles of certain sciences. If not the knowledge, at least a general idea of the principles of human nature, will be an excellent guide to us in judging of the consistency of human characters, and of what is within and what is without the reach of human powers. Philosophical knowledge, in general, will be found of the most extensive use to all persons who would examine with accuracy the achievements of ancient nations in peace or war, or who would thoroughly weigh the accounts of any thing in which the powers of nature are employed. But those sciences which are of the most constant and general use are geography and chronology. A knowledge of the situation and relative magnitude of the several countries of the earth, assists and affords clear and distinct ideas of events; and a general comprehenion of the current of time enables us distinctly to trace their dependence on each other.

Beside these, however, there are other helps. Obvious advantages will attend the use of a good compendium of general history, previous to the study of any particular portion. The earliest epitome was the Chronicon Carionis, printed at Wittenberg, 1532; but the most celebrated are, Turseline's, Bossuet's, and Baron Holberg's; the last of these was translated into English by Mr. Gregory Sharpe. Of chronological tables the best and most completely useful are Blair's: and of the charts of history, Dr. Priestly's These show at once the reference which the history of one country bears to that of another.

The misapplication to which history is liable, evinces the necessity of prosecuting the study of it according to a regular plan. To those who can reach its sources these directions may be serviceable: principally obtained from Dr. Priestley.

The sacred history may properly be said to stand alone: it is not only the most certain, but exhibits the continuation of the true religion uninterrupted from the creation of the world, and therefore ought to form the ground-work of our study.

The oldest history extant, next to the historical books of the Old Testament, is that of Herodotus, who flourished about four hundred and fifty years before the christian era, a little after the invasion of Greece by Xerxes. His history comprises probably every thing he had an opportunity of learning concerning the history of the Lydians, Ionians, Lycians, Egyptians, Persians, Greeks, and Macedonians: computing from the earliest of his accounts to the latest, his history may be reckoned to commence about seven hundred and thirteen years before Christ, and to reach to about four hundred and seventy-nine before Christ; a period of about two hundred and thirty-four years.

Next to Herodotus, Thucydides is to be read, whose history reaches to the 21st year of the Peloponnesian war, the history of which is completed in the first and second books of Xenophon's History of Greece. After this, the student may proceed to the expedition of Cyrus, and the return of the Greeks: and then go back to the remaining-books of Xenophon's history. The fifteenth and sixteenth books of Diodorus Siculus contain the histories of Greece and Persia from the battle of Mantinæa to the beginning of the reign of Alexander the Great, in the year 336 before Christ. For the history of Alexander, Arrian, Quintus Curtius, and the tenth and eleventh books of Justin must be referred to. The eighteenth, nineteenth, and twentieth books of Diodorus Siculus contain the history of Greece from the year 323 before Christ, to the year 301: the thirteenth, fourteenth, and fifteenth books of Justin will complete the period; and those which follow to the twenty-ninth inclusive, carry on the history to about the year 195 A. C. Lastly, in the regular order of history read the thirteenth book of Justin, and all that follow to the two last, which completes the History of Greece till it mixes with that of the Romans.

The lives of illustrious men by Plutarch and Cornelius Nepos, form an excellent supplement to the regular historians.

Of the above works, which contain not only the History of Greece, but that of all the nations of the world known to the historians, Justin, Quintus Curtius, and Cornelius Nepos, only, are in Latin; the rest are in Greek.

The following course of Roman History comprehends all that is to be learnt now of the subsequent Ancient History of all other nations. The writer who treats of the early part of the Roman history, in the fullest and most satisfactory manner is Dionysius of Halicarnassus, a rhetorician as well as an historian: the remains of his work which originally brought the History of Rome to the beginning of the first Punic war, end at this time with the year 341 before Christ, the time when the consuls resumed the chief authority in the republic after the dissolution of the decemvirate: so that to complete the period we must go to the three first books of Livy, whose history to the tenth book inclusive, brings that of Rome to the year 451, of the building of the city or 292 before Christ. To supply the chasm between the tenth and twentieth books of Livy, read Polybius, the seventeenth, eighteenth, twenty-second, and twenty-third books of Justin, and Appian's Punic and Illyrian wars, and afterwards the remainder of Livy from the twenty-first book to the end, which brings the history to 166 years before Christ. Sallust's History of the war of Jugurtha and the Catalinarim conspiracy, are the next books to be proceeded to: they are all which remains to us of his works. The commentaries of Cæsar, and Cicero's Epistles to Atticus, are the next works to be consulted, followed by the remains of Dio Cassius, and the Compendium of Vellerius Paterculus. Suetonius's Lives of the Cæsars, and the works of Tacitus, close the list of Roman historians of the greatest eminence. Those who are called the writers of the brazen or iron age deserve a slighter mention. The principal of these are, Xiphilin, Herodian, The Historiæ Augustæ Scriptores, Zozimus, Ammianus Marcellinus, Paulus, Deaconus, and Procopius; the last four, however, may be omitted; and Nicetas Acominatus and Nicephorus Gregoras, followed by Joannes Cantacuzenus, substituted in their room. Laonicus Chalcondiles brings up the conclusion of the Eastern Empire, in the year 1453, when Constantinople was taken by Mahomet II.

To enumerate all the modern compilations of ancient history which may be serviceable to those who cannot make their searches in the original authors would be endless. That of Rollin must not be passed over. The most complete body of history, however, ancient and modern, is the Universal: which has references to the original writers for almost every paragraph of information. Gillies and Mitford have written Histories of Greece, and Hooke is by far the most preferable among the compilers of the Roman history.

Having been thus particular on the subject of ancient history, we shall go on to the enumeration of those sources from which the last materials are derived for English history; and then proceeding to the other countries of modern Europe, make a slight mention of the best historians of each.

The earliest accounts of Britain are to be found among the Romans; and principally in the works of Julius Cæsar, Dio Cassius, and Tacitus. Livy and Fabias Rusticus were others who wrote expressly on its history; but their works have perished in the general wreck of ancient literature.

The most ancient of our native historians, now extant, says bishop Nicholson, is Gildas, a monk of Bangor, who lived about the middle of the sixth century; a sorrowful spectator of the miseries and almost utter ruin of his countrymen, by a people under whose banners they hoped for peace. The title of his work was, "De Excidis Britanniæ." The next historian of note was Nennius, who is often confounded with Gildas: his work, which has gone by different names, was printed by Gale under that of "Historia Britonum." If we except a supplement to these writers, in the laws of Hoel Dha, we have nothing more of early British history. Geoffrey of Monmouth's work, which was written at a subsequent period, is nothing more than a romance.

For the history of the Saxon times we have better materials, the oldest of which, perhaps, that are now preserved, are in the Saxon Chronicle, printed from several manuscripts by bishop Gibson. Next to this Bede's Ecclesiastical History may be placed, and the Life of Alfred by Aser of St. David's.

Only two Danish historians, says bishop Nicholson, are necessary to the English antiquary's library; Saxo Grammaticus and Sweno Agonis.

The first English historian after the Norman Conquest, was Ingulph, abbot of Crozland, whose history extends from the year 626 to 1089. That portion of Marianus Scotus's history which relates to Britain never has been printed. Florence of Worcester's, who died 1119, is more full.

Eadmer's work, published by Mr. Selden, contains the history of the two Williams and Henry the First, from 1066 to 1122, and is a work of very good authority.

William of Malmsbury was the next historian, whose book "De Gestis Rebus Anglorum," is one of the most faithful of our numerous annals: it begins with the first arrival of the Saxons, and is continued to the death of Stephen. The other historians of the twelfth century were, Simeon Dunelmensis, Henry of Huntingdon, and William of Neuburg.

Gervase of Canterbury's history, of which a fragment only is left, is the earliest of the thirteenth century: his chief contemporary was Hoveden, who seems to have been chaplain to king Henry the Second. Ralph de Diceto, Walter of Coventry, and Matthew Paris, were others. There were likewise a few meaner historians, whose names it is not necessary to repeat.

The principal writers of the fourteenth century were, Wikes, Trivet, John Brompton, Higden, John of Tinmouth, Matthew of Westminster, and Knighton: the last but one of whom is often called Florilegus.

The first and principal writer of the fifteenth century was Froissart, whose work has been so carefully translated by Mr. Johnes. It affords the best history of the English Nation during the reigns of Edward the Third and Richard the Second. Thomas de Walsingham is the next writer of credit, succeeded by John Harding, Caxton, and Rouse.

Fabian's Chronicle is the first work of consequence in the sixteenth century, and is said to have given great offence to Wolsey. Polydore Virgil's history is not believed to have been so faithful; though greater merit is attributed to the works of Hall and Hollinshead.

The industrious Stowe was the first writer among the historians of the seventeenth century: the next of eminence was Daniel Speed, sir Richard Baker, Sandford, Brady, Echard and Tyrrel, are others, whose names only it is quite sufficient to enumerate.

In the last century, bishop Burnet, Carte, Kennet, Tindal, Hume, Smollet, Macaulay, and Henry, are historians too well known to need either comment or commendation here.

In regard to the writers of particular histories of the kings with whom they were cotemporary, it may be sufficient to enumerate the following: William the Conqueror's life was written by William of Poictiers; king Stephen's memoirs, by Richard Prior of Hexham, printed among the decem-scriptores; Richard the First's Expedition into the Holy Land, was celebrated by Joseph of Exeter, or Iscanus; the Life of Edward the Second by sir Thomas de la More: Henry the Fifth's by some one under the name of Titus Livius: and that of Edward the Fifth, with a part of the History of Richard the Third, by sir Thomas More; Henry the Eighth's Reign, by lord Herbert of Cherbury; and Elizabeth's by Camden. Those of a later period, perhaps, are hardly entitled to so much credit for impartiality.

The historians of other particular countries may be mentioned in a briefer manner; enumerating such only as a reader may refer to when inquiring into facts. In regard to France, after mentioning the Chroniques de St. Denis, the Annales Francorum, with the works of Monstrelet, Mezeray, Daniel and Garnier, and Henault's Abridgement, we need only mention two of the most comprehensive bodies of French history, "Duchesne's Historiæ Francorum Scriptores;" and "Bouquet's Recueil des Historiens des Gaules et de la France," in thirteen volumes folio. For the general history of Italy, Guicciardini's work is undoubtedly the best, not only for its accuracy but its style; though Brusoni's and Capriata's works are much esteemed for their veracity. To those who make a deep search, the "Rerum Italiarum Scriptores," by Muratori, will be useful.

For the separate states of Italy Giannoni's History of Naples, Machiavel's Historia Florentina, and the "Historia Veneziani." For Switzerland, the "Helvetic Confederacy" by Mr. Planta, may be referred to: for Holland, Le Clerc's "Provinces Unies," 1728. Among the writers of German history, the "Germani Scriptores" of Pistorius, Urstilius, Freher, and Reuber, may be mentioned; the writers on ancient Germany by Sicard; the Scriptores Rerum Bronsvicensium; and Mascou's history of the Germans.

The most valuable history of Spain is Mariana's, first published in 1592; the best edition of which, continued to a late period, was published at Valencia 1783. Besides this, Carita's "Annales de Arragon" may be consulted with the "Annales de Cattaluna." The earliest materials for Portuguese history are to be found among the Scriptores Rerum Hispaniarum. The first historian whom Meusel mentions is Laimund de Ortega: but one of the most valuable and industrious was Bernard de Brito, who published the two first parts of the "Monarchia Lusitana," in 1597 and 1609; which was continued as far as an eigth part, in 1729. Others are, Meneze's Historia de Portugal, printed at Lisbon

in two volumes, folio, 1679 and 1698; La Clede's Histoire de Portugal, Par. 1737; and the elaborate history of Gebauer, in German, Leipsig, 1759. On Sweden, Crusius's "Annales Suevicæ," 1596, and Puffendorf "de Rebus Suevicis," 1686, will be found works of considerable consequence. On Norway, Forfæus's "Historia Rerum Norvegicarum." On Denmark, Cragius's "Annales Danicæ;" Mallet's "Histoire de Dannemarc," and Langebek's "Scriptores Rerum Danicarum:" and on Russia, "Rerum Muscovitarum Scriptores," 1600, folio, and Levesque's "Histoire de Russie," 1800. Those who would gain a more particular knowledge of the characters which the principal of these historians bear, may consult the works of Wheare and Rawlinson on History.

There are, however, some particular histories, which are so excellently written, that no person of a liberal education should neglect becoming acquainted with them. Under this character we may comprehend all the works of Tacitus, which now remain to us: in his writings every phrase is a maxim; the narrative goes on with rapidity; while all his characters are drawn with a more profound knowledge of human nature than those of any historian who went before him; his very brevity is pregnant. Thuanus's history of his own times is a work almost equal to any production of the classic ages. Guicciardini's History of Italy: Davila's of the Civil Wars of France; Bentivoglio's of those of the Netherlands; and Giannoni's History of Naples, deserve a similar character, as well as the elegant history of England by Hume. No writer whatever, says Dr. Priestley, can excel Vertot in the happy art of making history entertaining.

There are also periods of history more particularly deserving of a close attention. Among these the connection of sacred and profane history in the succession of the four great monarchies, stands foremost. Another period is that which comprises the history of the Grecian commonwealths, in which the peculiar evils and advantages of a popular government are exhibited with clearness. The rise and declension of the Roman empire is another object for extensive contemplation, as well as the foundation of the present European governments, and the restoration of learning.

We have now only to add a few words on the particular duty of the historian; the model for whom is preserved among the works of Cicero. It is the first law of history, he says, that the writer should neither dare to advance what is false, nor to suppress what is true; that he should relate the facts with strict impartiality, free from ill-will or favour; that his narrative should distinguish the order of time, and when necessary, give the description of places; that he should unfold the statesman's motives, and in his account of the transactions and the events, interpose his own judgment; and should not only relate what was done, but how it was done; and what share, chance, or rashness, or prudence, had in the issue; that he should give the characters of the leading men their weight and influence, their passions, their principles, and their conduct through life. In addition to these, Tacitus gives another rule: "Præcipuum munus annalium reor, ne virtutes sileantur, utque pravis dictis factisque ex posteritate et infamia metus sit:" that it is incumbent on the writer to rejudge the actions of men, to the end that the good and worthy may meet with the reward due to eminent virtue, and that pernicious citizens may be deterred by the condemnation that waits on evil deeds at the tribunal of posterity. In this consists the chief part of the historian's duty.

Let it be remembered that in this country, it is an indispensable duty of every man of liberal birth, to be acquainted in a certain degree with the science of politics. History is the school of politics: it unfolds to us the springs of human affairs; the causes of the rise, grandeur, revolutions, and fall of empires. It points out the reciprocal influence of government and of national manners: it dissipates prejudices, nourishes the love of our country, and directs to the best means of improvement. It illustrates equally the blessings of political union and the miseries of faction.

As to the events that stand recorded in history, says lord Bolingbroke, we see them all, we see them as they followed one another, or as they produced one another, causes or effects, immediate or remote. We are cast back, as it were, into former ages; we live with the men who lived before us, and we inhabit countries that we never saw. Place is enlarged, and time prolonged in this manner; so that the man who applies himself early to the study of history may acquire in a few years, and before he sets his foot abroad in the world, not only a more extended knowledge of mankind, but the experience of more centuries than any of the patriarchs saw. The events we are witnesses of in the course of the longest life, appear to us very often original, unprepared, simple, and unrelative; they appear such very often, are called accidents, and looked upon as the effects of chance: experience can carry us no farther, for experience can go a very little way back in discovering causes; and effects are not the objects of experience till they happen. Hence many errors in judgment, and by consequence in conduct, necessarily arise; and here too lies the difference we are speaking of between history and experience: the advantage on the side of the former is double. In ancient history the examples are complete, which are incomplete in the course of experience; experience is doubly defective; we are born too late to see the beginning, and we die too early to see the end of many things. History supplies both these defects. Modern history shows the causes when experience presents the effects alone; and ancient history enables us to guess at the effects when experience presents the causes alone.

HITCH, in the sea language, is to catch hold of any thing with a hook or rope, and by this means to hold it fast: thus when a boat is to be hoisted in, the sailors say, hitch the tackles into the ring-bolts of the boat; and when they are about to weigh anchor, hitch the fish-hook to the fluke of the anchor.

HIVE, in country affairs, a convenient receptacle for bees. See Apis.

HOARSENESS. See Medicine.

HODMAN, an appellation given to a young student admitted into Christ's College, Oxford, from Westminster-school.

HOE, a husbandman's tool somewhat like a cooper's adze, to cut up weeds in gardens, fields, &c. This instrument is of great use, and ought to be much more employed than it is in hacking and clearing the several cor-

ners and patches of land in spare times of the year, which would be no small advantage to it.

HOEING, in the new husbandry, is the breaking or dividing the soil by tillage while the corn or other plants are growing thereon. It differs from common tillage (which is always performed before the corn or plants are sown or planted) in the time of performing it; and it is much more beneficial to the crops than any other tillage. This sort of tillage is performed various ways, and by means of different instruments.

HOG. See SUS.

HOG, on board of a ship, is a sort of flat scrubbing broom, formed by inclosing a number of short twiggs of birch or such wood between two pieces of plank fastened together, and cutting off the ends of the twigs. It is used to scrape the filth from a ship's bottom under water, particularly in the act of boot-topping. For this purpose they fit to this broom a long staff with two ropes; one of which is used to thrust the hog under the ship's bottom, and the other to guide and pull it up again close to the planks.

HOGSHEAD, in commerce, a measure of capacity, containing sixty-three gallons.

HOLCUS, Indian millet or corn; a genus of the monœcia order, in the polygamia class of plants; and in the natural method ranking under the 4th order, gramina. The calyx of the hermaphrodite is an unifloroas or biflorous glume; the corolla is a glume with an awn; there are three stamina, two styles, and one seed. The male calyx is a bivalved glume; there is no corolla, but three stamina.

Of this genus there are fifteen species, two of which are natives of Britain. The most remarkable of these is the lanatus, or creeping soft-grass of Hudson. The most remarkable of the foreign species is the sorghum, or Guinea-corn. The stalks are large, compact, and full eight feet high. In Senegal the fields are entirely covered with it. The negroes, who call it guiarnot, cover the ears when ripe with its own leaves to shelter it from the sparrows, which are very mischievous in that country. The grain made into bread, or otherwise used, is esteemed very wholesome. With this the slaves in the West Indies are generally fed, each being allowed from a pint to a quart every day. The juice of the stalks is so agreeably luscious, that, if prepared as the sugarcanes, they would afford an excellent sugar.

HOLOCENTRUS. Holocentrus, a genus of the order thoracici; the generic character is, habit of the genus perca; gill-covers scaly, serrated, and aculeated; scales in most species, hard and rough. There are 35 species, the principal of which are:

1. Holocentrus sogo, a highly beautiful species: general length about a foot; habit somewhat resembling that of a carp, but of a squarer form, growing suddenly slender near the tail; eyes very large and gold-coloured; tail very much forked. Native of the Mediterranean, Indian, and American seas, and considered as an excellent fish for the table.

2. Holocentrus schraetzer: length about ten inches; shape somewhat lengthened; head destitute of scales, for which reason this species is by Dr. Bloch arranged under a distinct genus by the name of gymnocephalus: scales rather small than large; tail slightly divided; lowest of the longitudinal lines composed of a row of spots; dorsal fin spotted with black; native of the Danube and its tributary streams; in considerable esteem as an article of food.

3. Holocentrus decussatus, decussated holocentrus: length about twelve inches; back dusky brown; sides marked by two longitudinal brown stripes from the gills to the tail, and by seven transverse ones, each continued to some little distance into the dorsal fin, which is white or pale; scales middle-sized; eyes blue; tail brown, and slightly lunated.

4. Holocentrus calcarifer, spur-gilled holocentrus; length about a foot; habit that of a carp, but rather more lengthened in proportion; body marked by dusky lines along each row of scales; anterior gill-covers furnished with four strong sharp spines, so placed as to bear some resemblance to the rowel of a spur; posterior gill-covers armed with a single spine: fins and tail marked across the rays by brown spotted streaks; native of Japan.

5. Holocentrus surinamensis, Surinam holocentrus: length twelve inches; habit of a carp; general colour brown, with several large, roundish, obscurely-yellow patches on each side; head and gill-covers red; mouth small; dorsal fin scaly at the base of the back-part; tail crossed near the base by a brown bar: native of Surinam, where it is highly esteemed for the table, being considered as one of the best fishes which the country produces.

6. Holocentrus afer, African holocentrus; length twelve inches; outline of the body, exclusive of the fins, somewhat resembling that of a sole; thickness considerable; scales very small, but those on the posterior gill-covers considerably larger than the rest; dorsal fin covered with small scales, and furnished on the fore-part with extremely thick or strong spines; back part and anal fin rounded, and reaching to within a little distance of the tail, which is remarkably small for the size of the fish, and of a round shape; pectoral fins, whitish; ventral, pale red; native of the coast of Guinea, feeding on marine insects, &c. and in considerable estimation as a food.

HOLLY. See ILEX.

HOLOSTEUM, a genus of the trigynia order, in the
HOLLAND, in commerce, a fine and close kind of linen, so called from its being first manufactured in Holland.
triandria class of plants, and in the natural method ranking under the 22d order, caryophyllei. The calyx is pentaphyllous; the petals five; the capsule, unilocular, and nearly cylindrical, opening at top. There are five species.

HOLOTHURIA, in zoology, a genus belonging to the order of vermes mollusca. The body, detached, naked, gibbous, terminated by the anus. Many tentacula at the other extremity surrounding the mouth. There are nine species, all inhabitants of the ocean. The following descriptions of three species are given by Mr. Barbut.

1. The tremula, or quivering holothuria, "commonly measures eight inches in length when dead; but alive it extends itself to more than a foot, or contracts its body into a ball. Its figure is cylindric, the diameter of which is every way equal to an inch and a few lines. The belly is of a pale brown, and set all over with cylindric tentacula, in such numbers that the head of a pin could scarcely find room between. By the help of these tentacula,

the holothuria fixes its body at the bottom of the sea, so as not to be easily forced away by tempests, which would otherwise happen the more frequently, as this zoophite dwells near the shores where the water scarcely rises to a fathom's height.

2. The physalis, or bladder-shaped holothuria. The body of this species is oval, approaching to triangular, of a glossy transparency; the back sharp-edged, of a dark green colour, whence run out a number of sinews; anteriorily the body is of a reddish hue. The trunk spiral, reddish towards the thicker end. Many tentacula of unequal length under that thicker end; the shorter ones are taper and thicker, the middle ones capillary, the point clay-colour, and in shape like a ball; the rest, which are longer, are filiform, of which the middlemost is thicker and twice as long. Brown, in his Jamaica, calls it a diaphanous bladder with numerous tentacula representing a man's belly; above it is furnished with a comb full of cells; under the other extremity hang a number of branchy tentacula. It inhabits the seas.

3. The pentactes, or five rowed holothuria, has the mouth encompassed with tentacula, the body bearing tentacula five different ways. The animal is of a red colour, nearly oval, or somewhat cylindrical, assuming various shapes. The mouth is set round with ten rays, bristly at the points; the body is longitudinally dotted with warts. It inhabits the sea of Norway.

HOLY-GHOST, *order of the*, the principal military order in the old government of France, instituted by Henry III. in 1569.

HOLLOW-SQUARE, in the military art, a body of foot drawn up, with an empty space in the middle for colours, drums, and baggage.

Hollow-tower, according to Harris, is a rounding made of the remainder of two brisures, to join the curtin to the orillon, where the small shot are played, that they may not be so much exposed to the view of the enemy.

HOMAGE. In the original grants of lands and tenements by way of fee, the lord did not only tie his tenants to certain services, but also took a submission, with promise and oath to be true and loyal to him as their lord and benefactor. This submission was and is called homage.

Homage Ancestrel, is where a man's ancestors, time out of mind, held their land of their lord and his ancestors, by homage; and if such lord has received homage, he is bound to acquit the tenant against all other lords above him of all service; and if the tenant has done homage to his lord, and is impleaded, and vouches the lord to warranty, the lord is bound to warrant him; and if the tenant loses, he shall recover in value against the lord so much of the lands as he had at the time of the voucher, or any time after.

Homage Jury, a jury in a court baron, consisting of tenants that do homage to the lord of the fee, and there by the feudists are called pares curiæ; they inquire and make presentments of defaults and deaths of tenants, admittances, and surrenders in the lord's court, &c.

HOMALIUM, a genus of the class and order polyandria trigynia. The calyx is six or seven-parted: corolla, six or seven-petalled: stamina, 21 in three bodies: pericarpium, one-celled, many-seeded. There are two species, a tree of Jamaica and a shrub of Guiana.

HOMICIDE, properly so called, is the killing of a man by a man. Of this there are several species, as homicide by self-defence, homicide by misadventure, justifiable homicide, manslaughter, chance-medley, and murder.

Homicide by self-defence. Homicide se defendendo, or in a man's own defence, seems to be, where one has no other possible means of preserving his life from one who combats with him on a sudden quarrel, and kills the person by whom he is reduced to such inevitable necessity. 1 Haw. 75.

And not only he who on an assault retreats to a wall, or some such strait, beyond which he can go no farther before he kills the other, is judged by the law to act upon unavoidable necessity; but also he, who being assaulted in such a manner and in such a place, that he cannot go back without manifestly endangering his life, kills the other without retreating at all. Id.

And though a person who retreats from an assault to the wall should give the other wounds in his retreat, yet if he gives him no mortal wound till he gets thither, and then kills him, he is guilty of homicide se defendendo only. Id.

But if the mortal wound was given first, then it is manslaughter. Hale's Pl. 42.

Homicide by misadventure, is where a man in doing a lawful act without any intent of hurt, unfortunately chances to kill another, as where a labourer being at work with an hatchet, the head thereof flies off, and kills one who stands by. 1 Haw. 73.

It seems clear, that neither homicide by misadventure, nor homicide se defendendo are felonious, because they are not accompanied with a felonious intent, which is necessary in every felony. 1 Haw. 29.

Justifiable homicide. To make homicide justifiable, it must be owing to some unavoidable necessity, to which a person who kills another must be reduced, without any manner of fault in himself.

And there must be no malice coloured under pretence of necessity; for wherever a persons who kills another, acts in truth upon malice, and takes occasion upon the appearance of necessity to execute his own private revenge, he is guilty of murder. 1 Haw. 69.

But if a woman kills him who assaults to ravish her, it is no felony; or if a man comes to burn my house, and I go out thereof and kill him, it is no felony. Id. 39.

If any evil-disposed person shall attempt feloniously to rob or murder any person in any dwelling-house, or highway, or feloniously attempt to break any dwelling-house in the night time, and shall happen to be slain in such felonious attempt, the slayer shall be discharged, and shall forfeit no lands, nor goods. 24 H. VIII. c. 5.

Justifiable homicide of a public nature, is such as is occasioned by the due execution or advancement of public justice, with regard to which it must be observed.

1. That the judgment, by virtue whereof any person is put to death, must be given by one who has legal jurisdiction in the cause; for otherwise both judge and officer may be guilty of felony.

2. The execution must be pursuant to, and warranted by the judgment, otherwise it is without authority; and consequently, if a sheriff shall behead a man, when it is

no part of the sentence to cut off the head, he is guilty of felony. 1 Haw. 70.

Manslaughter. Homicide against the life of another, is either with or without malice; that which is without malice is called manslaughter, or sometimes chance medley, by which is understood such killing as happens either on a sudden quarrel, or in the commission of an unlawful act, without any deliberate intention of doing any mischief at all. 3 Inst. 56.

Hence it follows, that there can be no accessaries to this offence before the fact, because it must be done without premeditation; but there may be accessaries after the fact. Id.

The only difference between murder and manslaughter, is, that murder is upon malice aforethought, and manslaughter upon a sudden occasion, as if two meet together, and striving for the wall the one kills the other, this is manslaughter and felony. And so it is if they had, on that sudden occasion, gone into the field and fought, and the one had killed the other, this had been but manslaughter and no murder, because all that followed was but a continuance of the first sudden occasion, and the blood was never cooled till the blow was given. 3 Inst. 55.

Chance or chaunce-medley. Authors of the first authority disagree about the application of this word; by some it is applied to homicide by misadventure, by others to manslaughter. The original meaning of the word seems to favour the former opinion, as it signifies a sudden or casual meddling or contention; but homicide by misadventure supposes no previous meddling or falling out.

Murder is the highest crime against the law of nature that a man is capable of committing.

Murder is when a man of sound memory, and at the age of discretion, unlawfully kills another person under the king's peace with malice aforethought, either expressed by the party, or implied by the law, so as the party wounded or hurt die of the wound or hurt within a year and a day. 3 Inst. 47.

And the whole day on which the hurt was done, shall be reckoned the first. 1 Haw. 79.

By malice expressed, is meant a deliberate intention of doing any bodily harm to another, whereunto by law a person is not authorized.

And the evidences of such malice must arise from external circumstances discovering that inward intention; as lying in wait, menacings antecedent, former grudges, deliberate compassings and the like, which are various, according to the variety of circumstances. 1 H. H. 451.

Malice implied, is where a person voluntarily kills another, without any provocation; for in this case the law presumes it to be malicious, and that he is a public enemy of mankind. 1 H. H. 455.

In general any formed design of doing mischief may be called malice; and therefore not such killing only as proceeds from premeditated hatred or revenge against the person killed, but also in many other cases, such as is accompanied with circumstances which show the heart to be perversely wicked, is judged to be of malice prepense, or aforethought, and consequently murder. 2 Haw. 80.

If a man kills another, it shall be intended prima facie that he did it maliciously, unless he makes the contrary appear, by showing that he did it on a sudden provocation or the like. 1 Haw. 82.

When the law makes use of the term malice aforethought as descriptive of the crime of murder, it must not be understood in that narrow restrained sense, to which the modern use of the word malice is apt to lead one, a principle of malevolence to particulars; for the law by the term malice, in this instance, means, that the fact has been attended with such circumstances as are the ordinary symptoms of a wicked heart, regardless of social duty, and fatally bent upon mischief. Fost. 256.

The law so far abhors all duelling in cold blood, that not only the principal who actually kills the other, but also his seconds are guilty of murder, whether they fought or not; and it is holden that the seconds of the person killed are also equally guilty, in respect to that countenance which they give to their principals in the execution of their purpose, by accompanying them therein, and being ready to bear a part with them. 1 Haw. 82.

Also it seems agreed, that no breach of a man's word or promise, no tresspass either to land or goods, no affront by bare words or gestures, however false or malicious it may be, and aggravated with the most provoking circumstances, will excuse him from being guilty of murder who is so far transported thereby, as immediately to attack the person who offends, in such a manner as manifestly endangers his life, without giving him time to put himself upon his guard, if he kills him in pursuance of such assault, whether the person slain did at all fight in his defence or not. Id.

HOMINE REPLEGIANDO, in law, is an ancient writ that lies for bailing a person out of prison, where any one is confined without commandment of the king or his judges; or for any cause that is repleviable. This writ is directed to the sheriff, commanding him to replevy the prisoner. In case a person takes away secretly, or keeps in his custody any person against his will, on oath made thereof, and a petition to the lord chancellor, he will grant a writ of replegiari facias, upon which the sheriff returns an elongatus, and then there issues a capias in withernam, to take the party so offending.

HOMOGENEOUS SURDS, those which have the same radical character, or signs, as $\sqrt[2]{a}$ and $\sqrt[2]{b}$.

HOMOLOGOUS, in geometry, an appellation given to the corresponding sides and angles of similar figures, as being proportional to each other.

HOMOLOGOUS THINGS, in logic, those which agree in name, but are of different natures.

HONEY, a saccharine substance prepared by the bees (see APIS). It has a white or yellowish colour, a soft and grained consistence, a saccharine and aromatic smell. By distillation it affords an acid phlegm and an oil, and its coal is light and spongy like that of the mucilage of plants. Nitric acid extracts from it oxalic acid precisely as it does from sugar; it is very soluble in water, with which it forms a syrup, and like sugar passes to the vinous fermentation. Mr. Cavezzali has proved lately that honey is composed of sugar, mucilage, and an acid. The sugar may be separated by melting the honey, adding carbonat of lime in powder as long as any effervescence appears, and scumming the solution while hot. The liquid thus treated gradually deposits crystals of sugar when allowed to remain in a glass vessel. There are

three distinctions of honey, according to its purity, fluidity, and the manner in which it has been procured from the honey-combs. The first and finest kind is virgin-honey, or the first produce of a swarm, obtained from the combs without pressing; these being only set to drain, in order to its running out. The second kind is that known by the name of white-honey, being thicker than the former, and often indeed almost solid; it is procured by pressing the combs, but without the assistance of heat. The third and worst kind is the common yellow honey, obtained from the combs first heated over the fire, and then pressed.

Honey-comb, a waxen structure, full of cells, framed by the bees, to deposit their honey and eggs in.

The construction of the honey-comb seems one of the most surprising of the works of insects, and the materials of which it is composed, which, though evidently collected from the flowers of plants, yet do not, that we know of, exist in them in that state, has given great cause of speculation to the curious. The regular structure of the comb is also equally wonderful. When the several cells in it are examined, it should seem that the nicest rules of geometry had been consulted for its composition, and all the advantages that could be wished, or desired, in a thing of that kind, are evidently found in it. Each cell consists of six plane sides, which are all trapeziums, but equal to each other; the bottom of the cell is contrived with three rhombuses, H K D I, D E F I, and F G H I, (plate LXXII. Miscel. fig. 124) so disposed as to constitute a solid angle at I, under the three equal angles D I H, D I F, and H I F, each of which is double the maximum angle of $54^{\circ} 44' =$ D I K = D K I. Hence it comes to pass, that a less quantity of surface is sufficient to contain a given quantity of honey, than if the bottom had been flat, in the proportion of 4658 to 5550, as has been found by calculation; that is, nearly a fifth of the whole, so far as the figure in the end of the cells extends, in each; which fifth part of wax and labour saved, amounts to a vast deal in the whole comb. The sides of the cells are all much thinner than the finest paper, and yet they are so strengthened by their disposition, that they are able to resist all the motions of the bee within them, as they are frequently obliged to be. The effect of their thrusting their bodies into the cells would be the bursting of those cells at the top, was not this well-guarded against. But to prevent this, the creatures extend a cord, or roll of wax, round the verge of every cell, in such a manner that it is scarcely possible they should split in that particular part. This cord or roll is at least three times as thick as the sides of the cell, and is even much thicker and stronger at the angles of the cells, than elsewhere, so that the aperture of each cell is not regularly hexagonal, though its inner cavity is perfectly so. See fig. 125.

The several combs are all placed parallel to one another (fig. 126) and there is such a space left between them, that the bees can easily pass; and often they place a part of the comb in a contrary direction to the rest, so that while the others are placed horizontally, these stand perpendicularly.

The celerity with which a swarm of bees received into a hive, where they find themselves lodged to their minds, bring their works of the combs to perfection is amazing. There are vast numbers at work all at once; and that they may not incommode one another, they do not work upon the first comb till it is finished, but when the foundation of that is laid, they go to work upon another, so that there are often the beginnings of three or four stories made at once, and so many parties allotted to the carrying on the work of each. In a very few days a new swarm will have completed several combs of the depth of four or five inches each.

Honey-stone. See Melite.

HONOUR, is used for a seignory or lordship, on which inferior lordships and manors depend; for as a manor consists of several lands, tenements, services, and customs, so an honour contains several manors, knights-fees, &c.

Honour-courts, are courts held within the honours or seignories.

Honour, *maids of*, are six young ladies in the household of the queen, and princess royal; the salary of those of a queen are 300*l.* each, and those of the princess dowager of Wales, 200*l.*

Honour-point, in heraldry, is that next above the centre of the escutcheon, dividing the upper part into two equal portions.

HOOF, the horny substance that covers the feet of divers animals, as oxen, horse, sheep, &c. See Horn.

HOOPING-COUGH. See Medicine.

HOP. See Humulus.

HOPEA, a genus of the polyandria order, in the polyadelphia class of plants. The calyx is quinquefid, superior; the corolla pentapetalous; the stamina are many, and coalited into five pencils; there is one style; the fruit is a plum, with a trilocular kernel. There is only one species, the tinctoria, a native of Carolina.

HORARY, or Hour-circle. See *Use of the* Globe.

Horary circle, or lines. See Dialling.

Horary motion *of the earth*, the arch it describes in the space of an hour, which is nearly 15 degrees, though not accurately so, as the earth moves with different velocities, according to its greater or lesser distance from the sun.

HORDEUM, *barley*; a genus of the triandria-trigynia class of plants, the corolla whereof consist of two valves; the inferior valve is angular, of an ovato-accuminated figure, bellied, and longer than the cup, and terminates in a very long arista; the anterior valve is lanceolated, plane and smaller; the corolla serves as a pericarpium, surrounding the seed, and not letting it out; the seed is oblong, ventricose, pointed at each end, and marked with a longitudinal furrow. See Husbandry.

HORIA, in entomology, a genus of the coleoptera order. Antennæ, moniliform; feelers four, thicker towards the tip; lip linear, rounded at the end. There are two species; the testacea, and the dermestoides.

HORIZON. See Astonomy and Geography.

HORIZONTAL dial. See Dialling.

Horizontal line. See Perspective.

Horizontal plane, that which is parallel to the horizon of the place, or nothing inclined thereto. The business of levelling is to find whether two points are in the horizontal plane, or how much the deviation is.

Horizontal range *of a piece of ordnance*, is the distance at which it falls on or strikes the horizon, or on a horizontal plane, whatever is the angle of elevation or

direction of the piece. When the piece is pointed parallel to the horizon, the range is then called the point-blank, or point-blanc range.

The greatest horizontal range, in the parabolic theory, or in a vacuum, is that made with the piece elevated to 45 degrees, and is equal to double the height from which a heavy body must freely fall to acquire the velocity with which the shot is discharged. Thus, a shot being discharged with the velocity of v feet per second; because gravity generates the velocity $2g$ or $32\frac{1}{6}$ feet in the first second of time, by falling $16\frac{1}{12}$ or g feet, and because the spaces descended are as the squares of the velocities, therefore as $4g^2 : v^2 :: g \frac{v^2}{4g}$, the space a body must descend to acquire the velocity v of the shot or the space due to the velority v; consequently the double of this, or $\frac{x^2}{2g} = \frac{v^2}{32\frac{1}{6}}$ is the greatest horizontal range with the velocity v, or at an elevation of 45 degrees; which is nearly half the square of a quarter of the velocity.

In other elevations, the horizontal range is as the sine of double the angle of elevation; so that, any other elevation being e, it will be, as radius $1 : \sin. 2e :: \frac{v^2}{32\frac{1}{6}} : \frac{v^2}{32\frac{1}{6}} \times \sin. 2e$, the range; at the elevation e, with the velocity v.

But in a resisting medium, like the atmosphere, the actual ranges fall far short of the above theorems, insomuch that with the great velocities the actual or real ranges may be less than the tenth part of the potential ranges; so that some balls, which actually range but a mile or two, would in vacuo range 20 or 30 miles. And hence also it happens that the elevation of the piece, to shoot farthest in the resisting medium, is always below 45°, and gradually the more below it as the velocity is greater; so that the greater velocities with which balls are discharged from cannon with gunpowder, require an elevation of the gun equal to but about 30°, or even less. And the less the size of the balls is too, the less must this angle of elevation be to shoot the farthest with a given velocity. See PROJECTILE and GUNNERY.

HORN, *cornu*, in physiology, a hard substance growing on the heads of animals, particularly the cloven-footed quadrupeds; and serving them both as weapons of offence and defence.

Horns are not very hard, as they may be easily cut with a knife or rasped with a file; but they are so tough as not to be capable of being pounded in a mortar. When in thin plates, they have a degree of transparency, and have been sometimes substituted for glass in windows. When heated sufficiently, they become very soft and flexible, so that their shape may be altered considerably. Hence they may be gradually squeezed into a mould, and wrought into various forms, as is well known. The quantity of earthy matter which they contain is exceedingly small. Mr. Hatchett burnt 500 grains of ox-horn. The residuum was only 1.5 grain, and not the half of this was phosphat of lime. Seventy-eight grains of the horn of the chamois left only 0.5 of residue, of which less than the half was phosphat of lime. They consist chiefly of a membranous substance, which possesses the properties of coagulated albumen; and probably they contain also a little gelatine. Hence we see the reason of the products that are obtained when these substances are subjected to distillation.

The horns of the hart and buck must, however, be excepted. From the experiments of Scheele and Roulle, together with those of Hatchett, we know that these substances possess exactly the properties of bone, and are composed of the same constituents, excepting only that the proportion of cartilage is greater. They are intermediate, then, between bone and horn.

The nails, which cover the extremities of the fingers, are attached to the epidermis, and come off along with it. Mr. Hatchett has ascertained that they are composed chiefly of a membranous substance, which possesses the power of coagulated albumen. They seem to contain also a little phosphat of lime. Water softens, but does not dissolve them. But they are readily dissolved and decomposed by concentrated acids and alkalies. Hence it appears that nails agree with horns in their nature and composition. Under the head of nails must be comprehended the talons and claws of the inferior animals, and likewise their hoofs, which differ in no respect from horn.

The substance called tortoise-shell is very different from shells in its composition, and approaches much nearer to the nature of nail: for that reason we have placed it here. When long macerated in nitric acid, it softens, and appears to be composed of membranes laid over each other, and possessing the properties of coagulated albumen. When burnt, 500 grains of it yield three of earthy matter, consisting of phosphat of lime and soda, with a little iron.

The scales of animals are of two kinds: some, as those of serpents and other amphibious animals, have a striking resemblance to horn; while those of fish bear a greater resemblance to mother-of-pearl. The composition of these two kinds of shells is very different.

The scales of fish, as has been observed by Lewenhoeck, are composed of different membranous laminæ. When immersed for four or five hours in nitric acid, they become transparent, and perfectly membranaceous. The acid, when saturated with ammonia, gives a copious precipitate of phosphate of lime. Hence they are composed of alternate layers of membrane and phosphat of lime. To this structure they owe their brilliancy. Mr. Hatchett found the spicula of the shark's skin to be similar in its composition, but the skin itself yielded no phosphat of lime.

The horny scales of serpents, on the other hand, are composed alone of a horny membrane, and are destitute of phosphat of lime. They yield, when boiled, but slight traces of gelatine: the horn-like crust which cover certain insects and other animals appear from Mr. Hatchett's experiments to be nearly similar in their composition and nature.

The casting of the horns of deer is a singular phænomenon, the true reason of which seems to be a stoppage of the circulation; so that being deprived of the nourishing juice, they fall off much in the same manner as the leaves of trees in autumn. About ten days after the horns are cast, the new ones begin to appear: these at

first are soft and hairy, but they afterwards grow hard, and the creature rubs off the hair.

Horns make a considerable article in the arts and manufactures. Bullocks' horns, softened by the fire, serve to make lanthorns, combs, knives, ink-horns, tobacco-boxes, &c.

Dyeing of horns. Black is performed by steeping brass in aqua-fortis till it is turned green: with this the horn is to be washed once or twice, and then put into a warmed decoction of logwood and water. Green is begun by boiling it, &c. in alum-water, then with verdigris, ammoniac, and white-wine vinegar, keeping it hot therein till sufficiently green. Red is begun by boiling it in alum-water, and finished by decoction in a liquor compounded of quicklime steeped in rain-water, strained, and to every pint an ounce of Brazil wood added. In this decoction the bone, &c. is to be boiled till sufficiently red.

Dr. Lewis informs us, that horns receive a deep black stain from solution of silver. It ought to be diluted to such a degree as not sensibly to corrode the subject, and applied two or three times, if necessary, at considerable intervals, the matter being exposed as much as possible to the sun, to hasten the appearance and deepening of the colour.

Dyeing or staining horn to imitate tortoise-shell. The horn to be dyed must be first pressed into proper plates, scales, or other flat form, and the following mixture prepared: Take of quick-lime two parts, and of litharge one part: temper them together to the consistence of a soft-paste with soap ley. Put this paste over all the parts of the horn, except such as are proper to be left transparent, in order to give it a near resemblance of the tortoise-shell. The horn must remain in this manner covered with the paste till it is thoroughly dry; when, the paste being brushed off, the horn will be found partly opaque and partly transparent, in the manner of tortoise-shell, and when put over a foil of the kind of latten called assidue, will be scarcely distinguishable from it. It requires some degree of fancy and judgment to dispose of the paste in such a manner as to form a variety of transparent parts, of different magnitudes and figures, to look like the effect of nature: and it will be an improvement to add semitransparent parts, which may be done by mixing whiting with some of the paste to weaken its operation in particular places, by which spots of a reddish brown will be produced, which if properly interspersed, especially on the edges of the dark parts, will greatly increase both the beauty of the work and its similitude to real tortoise-shell.

Horn is also a musical intrument of the wind kind, chiefly used in hunting, to animate the hunters and the dogs, and to call the latter together. The French horn is bent into a circle, and goes two or three times round, growing gradually largar and wider towards the end, which in some horns is nine or ten inches over.

Horns *of insects*, the slender oblong bodies projected from the heads of those animals, and otherwise called antennæ or feelers. See Entomology.

HORNBLENDE. This mineral enters into the composition of many mountains. It is also amorphous, but frequently also crystallized. The primitive form of its crystals is a rhomboidal prism, the faces of which are inclined at angles of 124° 34′ and 55° 26′, and whose bases are angles of 122° 56′ and 57° 4′. The most common variety is a six-sided prism, terminated by trihedral or tetrahedral summits.

Hornblende, *common*. Its texture is very conspicuously foliated; fracture conchoidal; fragments often rhomboidal; opaque; tough; specific gravity 2.922 to 3.41; colour black, blackish-green, olive-green, or leek-green; streak greenish. It neither becomes electric by friction nor heat. Before the blow-pipe it melts into a black glass. A specimen of black hornblende, analysed by Mr. Hermann, was compossed of

37	silica
27	alumina
25	iron
5	line
3	magnesia
97	

Hornblende, *basaltic*. This stone is found commonly in basaltic rocks; hence the name *basaltine*, which was imposed by Mr. Kirwan. It is crystallized either in rhomboidal prisms, or six or eight-sided prisms, terminated by three-sided pyramids. Its texture is foliated; its fracture uneven; specific gravity 3.333; colour black, dark-green, or yellowish-green; streak white; transmits a reddish-yellow light. Before the blow-pipe it melts into a greyish-coloured enamel, with a tint of yellow. A specimen, seemingly of this stone, analysed by Bergman, contained

58	silica
27	alumina
9	iron
4	lime
1	magnesia
99	

Hornblende, *shistose*. Colour greenish-black or deep green; forms strata; structure shistose; texture radiated or fibrous; opaque; brittle; streak greenish grey; moderately heavy; gives an argillaceous smell when breathed upon. This mineral is often confounded with slate. In Sweden it is employed for covering houses.

HORNERS, those artificers whose business it is to prepare various utensils of the horns of cattle. The horners were a very ancient and considerably fraternity in the city of London some hundred years ago. In the reign of Edward II. they complained to parliament, that by foreigners buying up the horns in England, they were in danger of being ruined, and this business lost to the nation. For this reason was made the statute 6 Edw. IV. by which the sale of horns to foreigners (except such as the said horners refused) was prohibited; and the wardens had power granted them to search all the markets in London and 24 miles round, and to inspect Stourbridge and Ely fairs, to prevent such practices, and to purchase horns at stated prices. But on plausible pretences this law was repealed in the reign of James I. and thereupon the old evil revived. The horners again applied to parliament, and king Edward's statute was renewed (excepting as to the inspection of the fairs), and still remains in force. The importation of unwrought horns into that country is also prohibited. The present company of horners were incoporated January 12, 1638.

Horn-fish, a species of esox, otherwise called garfish. See Esox.

Horn-work, in fortification, an out-work composed of two demi-bastions, joined by a curtin. See Fortification.

HORNET, in zoology, a species of vespa with a black thorax, and double black spots on the segments of the body. See Vespa.

HORNSTONE, in mineralogy. This stone is usually amorphous, occurring sometimes in mass, and sometimes in round balls. Fracture splintery, and sometimes conchoidal; specific gravity 2.7; colour greyish-blue, but sometimes grey, red, blue, green, and brown, of different shades. According to Kirwan, it is composed of

72	silica
22	alumina
6	carbonat of lime
100	

HORSE. See Equus.

Horse-dealers. Every person exercising the trade or business of a horse-dealer, must take out a licence from the stamp-office, for which he shall pay annually, if within London, Westminster, the bills of mortality, the parish of Pancras, or the borough of Southwark, 20*l.*; elsewhere, 10*l.*

The commissioners are to grant licences to horse-dealers for not exceeding one year; and every license shall cease on September 29, then in the year for which the same shall be issued, and commence from the date; and every licence taken out for any year subsequent to the year in which the same shall be issued, shall commence from September 29, then next ensuing, and continue till September 29 following; and a fresh licence is to be taken out ten days at least before the expiration of the year.

One licence is sufficient for partners, and the licence is confined to the place mentioned thererein. But no licences to be granted to horse-dealers, unless they declare they seek their living by buying and selling horses, and add the name of the place where the said business is carried on. 29 Geo. III. c. 49.

Horse-dealers so licenced, shall cause the words *licenced to deal in horses* to be painted or written in large and legible characters either on a sign hung out or on some visible place in the front of their house, gate-way, or stables; and if they shall sell any horse without fixing such token, they shall forfeit 10*l.* to be recovered by action, half to the king, and half to the informer. 36 Geo. III. c. 17.

Horse-dealers who shall, after January 1, 1796, carry on the said business without having obtained a licence under this act, shall be liable to be assessed the duties on riding-horses, and shall deliver lists thereof as other persons.

Horse-shoe, in fortification, is a small work, sometimes of a round and sometimes of an oval figure, inclosed with a parapet, sometimes raised in the moat or ditch, or in low grounds, and sometimes to cover a gate, or to serve as a lodgment for soldiers. See Fortification.

Horse-shoes. See Farriery.

Horse, in a ship, is a rope made fast to each yard arm, and on which the men stand to furl the sails. It is also a wooden frame with a rowel fixed in it, made use of by the riggers to woold ships-masts.

HORSES. It shall be lawful for any person, native or foreigner, at any time to ship, lade, and transport by way of merchandize, horses into any parts beyond the seas in amity with his majesty, paying for each horse, mare, or gelding, 5*s.* and no more.

No person convicted for feloniously stealing a horse, gelding, or mare, shall have the privilege of clergy. 1 Edw. VI. c. 12. And not only all accessaries before such felony done, but also all accessaries after such felony, shall be deprived and put from all benefit of their clergy, as the principal, by statute heretofore made, is or ought to be.

If a horse be stolen out of the stable, or other curtilage of a dwelling-house, in the night time, it falls under the denomination of burglary; if in the day-time, it falls under the denomination of larceny from the house; and in either case there is a reward of 40*l.* for convicting an offender, and the prosecutor is entitled to a certificate which will exempt him from all parish and ward offices in the parish and ward where the burglary or larceny is committed, and which may be once assigned over, and will give the same exemption to the assignee as to the original proprietor. Burn's Just. 621.

If an unsound horse is sold at the price of a sound horse, though not absolutely warranted to be sound, the seller sins against the law of morality and the law of the land; but if he acknowledges him not to be sound, and sells him greatly under the value of a sound horse, as if he disposes of him for 25*l.* when he would have been worth 50*l.* if sound, such sale may be considered as fair and legal.

If a horse which is warranted sound at the time of sale is proved to have been at that time unsound, it is not necessary that he should be returned to the seller. No lapse of time elapsed after the sale will alter the nature of a contract originally false. Neither is notice necessary to be given; though the not giving notice will be a strong presumption against the buyer, that the horse at the time of sale had not the defect complained of, and will make the proof on his part much more difficult. The bargain is complete; and if it is fraudulent on the part of the seller, he will be liable to the buyer in damages, without either a return or notice.

If on account of a horse warranted sound, the buyer shall sell him again at a loss, an action might *perhaps* be maintained against the original seller, to recover the difference of the price. 1 Hen. Black. 17.

Slaughtering horses. Great abuses having arisen, and many horses having been stolen, from the facility and safety of disposing of them to those who keep slaughter-houses for horses, some regulations and restrictions seemed abolutely necessary. It was no uncommon thing for horses of great value to be sold for the purpose of making food for dogs; the thief rather choosing to receive 20*s.* for a stolen horse, without fear or danger of detection, than venture to dispose of him publicly, though he might possibly have found a purchaser who would have given as many pounds for him. These considerations induced the legislature to pass the act of 26 Geo. III. c. 71, for regulating these slaughter-houses.

Killing or maiming horses. Where any person shall in

the night-time maliciously, unlawfully, and willingly kill or destroy any horses, sheep, or other cattle, of any person, every such offence shall be adjudged felony, and the offender shall suffer as in the case of felony. 22 and 23 Car. II. c. 7.

Offenders may be transported for seven years, either at the assizes or at the sessions, by three justices of the peace, one to be of the quorum.

By the 9th Geo. I. c. 22. commonly called the black-act, it is enacted, that if any person shall unlawfully and maliciously kill, maim, or wound any cattle, every person so offending, being thereof lawfully convicted in any county of England, shall be adjudged guilty of felony, and shall suffer death, as in cases of felony, without benefit of clergy. But not to work corruption of blood, loss of dower, nor forfeiture of lands or goods.

Prosecution upon this statute shall or may be commenced within three years from the time of the offence committed, but not after.

If an horse or other goods are delivered to an innkeeper or his servants, he is bound to keep them safely, and restore them when his guest leaves the house. 2 Black. 451.

If an horse is delivered to an agisting farmer, for the purpose of depasturing in his meadows, he is answerable for the loss of the horse, if it is occasioned by the ordinary neglect of himself or his servants. Jones on Bailm. 91.

If a man rides to an inn, where his horse has eaten, the host may detain the horse till he is satisfied for the eating, and without making any demand. 14 Vin. Abr. 437. But an horse committed to an inn-keeper can only be detained for his own meat, and not for that of his guest or any other horse; for the chattels in such case are only in the custody of the law for the debt which arises from the thing itself, and not for any other debt due from the same party. 2 Rol. Abr. 85.

By the custom of London and Exeter, if a man commits an horse to an inn-keeper, if he eats out his price, the inn-keeper may take him as his own, upon the reasonable appraisement of four of his neighbours; which was it seems a custom arising from the abundance of traffic with strangers, that could not be known so as to be charged with an action. But it has been holden, though an inn-keeper in London may, after long keeping, have the horse appraised and sell him, yet, when he has in such case had him appraised, he cannot justify the taking him to himself at the price he was apprised at. Vin. Abr. 233.

HORTUS siccus, a *dry garden*, an appellation given to a collection of specimens of plants, carefully dried and preserved. The value of such a collection is very evident, since a thousand minutiæ may be preserved in the well-dried specimens of plants, which the most accurate engraver would have omitted.

Among the different methods adopted by botanists for obtaining a hortus siccus, the following appear to be the most practicable:

1. Lay the plants flat between papers; then place them between two smooth plates of iron screwed together at the corners: in this state they are to be committed to a baker's oven for two hours. After being taken out, they must be rubbed over with a mixture, consisting of equal parts of brandy and vinegar, then pasted down on paper with a solution of gum-tragacanth in water, after which they are to be laid in a book, where they will adhere, and retain ther original freshness. The following method is however more simple.

2. Flatten the plant by passing a common smoothing-iron over the papers between which it is placed, and dry it slowly in a sand-heat. For this purpose the cold sand ought to be spread evenly, the smoothened plant laid gently on it, and sand sifted over so as to form a thick bed; the fire is then to be kindled, and the whole process carefully watched, till the plant is gradually and perfectly dried. Thus the colour of the tenderest herb, may be preserved, and the most delicate flowers retain all their pristine beauty.

3. Another and far more complete method was suggested by the ingenious Mr. Whately. He directs those who intend to follow his plan, previously to procure—1. A strong oak-box of the same size and shape as those employed for packing up tin plates; 2. a quantity of fine sifted sand, sufficient to fill the box; 3, a considerable number of pieces of pliant paper, from one to four inches square; and 4. some small flat leaden weights, and a few small bound books.

The plant is first to be cleared from the soil as well as the decayed leaves, and then laid on the inside of one of the leaves of a sheet of common cap-paper. The upper leaves and flowers are next to be covered, when expanded, by pieces of the prepared paper, and one or two of the leaden weights placed on them. The remainder of the plant is now to be treated in a similar manner.

The weights ought next to be gently removed, and the other leaf of the sheet of paper folded over the opposite one so as to contain the loose pieces of paper and plants between them. A book or two is now to be applied to the outside of the paper till the intended number of plants is thus prepared; when a box is to be filled with sand to the depth of an inch, one of the plants put in, and covered with sand sufficient to prevent the form of the plant from varying. The other plants may then be placed in succession, and likewise covered with a layer of sand, one inch thick between each; after which the whole is to be gently pressed down in a greater or less degree, according to the tenderness or firmness of the plants.

The box is next to be carefully placed before a fire, one side being occasionally a little raised, as may be most convenient; the sides being alternately presented to the fire two or three times in the day, or the whole may be put into an oven gently heated. In the course of two or three days the plants will be perfectly dry, when the sand ought to be taken out and put into another box: the plants should likewise be removed to a sheet of writing paper.

HOSPITALERS, an order of religious knights, now known by the title of knights of Malta.

HOT-BEDS, in gardening, beds made with fresh horse-dung, or tanner's bark, and covered with glasses to defend them from cold winds.

According to the quantity and quality of the materals put together for hot beds, the heat will be proportioned as to strength and duration; and by a judicious use in making, and the management afterwards, many advantages may be obtained from them. The great point is, to suit the degree of heat to the nature of the different

plants to be cultivated, that they may have neither more nor less than is necessary to promote a regular vegetation.

Two errors are common in the use of hot-beds, sowing or placing in the same bed things of a very different nature, as to the climate they grow best in, and forcing with too much heat even the tenderest. Though it may not answer our often too hasty views, the heat of a bed had better be slack than otherwise. A strong hot-bed that ought at least to be made a fortnight before it is used, is sometimes furnished by impatience in a few days, and various ill consequences follow, which naturally frustrate expectation.

The place where hot-beds are worked should be open to the full sun, catching it as early as possible in the morning, and having it as long as can be in the evening; and if not naturally sheltered, it should be screened from the north and nort-east winds by a bordered fence or rather one of reeds, as from a solid fence the wind reverberates; but straw or flake-hurdles set endwise may do. A screen of some sort (and a close-clipt hedge is as good as any) not only protects the inclosure from the harsher winds, and confines the warm air, but keeps a rather unsightly work from view, and straws from blowing about, the litter of which is so disagreeable.

Working of the dung is necessary previous to the making of a hot-bed, *i. e.* it should be thrown together on an heap, in a conical form; and when it has taken a thorough heat, and has been smoking or sweating for two or three days, it should be turned over, moving the outside in, or mixing the colder parts with the hot. When it has taken heat again for two or three days, give it a second turn as before, and having lain the same time, it will be in proper order for making a good lasting bed with a steady heat. If in haste, it may be made into a bed after the first heating; but it will be better for shifting again, or even a third time. When dung is ready before wanted, keep turning it over, lest it should be too much spent. It will be proper to begin to work fresh dung a week or ten days before it is used; but if the dung is not fresh, it is only necessary to throw it together for once heating.

The size of a hot-bed, as to length and breadth, is of course to be according to the frame; and the height of it according to the season and the degree of heat requisite to the nature of the plant to be cultivated. In a dry soil, a bed may be sunk in the ground from six inches to a foot, to make it more convenient to get at and manage. But beds made forward in the season should rather be on the surface, for the sake of being able to add stronger linings, &c.

In case of an insufficient quantity of good horse-dung, that of cows, oxen, or pigs, if it is strawy, and not too wet, may be mixed with it, in the proportion of one-fourth or more, especially in an advanced part of the season, or to cultivate things that are only forcing, and do not naturally require heat.

When the season is pretty much advanced, hot-beds may be made of grass mowings (as from an orchard) and weeds, which is a common practice in the cyder countries. These heats, however, are often too violent, and last not long; yet they may be lined with the same materials if done in time, otherwise if a green hot-bed gets greatly cool, it will not be recovered. A grass bed may be used as soon as warm, but let it not be overweighted by putting on heavy frames, or more mould than necessary. It should rather be worked with hand-glasses or oiled paper covers.

Hot-beds are sometimes made of the refuse bark of a tanner's yard, and also of oak-leaves; but these must have walled pits for them of a large size, and are seldom used but in hot-houses. A bark-bed properly made, and managed by forking up at two or three month's end, &c. will hold a fair, moderate, and steady heat four, five, or six months.

To decrease the heat of a bed, several holes may be made in it, by thrusting an iron bar, or a thick smooth sharp-pointed stake, up to the middle, which holes are to be close stopt again with dung or hay when the heat is sufficiently abated.

The uses to which hot-beds may be applied are various, but chiefly for the cultivation of cucumbers and melons. At the spring of the year, hot-beds are commonly made use of for forcing crops of several vegetables, as radishes, carrots, cauliflowers, lettuces, potatoes, turneps, kidney-beans, parslane, tarragon, small sallading, &c. Fruits of several sorts, strawberries, raspberries, &c. are sometimes brought forward by dung heat; as also various shrubs and flowers, by means of forcing-frames. Tender annuals, as balsams and other flowers that necessarily require heat to bring them up, and the less tender, and some even of the hardy sorts, are also cultivated on hot-beds, or by other assistance from dung, to produce an earlier blow than could otherwise be had.

Hot-house, in salt-making, the place where they dry the salt, when taken out of the boiling-pan. It is situated near the furnace, which, by means of funnels or tubes, conveys the heat into it.

Hot-house, in gardening, an erection intended for the culture of the tender exotics of tropical climates. It is usually built lower than a greenhouse, with double flues, and a pit in the middle for tanner's bark, in which, as in a kind of hot-bed, the pots containing the plants are to be plunged. A hot-house should be kept at a regular heat, seldom less than 70°; and when the weather becomes about 10° below that extremity, the fires may be left off. The tan should be renewed twice a year, in spring and autumn; and care must be taken not to plunge the plants in it till the heat is risen to a proper degree.

The ingenious Dr. Anderson, so well known for his labours in agriculture, has lately constructed a hot-house to be kept warm by air chiefly warmed by the heat of the sun. It is entirely of glass, and the upper part is a close chamber to contain the heated air, which is let into the house by a valve. In the winter the chamber is heated by a lamp, and the warm air is admitted in the same manner as that which is warmed by the sun. The house is also moveable; but for further details we must refer to the doctor's Agricultural Recreations.

HOTCH-pot, in law, is used for mixing of lands given in marriage with other lands in fee which fall by descent; as where a man possessed of thirty acres of land has issue only two daughters, and after his having given with one of them ten acres in marriage, he dies possessed of the other twenty. Here she that is thus married, in order to gain her share of the rest of the land, must put

her part given in marriage in hotch-pot; that is, she must refuse to take the sole profits of her lands, and cause it to be mingled with the other, so that an equal division may be made of the whole between her and her sister; by which means, instead of only her ten acres, she has fifteen.

HOVENIA, a genus of the class and order pentandria monogynia. The petals are five, convoluted; stigma trifid; capsule three-celled, three-valved. There is one species, a shrub of Japan.

HOVERING. Ships of 50 tons, laden with customable or prohibited goods, hovering on the coasts of this kingdom, within the limits of any port (and not proceeding from foreign parts), may be entered by officers of the customs, who are to take an account of the lading, and to demand and take a security from the master, by his bond to his majesty, in such sum of money as shall be treble the value of such foreign goods then on board; that such ship shall proceed (as soon as wind and weather and the condition of the ship will permit) on her voyage to foreign parts, and shall land the goods in some foreign port; the master refusing to enter into such bond on demand, or who having given bond, shall not proceed on such voyage (unless otherwise suffered to make a longer stay by the collector or other principal officer of such port where the vessel shall be, not exceeding 20 days); in either of the said cases, all the foreign goods may be taken out by the customhouse-officers, by direction of the collector, and properly secured; and if they are customable, the duties shall be paid; and if prohibited, they shall be forfeited.

The officers of the customs may prosecute the same, as also the ship, if liable to condemnation. 3 Geo. III. c. 21.

Commanders of men of war, and customhouse-officers, may compel ships of 50 tons, or under, hovering within two leagues of shore, to come into port. 6 Geo. I. c. 21.

If any ship or vessel shall be found at anchor, or hovering within eight leagues of the coast (except between the North Foreland and Beachy Head), unless by distress of weather, having on board foreign spirits, in any vessel or cask which shall not contain 60 gallons at least, or any wine in casks (provided such vessel shall have wine on board), shall not exceed 60 tons burthen, or six pounds weight of tea, or 20 pounds weight of coffee, or any goods whatever liable to forfeiture upon importation, that such goods, with the ship and furniture, shall be forfeited; spirits for the use of seamen, not exceeding two gallons per man, excepted. 42 Geo. III. c. 82.

HOUND. See CANIS.

HOUR, *hora*, in chronology, an aliquot part of a natural day, usually a 24th, sometimes a 12th. See ASTRONOMY, GEOGRAPHY, &c.

There are different hours used by chronologers, astronomers, dialists, &c. Sometimes hours are divided into equal and unequal. Equal hours are the 24th part of a day and night precisely, that is, the time wherein 15 degrees of the equator mount above the horizon. These are also called equinoctial hours, because they are measured on the equinoctial; and astronomical, because used by astronomers. They are also differently denominated according to the manner of accounting them in different countries. Astronomical hours are equal hours, reckoned from noon or mid-day, in a continued series of twenty-four. Babylonish hours are equal hours reckoned in the same manner from sun-rise. The Italian hours are also equal hours, reckoned in the same manner too, from sun-setting. European hours are also equal hours, reckoned from midnight; 12 from thence to noon, and 12 more from noon to midnight. Jewish, or planetary, or ancient hours, are the twelfth part of the artificial day and night, each being divided into 12 equal parts. Hence, as it is only in the time of the equinoxes that the artificial day is equal to the night, it is then only that the hours of the day are equal to those of the night. At other times they will be always either increasing or decreasing: and they will be the more or less unequal according to the obliquity of the sphere.

HOUSE. Every man's house is as his castle, as well to defend him against injuries, as for his repose.

Upon recovery in any real action or ejectment, the sheriff may break the house and deliver seisin, &c. to the plaintiff, the writ being habere facias seisinam, or possessionem; and after judgment it is not the house of the defendant in right and judgment of the law.

In all cases where the king is party, the sheriff, if no door is open, may break the party's house to take him, or to execute other process of the king, if he cannot otherwise enter; but he ought first to signify the cause of his coming, and request the door to be opened: and this appears by the statute Westm. 1, 17, which is only in affirmance of the common law; and without default in the owner, the law will not suffer an house to be broken.

In all cases where the door is open, the sheriff may enter and make execution at the suit of any subject, either of body or goods; but otherwise where the door is shut, there he cannot break it to execute process at the suit of a subject.

Though an house is a castle for the owner himself and his family, and his own goods, &c. yet it is no protection for a stranger flying thither, or the goods of such a one, to prevent lawful execution; and therefore in such case, after request to enter, and denial, the sheriff may break the house. 5 Rep. 91.

If a person authorized to arrest another who is sheltered in an house, is denied quietly to enter into it, in order to take him, it seems generally to be agreed, that he may justify the breaking open of the doors upon a capias from the king's bench or chancery, to compel a man to find sureties for the peace or good behaviour, or even upon a warrant from a justice of the peace for such person.

So where one known to have committed treason, is pursued either with or without a warrant, by a constable or private person.

So where an affray is made in an house in the view or hearing of a constable; or where those who have made an affray in his presence fly to an house, and are immediately pursued by him, and he is not suffered to enter in order to suppress the affray in the first case, or to apprehend the affrayers in either case. 2 Haw. 86, 87.

A man ought so to use his house as not to damnify his neighbour: and a man may compel another to repair his house in several cases by the writ de domo reparanda. 1 Salk. 360.

If a man builds his house so close to mine, that his roof overhangs my roof, and throws the water of his

roof upon mine, this is a nuisance for which an action will lie.

But depriving one of a mere matter of pleasure, as of a fine prospect, by building a wall or the like; this, as it abridges nothing really convenient or necessary, is no injury to the sufferer, and is therefore not an actionable nuisance. 3 Black. 217.

HOUSEHOLD, the whole of a family considered collectively, including the mistress, children, and servants: but the household of a sovereign prince includes only the officers and domestics belonging to his palace.

The principal officers of his majesty's household are, the lord steward, lord chamberlain of the household, the groom of the stole, the master of the great wardrobe, and the master of the horse. The civil government of the king's house is under the care of the lord steward of the king's household, who, as he is the chief officer, all his commands are observed and obeyed. His authority extends over all the other officers and servants, except those of his majesty's chapel, chamber, and stable; and he is the judge of all crimes committed either within the court or the verge. Under him are the treasurer of the household, the comptroller, cofferer, the master of the household, the clerks of the green cloth, and the officers and servants belonging to the accounting-house, the marshalsea, the verge, the king's kitchen, the household kitchen, the acatery, bakehouse, pantry, buttery, cellar, pastry, &c. Next to the lord steward is the lord chamberlain of the household, who has under him the vice-chamberlain, the treasurer, and comptroller of the chamber, 12 of whom wait quarterly, and two of them lie every night in the privy chamber; the gentleman usher, the grooms of the great chamber, the pages of the presence chamber; the mace-bearers, cup-bearers, carvers, musicians, &c.

The groom of the stole has under him the eleven other lords of the bed-chamber, who wait weekly in the bed-chamber, and by turns lie there a-nights on a pallat-bed; and also the grooms of the bed-chamber, the pages of the bed-chamber and back stairs, &c.

The master or keeper of the great wardrobe has under him a deputy, comptroller, clerk of the robes, brusher, &c. and a number of tradesmen and artificers, who are all sworn servants to the king.

The master of the horse has under his command the equerries, pages, footmen, grooms, coachmen, farriers, saddlers, and all the other officers and tradesmen employed in his majesty's stables.

Next to the civil list of the king's court is the military, consisting of the band of gentlemen pensioners, the yeomen of the guard, and the troops of the household; of which the two first guard the king above stairs.

When the king dines in public, he is waited upon at table by his majesty's cup bearers, carvers, and gentlemen sewers, the musicians playing all the time. The dinner is brought up by the yeomen of the guard, and the gentlemen sewers set the dishes in order. The carvers cut for the king, and the cup-bearers serve him the drink with one knee on the ground, after he has first tasted it in the cover.

HOUSTONIA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 47th order, stellatæ. The corolla is monopetalous and funnel-shaped; the capsule bilocular, dispermous, superior. There are two species, shrubs of America.

HOUTTYNIA, a genus of the class and order polyandria polygynia. The calyx is four-leaved; corolla none, stamina mixed with the pistils, seven about each germ. There is one species, an herb of the East Indies, having the habit of a polygonum.

HUDSONIA, a genus of the monogynia order, in the dodecandria class of plants. There is no corolla: the calyx is pentaphyllous and tubular; there are 15 stamina; the capsule is unilocular, trivalvular, and trispermous. There is one species, a shrub of Virginia.

HUE AND CRY, is the ancient common law process after felons, and such as have dangerously wounded any person, or assaulted any one with an intent to rob him; and it has received great countenance and authority by several acts of parliament. In any of which cases, the party grieved, or any other, may resort to the constable of the vill; and, 1. give him such reasonable assurances thereof as the nature of the case will bear: 2. if he knows the name of him that did it, he must tell the constable the same: 3. if he knows it not, but can describe him, he must describe him, his person, or his habit, or his house or such circumstances as he knows, which may conduce to the discovery: 4. if the thing is done in the night, so that he knows none of these circumstances, he must mention the number of persons, or the way they took: 5. if none of all these can be discovered, as where a robbery, or burglary, or other felony, is committed in the night, yet they are to acquaint the constable with the fact, and desire him to search his town for suspected persons, and to make hue and cry after such as may probably be suspected, as being persons vagrant in the same night; for many circumstances may happen to be useful for discovering a malefactor, which cannot at first be found out.

For the levying of hue and cry, although it is a good course to have a justice's warrant, where time will permit, in order to prevent causeless hue and cry; yet it is not necessary nor always convenient, for the felon may escape before the warrant is obtained. And upon hue and cry levied against any person; or where any hue and cry comes to a constable, whether the person is certain or uncertain, the constable may search suspected places within his vill, for the apprehending of a felon. And if the person against whom the hue and cry is raised, is not found in the constablewick, then the constable, and also every officer to whom the hue and cry shall afterwards come, ought to give notice to every town round about him, and to one next town only; and so from one constable to another, until the offender is found, or till they come to the sea-side. And this was the law before the conquest.

And in such cases it is needful to give notice in writing to the pursuers of the thing stolen, and of the colour and marks thereof, as also to describe the person of the felon, his apparel, horse, or the like, and which way he is gone, if it may be: but if the person that did the fact is neither known nor describable by his person, clothes, or the like, yet such a hue and cry is good, and must be pursued, though no person certain can be named or described. 2 H. H. 100. 103.

HUER, a name given to certain fountains in Iceland, of a most extraordinary nature, forming at times jets d'eaux of scalding water 94 feet high and 30 in diameter. They arise out of cylindrical tubes of unknown depths. Near the surface they expand into apertures of a funnel shape, and the mouths spread into a large extent of stalactical matter, formed of successive scaly concentric undulations. The playing of these stupendous spouts is foretold by noises roaring like the cataract of of Niagara. The cylinder begins to fill: it rises gradually to the surface, and as gradually increases its height, smoking amazingly, and flinging up great stones. After attaining its greatest height, it gradually sinks till it totally disappears. Boiling jets d'eaux and boiling springs are frequent in most parts of the island; and in many parts they are commonly applied to the culinary uses of the natives. The most capital is that which is called geyer or geyser, in a plain rising into small hills, and in the midst of an amphitheatre, bounded by the most magnificent and various-shaped icy mountains, among which the three-headed Hecla soars pre-eminent. These huers are not confined to the land; they rise in the very sea, and form scalding fountains amidst the waves. Their distance from the land is unknown; but the new volcanic isle, twelve miles off the point of Reickness, emitting fire and smoke, proves that the subterraneous fires and waters extend to that space; for those awful effects arise from the united fury of these two elements.

HUGONIA, a genus of the decandria order, in the monadelphia class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous; the fruit is a plum with a striated kernel. There is one species, a tree of the East Indies.

HUGUENOTS, a name given by way of contempt to the protestants of France. The name had its rise in the year 1560; but authors are not agreed as to its origin. The most plausible opinion, however, is that of Pasquier, who observes, that at Tours, the place where they were first thus denominated, the people had a notion that an apparition or hobgoblin, called king Hugon, strolled about the streets in the night-time; whence as those of the reformed religion met chiefly in the night to pray, &c. they called them Huguenots, that is, the disciples of king Hugon.

HULL, in the sea language, is the main body of a ship, without either masts, yards, sails, or rigging. Thus to strike a hull in a storm is to take in her sails, and to lash the helm on the lee-side of the ship; and to hull or lie a hull, is said of a ship whose sails are thus taken in, and helm lashed a-lee.

HUMERUS. See ANATOMY.

HUMERUS, *luxation of the*. See SURGERY.

HUMMING-BIRD. See TROCHILUS.

HUMULUS, *the hop*, a genus of the pentandria order, in the diœcia class of plants, and in the natural method ranking under the 53d order, scabridæ. The male calyx is pentaphyllous; there is no corolla: the female calyx is monophyllous, patent obliquely, and entire; there is no corolla, but two styles, and one seed within the calyx, the latter consisting of one large leaf. There is only one species, viz. the lupulus, which is sometimes found wild in hedges near houses and gardens, but probably is not indigenous. The stalk is weak and climbing; it creeps up the support in a spiral, ascending always from the right hand to the left.

Hops are said to have been first brought into England from the Netherlands in the year 1524. They are first mentioned in the English statute-book in the year 1552, viz. in the 5th and 6th Edw. VI. cap. 5.: and by an act of parliament of the first year of king James I. anno 1603, cap. 18. it appears that hops were then produced in abundance in England. The hop being a plant of great importance, we shall consider what relates to the culture and management of it under distinct heads.

Of soil. As for the choice of soil, the hop-planters esteem the richest and strongest ground the most proper; and if it is rocky within two or three feet of the surface, the hops will prosper well; but they will by no means thrive on a stiff clay or spongy wet land.

The Kentish planters account new land best for hops; they plant their hop gardens with apple-trees at a large distance, and with cherry-trees between; and when the land has done its best for hops, which they reckon it will in about ten years, the trees may begin to bear.

To plant hops. In the winter time provide your soil and manure for the hop-ground against the following spring. If the dung is rotten, mix it with two or three parts of common earth, and let it incorporate together till you have occasion to make use of it in making your hop-hills; but if it is new dung, then let it be mixed as before till the spring in the next year, for new dung is very injurious to hops.

Hops require to be planted in a situation so open as that the air may freely pass round and between them, to dry up and dissipate the moisture, whereby they will not be so subject to fire-blasts, which often destroy the middles of large plantations, while the outsides remain unhurt.

The hills should be eight or nine feet asunder, that the air may freely pass between them. If the ground is intended to be ploughed with horses between the hills, it will be best to plant them in squares chequerwise; but if the ground is so small that it may be done with the breast-plough or spade, the holes should be ranged in a quincunx form. Which way soever you make use of, a stake should be stuck down at all the places where the hills are to be made.

Persons ought to be very curious in the choice of the plants as to the kind of hop; for if the hop garden is planted with a mixture of several sorts of hops that ripen at several times, it will cause a great deal of trouble, and be a great detriment to the owner. The two best sorts are the white and the grey bind; the latter is a large square hop, more hardy, and is the more plentiful bearer, and ripens later than the former. There is another sort of the white bind, which ripens a week or ten days before the common; but this is tenderer, and a less plentiful bearer; but it has this advantage, that it comes first to market.

If there is a sort of hop you value, and would increase plants and sets from, the superfluous binds may be laid down when the hops are tied, cutting off the tops, and burying them in the hill; or when the hops are dressed, all the cuttings may be saved; for almost every part will grow, and become a good set the next spring.

As to the seasons of planting hops, the Kentish planters approve the months of October and March. The most usual time, however, of procuring them is in March, when the hops are cut and dressed.

As to the manner of planting the sets, there should be five good sets planted in every hill, one in the middle, and the rest round about sloping. Let them be pressed close with the hand, and covered with fine earth, and a stick should be placed on each side the hill to secure it.

Dressing. As to the dressing of the hops, when the hop-ground is dug in January or February, the earth about the hills, and very near them, ought to be taken away with a spade, that you may come the more conveniently at the stock to cut it. About the end of February, if the hops were planted the spring before, or if the ground is weak, they ought to be dressed in dry weather; but else, if the ground is strong and in perfection, the middle of March will be a good time; and the latter end of March, if it is apt to produce over-rank binds, or the beginning of April may be soon enough. Then having with an iron picker cleared away all the earth out of the hills, so as to clear the stock to the principal roots, with a sharp knife you must cut off all the shoots which grew up with the binds the last year; and also all the young suckers, that none be left to run in the alley, and weaken the hill. It will be proper to cut one part of the stock lower than the other, and also to cut that part low that was left highest the preceding year. In dressing those hops that have been planted the year before, you ought to cut off both the dead tops and the young suckers which have sprung up from the sets, and also to cover the stocks with fine earth a finger's length in thickness.

The poling. About the middle of April the hops are to be poled, when the shoots begin to sprout up; the poles must be set to the hills deep into the ground, with a square iron picker or crow, that they may the better endure the winds; three poles are sufficient for one hill. These should be placed as near the hill as may be, with their bending tops turned outwards from the hill to prevent the binds from entangling; and a space between two poles ought to be left open to the south to admit the sunbeams.

The tying. As to the tying of hops, the buds that do not clasp of themselves to the nearest pole when they are grown to three or four feet high, must be guided to it by the hand, turning them to the sun, whose course they will always follow. They must be bound with withered rushes, but not so close as to hinder them from climbing up the pole. This you must continue to do till all the poles are furnished with binds, of which two or three are enough for a pole; and all the sprouts and binds that you have no occasion for, are to be plucked up; but if the ground is young, then none of these useless binds should be plucked up, but should be wrapped up together in the middle of the hill.

Gathering. About the beginning of July hops begin to blow, and will be ready to gather about Bartholomew-tide. A judgment may be made of their ripeness by their strong scent, their hardness, and the brownish colour of their seed. When by these tokens they appear to be ripe, they must be picked with all the expedition possible; for if at this time a storm of wind should come, it would do them great damage by breaking the branches, and bruising and discolouring the hops; and it is very well known that hops, being picked green and bright, will sell for a third more than those which are discoloured and brown.

The most convenient way of picking them is into a long square frame of wood, called a bin, with a cloth hanging on tenter-hooks within it, to receive the hops as they are picked.

The hops must be picked very clean, *i. e.* free from leaves and stalks; and, as there shall be occasion, two or three times in a day the bin must be emptied into a hop-bag made of coarse linen cloth, and carried immediately to the oast or kiln in order to be dried; for if they should be long in the bin or bag, they will be apt to heat and be discoloured. If the weather is hot, there should no more poles be drawn than can be picked in an hour, and they should be gathered in fair weather, if it can be, and when the hops are dry; this will save some expense in firing, and preserve their colour better when they are dried.

Drying. The best method of drying hops is with charcoal on an oast or kiln, covered with hair-cloth, of the same form and fashion that is used for drying malt. There is no need to give any particular directions for making these, since every carpenter or brick-layer in those countries where hops grow, or malt is made, knows how to build them. The kiln ought to be square, and may be of ten, twelve, fourteen, or sixteen feet over at the top, where the hops are laid, as your plantation requires, and your room will allow. There ought to be a due proportion between the height and breadth of the kiln and the beguels of the steddle where the fire is kept, viz. if the kiln is twelve feet square on the top, it ought to be nine feet high from the fire, and the steddle ought to be six feet and a half square, and so proportionable in other dimensions.

The hops must be spread even upon the oast a foot thick or more, if the depth of the curb will allow it; but care is to be taken not to overload the oast if the hops are green or wet. The oast ought to be first warmed with a fire before the hops are laid on, and then an even steady fire must be kept under them; it must not be too fierce at first, lest it scorch the hops, nor must it be suffered to sink or slacken, but rather be increased till the hops are nearly dried, lest the moisture or sweat which the fire has raised fall back or discolour them. When they have lain about nine hours they must be turned, and in two or three hours more they may be taken off the oast. It may be known when they are well dried by the brittleness of the stalks and the easy falling off the hop-leaves.

Bagging. As soon as the hops are taken off the kiln, lay them in a room for three weeks or a month to cool, give, and toughen; for if they are bagged immediately they will powder, but if they lie a while (and the longer they lie the better, provided they are covered close with blankets to secure them from the air) they may be bagged with more safety, as not being liable to be broken to powder in treading; and this will make them bear treading the better, and the harder they are trodden the better they will keep.

Laws relating to hops. By 9 Anne, cap. 121, an additional duty of 3*d.* a pound is laid on all hops imported, over and above all other duties; and hops landed before

entry and payment of duty, or without warrant for landing, shall be forfeited and burnt; the ship also shall be forfeited, and the person concerned in importing or landing shall forfeit 5*l.* a hundred weight, 7 Geo. II. cap. 19. By 9 Anne, cap. 12, there shall be paid a duty of 1*d.* for every pound of hops grown in Great Britain, and made fit for use, within six months after they are cured and bagged; and hop-grounds are required to be entered on pain of 40*s.* an acre. Places of curing and keeping are also to be entered on pain of 50*l.* which may be visited by an officer at any time without obstruction, under the penalty of 20*l.* All hops shall, within six weeks after gathering, be brought to such places to be cured and bagged, on pain of 5*s.* a pound. The re-bagging of foreign hops in British bagging for sale or exportation, incurs a forfeiture of 10*l.* a hundred weight; and defrauding the king of his duty by using twice or oftener the same bag, with the officer's mark upon it, is liable to a penalty of 40*l.* The removal of hops before they have been bagged and weighed, incurs a penalty of 50*l.* Concealment of hops subjects to the forfeiture of 20*l.* and the concealed hops; and any person who shall privately convey away any hops with intent to defraud the king and owner, shall forfeit 5*s.* a pound. And the duties are required to be paid within six months after curing, bagging, and weighing, on pain of double duty, two-thirds to the king, and one-third to the informer. No common brewer shall use any bitter ingredient instead of hops, on pain of 20*l.* Hops which have paid the duty may be exported to Ireland; but by 6 Geo. II. cap. 11, there shall be no drawback; and by 7 Geo. II. cap. 19. no foreign hops shall be landed in Ireland. Notice of bagging and weighing shall be sent in writing to the officer, on pain of 50*l.* 6 Geo. cap. 21. And by 14 Geo. III. cap. 68. the officer shall, on pain of 5*l.* weigh the bags or pockets, and mark on them the true weight or tare, the planter's name and place of abode, and the date of the year in which such hops were grown; and the altering or forging, or oblitering such mark, incurs a forfeiture of 10*l.* The owners of hops shall keep at their oasts, &c. just weights and scales, and permit the officer to use them, on pain of 20*l.* 6 Geo. cap. 21. And by 10 Geo. III. cap. 44. a penalty of 100*l.* is inflicted for false scales and weights. The owners are allowed to use casks instead of bags, under the same regulations, 6 Geo. II. cap. 21. If any person shall mix with hops any drug to alter the colour or scent, he shall forfeit 5*l.* a hundred weight. If any person shall unlawfully and malicious cut hop-binds growing on poles in any plantation he shall be guilty of felony without benefit of clergy. 6 Geo. II. cap. 37. By a late act, five per cent. is added to the duties on hops.

HUNDRED. In the time of king Alfred the kingdom was in gross, and then divided into counties and hundreds, and all persons came within one hundred or other.

By stat. 2 Ed. III. c. 12. it was enacted, that all hundreds and wapentakes granted by the king, shall be annexed to the king, and not severed. And by 14 Ed. III. c. 9. that all should be annexed, and the sheriff should have power to put in bailiffs, for which he will answer, and no more shall be granted for the future.

Hundreds are not answerable to persons who are robbed travelling on a Sunday. 29 Car. II. c. 7.

Hundreds are liable to penalty on exportation of wool. 7 and 8 W. III. c. 28.

Hundreds are liable to damages sustained by pulling down buildings. 1 Geo. I. c. 5.

Hundreds are liable for damages by killing cattle, cutting down trees, burning houses, &c. 9 Geo. I. c. 22, and 29 Geo. II. c. 36.

Hundreds are liable for damages incurred by destroying turnpikes or works on navigable rivers. 8 Geo. II. c. 20.

By cutting hop-binds, 10 Geo. II. c. 32. By destroying corn to prevent exportation, 11 Geo. II. c. 22. By wounding officers of the customs, 19 Geo. II. c. 34; or by destroying wood, &c. 29 Geo. II. c. 36.

All monies recovered against the hundred to be levied by a rate. 22 Geo. II. c. 46.

HUNGARY-WATER, a distilled water, so denominated from a queen of Hungary, for whose use it was first prepared.

Quincy gives the following directions for making it: Take of fresh gathered flowers of rosemary two pounds, rectified spirits of wine two quarts; put them together, and distil them immediately in balneo.

HURA, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. The amentum of the male is imbricated, the perianthium truncated: there is no corolla; the filaments are cylindrical, peltated on top, and surrounded with numerous or double antheræ. The female has neither calyx nor corolla; the style is funnel-shaped; the stigma cleft in twelve parts; the capsule is twelve-celled, with a single seed in each cell. There is but one species, viz. the crepitans, a native of the West Indies. It rises with a soft ligneous stem to the height of 24 feet, dividing into many branches. After the flower, the germen swells, and becomes a round compressed ligneous capsule, having 12 deep furrows, each being a distinct cell, containing one large round compressed seed. When the pods are ripe, they burst with violence, and throw out their seeds to a considerable distance. It is propagated by seeds raised on a hot-bed; and the plants must be constantly kept in a stove. The kernels are said to be purgative, and sometimes emetic.

HURDLES, in fortification, twigs of willows or osiers interwoven close together, sustained by long stakes, and usually laden with earth. See FORTIFICATION.

HURRICANE, a furious storm owing to a contrariety of winds. See WIND.

Hurricanes are frequent in the West Indies, where they make terrible ravages, by rooting up trees, destroying houses and shipping, and even whole plantations.

These dreadful convulsions of nature, Dr. Perkins, of Boston, supposes to be caused by some occasional obstruction in the usual and natural progress of the equatorial trade winds. The reason he assigns for this conjecture is, the more than usual calm which commonly precedes them. In the natural course of the trade winds, the air rises up in the line, and passes off towards the poles, and, in the more contracted degrees of the higher latitudes, takes the course of the west trade-winds, so that could their ascent be prevented through the whole circle of the zone, there would be no more west winds in those latitudes than in any other. Very

violent rains and cold, however, tend to check the ascent of air out of this circle, rather causing it to descend. Great clouds of vapour generate cold and wet, while rain beats down the air; and as these prevent the rising of the air out of the line, so they hinder its usual progress from the tropics on both sides; hence the calms which usually precede hurricanes. Calms, in these tropical regions, are caused by the ascent of the air into the higher part of the atmosphere, instead of its remaining near the line: the accumulation of air above then becomes heavier by the cold which it meets in those regions, and descends into the more rarefied region below. These heavy gales, therefore, will continue to descend till the upper regions are entirely exonerated.

HUSBAND AND WIFE, usually called baron and feme, are one person in law: that is, the very being or legal existence of the woman is suspended during the marriage, or at least is incorporated and consolidated into that of the husband, under whose wing, protection and cover she performs every thing. She is therefore called in our law French, a *feme covert*, that is, under the protection and influence of her husband, her baron or lord; and her condition during her marriage is called her coverture.

A man cannot grant lands to his wife during her coverture, nor any estate or interest to her, nor enter into covenent with her. But he may by his deed covenant with others for her use, as for her jointure, or the like; and he may give to her by devise or will, because the devise or will does not take effect till after his death. 1 Inst. 112.

All deeds executed by the wife, and acts done by her during her coverture, are void, except a fine, or the like matter of record, in which case she must be solely and secretly examined, that it may be known whether or no her act is voluntary. 1 Black. 444.

A wife is so much favoured in respect of that power and authority which her husband has over her, that she shall not suffer any punishment for committing a bare theft in company with, or by coercion of her husband. But if she commits a theft of her own voluntary act, or by the bare command of her husband, or is guilty of treason, murder, or robbery, in company with or by coercion of her husband, she is punishable as much as if she was sole; because of the odiousness and dangerous consequences of these crimes. 1 Haw. 2.

By marriage the husband has power over his wife's person; and the courts of law still permit an husband to restrain a wife of her liberty, in case of any gross misbehaviour. But if he threatens to kill her, &c. she may make him find surety of the peace, by suing a writ of supplicavit out of chancery, or by preferring articles of the peace against him in the court of king's bench, or she may apply to the spiritual court for a divorce propter sævitatem.

The husband by marriage obtains a freehold in right of his wife, if he takes a woman to wife that is seized of a freehold; and he may make a lease thereof for 21 years, or three lives, if it is made according to the statute. 32 Hen. VIII. c. 28.

The husband also gains a chattel real, as a term for years, to dispose of if he pleases by grant or lease in her life-time, or by surviving her: otherwise it remains with the wife. And upon execution for the husband's debt, the sheriff may sell the term during the life of the wife. 1 Inst. 351.

The husband also by the marriage has an absolute gift of all chattels personal in possession of the wife in her own right, whether he survives her or not. But if these chattels personal are choses in action, that is, things to be sued for by action, as debts by obligation, contract, or the like, the husband shall not have them, unless he and his wife recover them. 1 Inst. 351.

By custom in London, a wife may carry on a separate trade; and as such, is liable to the statutes of bankruptcy with respect to the goods in such separate trade, with which the husband cannot intermeddle. Burr. 1776.

If the wife is indebted before marriage, the husband is bound afterwards to pay the debt, living with the wife; for he has adopted her and her circumstances together. 1 Black. 143. But if the wife dies, the husband shall not be charged for the debt of his wife after her death, if the creditor of the wife does not get judgment during the coverture. 9 Co. 72.

The husband is bound to provide his wife necessaries; and if she contracts for them, he is obliged to pay for the same; but for any thing besides necessaries, he is not chargeable.

And also if a wife elopes, and lives with another man, the husband is not chargeable even for necessaries: at least if the person who furnishes them is sufficiently apprized of her elopement. 1 Black. 442.

A man having issue by his wife born alive, shall be tenant by the courtesy of all the lands in fee simple, or fee tail general, of which she shall die seized. Litt. 52.

And after her death he shall have all chattels real: as the term of the wife, or a lease for years of the wife, and all other chattels in possession; and also, all such as are of a mixed nature (partly in possession and partly in action), as rents in arrear, incurred before the marriage or after: but things merely in action, as of a bond or obligation to the wife, he can only claim them as administrator to his wife, if he survives her. Wood. b. 1. c. 6.

If the wife survives the husband, she shall have for her dower the third part of all his freehold lands: so she shall have her term for years again, if he has not altered the property during his life: so also she shall have again all other chattels real and mixed: and so things in action, as debts, shall remain to her, if they were not received during the marriage. Id.

But if she elopes from her husband, and goes away with her adulterer, she shall lose her dower, unless her husband had willingly, without coercion ecclesiastical, been reconciled to her, and permitted her to cohabit with him. 1 Inst. 32.

HUSBAND LAND, a term used in Scotland for a portion of land containing six acres of sock and scythe land, that is, of land that may be tilled with a plough and mown with a scythe.

HUSBANDRY, in the general sense of the word, comprehends the whole practice of agriculture; in which we have to consider the nature of the soils we meet with, on and near the surface of the earth. The methods of correcting those which are unfavourable to the production of useful vegetables; the improvement of such as are deteriorated by over-cropping; such implements as

are fittest for facilitating the operations of agriculture; the means and powers best adapted for such purposes; the cattle and live stock most profitable to man, whether for labour or more immediate use as food; the grass, grain, roots, and pulse, most beneficial to him; and the minor subjects connected with this important science.

The culture of the earth is coeval with man; his beneficent Creator placed him in a well-stored garden, enjoining him "to dress and to keep it;" and after a fatal lapse of obedience, he was driven from his paradisical situation, a new injunction was laid on him, "to till" the ground, "that thorns and thistles" may not choak the better production of it. Adam, "by the sweat of his brow," so cultivated the soil, that it produced a sufficiency for himself and family: his sons he instructed in the art, and they communicated the same to their descendants: and thus the knowledge and practice of agriculture were promulgated through the early ages of mankind.

When the deluge had swept away from the face of the earth every vestige of human art, the ark excepted, Noah and his descendants found themselves under the necessity of reviving the practice of husbandry, as one of the surest means of procuring the necessaries and comforts of life. The methods pursued by the early generations are unknown to us, as are most of the implements which they employed; perhaps the mattock and coulter were their principal tools.

It seems probable that the inhabitants of the ages which immediately succeeded the flood, knew not the proper methods of restoring fertility to an exhausted soil; for we find them frequently changing their place of residence, as their flocks and herds required fresh pasturage, or their tillage land became unproductive. When the descendants of Abraham settled themselves in Palestine, agriculture began to raise itself into importance, and was considered not only as an useful but honourable employment. The Chaldeans, who inhabited the country where agriculture had its birth, cultivated the land with great assiduity, and seemed to have found out the means of restoring fertility to an exhausted soil, having plentiful harvests in succession, so that they were not obliged, as their predecessors had been, to be frequently changing their situation, in order to obtain a sufficiency for themselves and their numerous flocks and herds. The Phœnicians were also remarkable for their skill in agriculture. The Athenians taught the rest of the Greeks the use of corn, and how to cultivate the land that it might produce so wholesome a food. As the arts of agriculture encreased, and the blessings they afforded became more generally known, these savage Greeks forsook their acorns, and the wild roots of the field, and applied themselves assiduously to the cultivation of the earth; their kings encouraging such laudable pursuit. The old Romans esteemed agriculture so honourable an employment, that one of the highest praises which could be given to a man, was that of saying he had well cultivated his spot of ground. The most illustrious senators, in the intervals of public concerns, applied themselves to this profession.

The art of husbandry was at a low ebb until the fourteenth century; at which time it began to be practised in the midland and south-western parts of England; yet it seems not to have been cultivated as a science, until the latter end of the sixteenth century; when Fitzherbert, a judge of the common pleas, studied the nature of soils and the laws of vegetation with philosophical attention; and in 1534 published his first work entitled, "The book of Husbandry." Beyond which, small advances only were made in the theory until the time of the commonwealth; when sir Hugh Platt, one of the completest husbandmen of the age, discovered and brought into use a multitude of manures, little thought of by others, for meliorating and fertilizing exhausted soils. At the time of the Restoration, agriculture appears to have suffered considerable neglect, until Evelyn and Tull, by their literary labours, mightily promoted the study. Since their days, many valuable improvements have been made in the practice, and many are the writers who have rendered essential services, by enlightening the minds of their countrymen, and exciting them to emulation. In our own days, with pleasure we behold many respectable agricultural societies established in different parts of the kingdom, greatly contributing to the advancement of the practice as well as theory of agriculture; among which we must particularly notice that of high national concernment, instituted a few years since, under the title of the "Board of Agriculture."

About the year 1790, sir John Sinclair, a gentleman of genuine patriotic philanthropy, conceived an idea that such a board, properly constituted, would be of vast importance to the agricultural interests of the kingdom. Having, with much attention to the subject, matured his plan, and communicated the same to some of his parliamentary friends, in May 1793, "An address from the honourable house of commons was presented to his majesty, entreating that his majesty would be graciously pleased to take into his royal consideration the advantages which might be derived by the public from the establishment of a board of agriculture and internal improvement."

After surmounting the difficulties naturally attending the formation of such an institution, the charter for the same was drawn up, and sanctioned by the authority of the great seal, in August of the same year, and the founder elected president. To this society we are indebted for 80 volumes of the most useful agricultural knowledge, which could be procured from literary men, resident in, or intimately acquainted with the respective counties, under the title of a "General View of the Agriculture thereof, with observations on the means of Internal Improvement." The grand outlines of the plan of these views are, the geographical state of each county, the state of property, farm buildings, mode of occupation, implements, fences, arable land, grass, orchards, plantations, draining and other improvements, live-stock, rural economy, means of improvement, &c.

A work comprising so many important objects in the science of agriculture, cannot fail of producing national benefits, greater perhaps than have been derived from any other political institution of modern times.

Besides the county reports of agricultural views, the board have published sundry volumes of communications on various topics of husbandry, which have been transmitted to them by writers fully conversant with the sub-

jects of their respective communications. By pursuing such plan for a few years, and publishing to the world such communications, under some systematic arrangement, we may expect that agriculture will become the best understood, and the most accessible of any art in the whole circle of human acquirement.

Soils. A land considered as the basis of vegetation is called soil. The particles of the various solid, as well as less compact bodies, that are met with in nature, and which have been rubbed down and reduced by the successive operations of the atmosphere, and the agency of other natural causes, being mixed and blended together in different ways and proportions, constitute the earthy compounds, which, from their being capable of absorbing, and in some measure retaining, moisture, as well as giving stability, afford the means of support to various products of the vegetable kind, and form the bases of soils in general; while the materials proceeding from the decomposition and decay of numerous organized animal and vegetable substances, uniting with such compounds, compose the superficial layers of rich mould, from which plants chiefly draw or derive their nourishment and support.

Soils being formed in this manner, it is evident they must vary much, both in the qualities and proportions of the ingredients of which they are composed. In one situation or district one sort of material is abundant, and consequently enters largely into the soil; in others it is deficient, while those of other kinds are plentiful, and constitute the principal parts of the soils where they are found. Some situations too abound much more with animal and vegetable matters than others, which produce great diversity in regard to the soils. The harder and more firm substances of nature, being, on account of their structure, reduced more slowly, and with greater difficulty, into the state of earth, generally enter in much smaller proportions into the composition of soils, than those which are of a soft and pliable disposition, and which approach nearer to the quality of earth. Thus argillaceous, loamy, and vegetable matters are found to predominate very much in soils in their primitive state, and, according to their particular qualities and proportions, to constitute very material differences in their properties. Calcareous and siliceous earthy matters are distributed over some districts in great abundance, while in others they enter into the composition of the soils in much smaller proportions, and thus contribute to vary their textures and qualities.

One of the means of deciding in respect to soils, which, in many cases, when properly limited and exercised, by a person of sound judgment and duly experienced, is certainly not a bad one, though in some respects also defective, is that of determining from the nature of the plants that are naturally produced, and the degrees of their growth and luxuriance. Thus, where plants that are only accustomed to grow in good or peculiar sorts of soil, are met with in their natural and flourishing states in other places, the soils may be concluded to be of this or that kind, according to the circumstances in which they are found. The growth of certain sorts of timber trees and hedges, may also in various instances serve to direct the judgment, and likewise the appearances or colours of the mould in particular instances; the smell and the touch will also help to inform us of the quality of a soil: the best emits a fresh pleasant scent, when fresh dug up; and if due proportions of clay and sand are intimately blended, it will not much stick to the fingers in handling. But, however, that our readers may be informed of some of the leading principles which chemistry employs, in analising soils, we give him the following, which may be depended on.

1. To ascertain the quantity of water in any soil, take a pound of the soil, spread it very thin before the fire, or in the sun-shine in a warm day, let it lie till it is thoroughly dry; the evaporation of the water will be known by the weight lost.

2. To know if there are any metallic or earthy salts, take a pound of soil, pour upon it a pound of boiling distilled water, stir them thoroughly together, and let them stand for ten minutes, filter off the water through filtering paper, pour into what comes through a solution of the fixt vegetable alkali; if there is any earthy or metallic salt, a precipitation will take place.

3. To know if the salt contained has calcareous earths for one of its elements, take the filtrated solution, pour into it half an ounce of caustic volatile alkali, or continue to drop in this alkali till no further precipitation takes place; afterwards filtrate it, and pour to what filtrates through a little solution of fixt vegetable alkali; if there is any further precipitation, it shows that there is an earthy salt consisting of calcareous earth for one of its elements; if a precipitation took place upon the application of the caustic volatile alkali, it shows that there certainly are earthy and metallic salts.

4. To know if the salt contained is metallic or aluminous, add to the filtrated solution an infusion of galls; if there is any metallic or aluminous salt, a precipitation will take place; if iron, a purplish black; if copper, or allum, a grey: copper may also be distinguished from iron by falling in a blue precipitate upon the application of an alkali, while iron forms a greenish, and allum a white one.

5. To know if magnesia is an element of the salts found, take the filtrated solution, apply to it a solution of galls; if no precipitation takes place, apply caustic volatile alkali, which will precipitate the magnesia if it is an element of the salt contained.

6. To know if a neutral salt is contained, evaporate the filtrated solution with a boiling heat, till the whole water is nearly gone off, and let it stand to cool: if there is any neutral salt, it will crystallize.

7. To know if there is any mucilage, and what quantity, take 30 or 40 lbs. of the soil, boil it in 10 gallons of water for an hour, let the earth subside, pour off the clean solution, afterwards add four or five gallons of water to the earth, stir them thoroughly, let them stand to subside, pour off the water clear, mix it with the former, and evaporate the whole to dryness, putting it into a water bath towards the end of the evaporation: what remains is the mucilage, making allowance for that part of the decoction which was not washed out from the earth, and deducting the saline substances, which will crystalize if there is a considerable quantity, but will be destroyed in the operation, if in small proportion, as they generally are.

8. To know if there is any calcareous earth in the soil,

and what quantity, take $2\frac{1}{4}$ oz. of the dry soil, apply to it $\frac{1}{2}$ oz. of muriatic acid, and 4 oz. of water in a glass vessel sufficiently large; let them stand together till no more effervescence takes place; and if it was very considerable, pour in $\frac{1}{2}$ oz. more of the acid, let this stand also till the effervescence ceases, if any arises upon pouring it in, continue to add more acid in the same manner, until what was poured in last produces little effervescence, which is often at the first, and generally at the second or third half ounce. After the effervescence has ceased, put the whole in a filter, let the solution filtrate through; pour half a pint of water upon what remains in the filter, let that filtrate also in the same vessel; add to the solution thus filtrated $1\frac{1}{2}$ oz. of caustic volatile alkali for every ounce of acid used; if any precipitation takes place there is magnesia, earth of allum, or the calx of a metal (generally iron or copper) contained in the soil; after adding the volatile alkali, the whole is to be thrown into a filter again; after the filtration has taken place, pour into the liquor a solution of mild fixt vegetable alkali in water; if there is any calcareous earth in the soil, a precipitation will take place; continue to add the solution of the alkali till no fresh precipitation ensues, throw the whole into a filter, let the liquor filtrate off, pour on by degrees a pint of water, let that filtrate off also, dry what remains in the filter, it is the calcareous earth.

9. To know the proportion of sand and clay, take what remains in the filter after the first solution in the foregoing operation, and by the elutriation separate the sand from the clay, dry and weigh them; if there is any pyrites it will appear in the sand.

In the above processes the principal things to be attended to are, whether there are any metallic or aluminous salts, as these are absolute poisons, and therefore are to be decomposed by quick lime; whether there is such a proportion of neutral or earthy as to be hurtful, in which case the solution in process 2. will taste salt, a soil containing them in so large a proportion will hardly ever admit of culture for grain: whether there is calcareous earth, and in what proportion, as that ascertains the propriety of applying any manure containing it, and the quantity of that manure: what the proportion of sand and clay is which ascertains the propriety of adding clay or sand: whether there are pyrites, as that shows why, and when a soil will be long in being brought into cultivation; pyrites are best destroyed by fallowing, and afterwards applying lime.

The soils of this country have been described under numerous heads, and distinguished by a variety of vague local terms. They seem, however, to be capable of being considered and characterised, as far at least as is necessary for practical purposes, under the distinctions of

Clayey,	Gravelly,
Loamy,	Peaty or Mossy, and
Calcareous,	Vegetable Earthy soils.
Sandy,	

Each of these divisions must of course comprehend several varieties, according to the nature and preponderancy of the different sorts of materials of which they are constituted or composed. By different combinations of these substances all the intermediate kinds of soils are formed; and upon a proper mixture of them, in certain proportions, depends the success of the farmer's industry. Sand, clay, and water, are the grand component parts, whatever colour or texture the soil may happen to have.

Clayey or argillaceous soils. Soils of this kind differ very materially, according to the nature and quantity of the clay that enters into their compositions, and the adulteration which has been produced in it by the intermixture of different earthy matters, as well as various mineral, vegetable, and animal substances. For clays are, in general, far from being pure in the states in which they are found in the earth. They are in many instances united with large proportions of siliceous or sandy matter. On these accounts it is that the clayey soils of some districts are so abundantly fruitful and productive, while those of others are insuperably sterile and refractory.

These facts not only show that there is a prodigious variety in respect to the qualities of these substances, but that they must afford equal variety to the soils into which they enter, and therefore require to be more closely examined, and more nicely ascertained than they appear yet to have been, before all the varieties of soil usually classed under the denomination of clayey can be well ascertained and understood.

But these substances do not differ only in their properties and qualities, but likewise in their colours, and the closeness with which their particles are united. They are found in their natural states of various colours, such as red, white, blue, and yellow, and of different degrees of density, so as, in some instances, readily to admit of being united with the different materials that are applied, in order to meliorate their conditions; in others they can scarcely be made to join with them by any means in the power of the agriculturalist. In soils of the first kind, the quantity of siliceous or sandy matter, in general, bears a much larger proportion to that of the argillaceous or clayey, than in those of the latter, and in many cases too the mixture of other substances is proportionally larger. The nature of the clayey stratum, in respect to its thickness or thinness, as well as its contiguity, or remoteness from springs of water underneath it, is too commonly overlooked in considering these sorts of soils; but all these circumstances demand particular attention, and ought to have considerable influence in directing the means of cultivating and improving clayey soils.

It is obvious, from what has been already advanced, that, notwithstanding the differences that take place from the accidental mixture of different materials, in different degrees and proportions, all the descriptions of this sort of soils must possess more or less of the heavy and adhesive stiff qualities; and that according as these are more or less predominant, due respect being at the same time had to the various other circumstances that have been stated, the business of cultivation and improvement must be varied and applied.

Loamy soils. Loam denotes any soil which is moderately cohesive, that is, less so than clay, and more so than loose chalk. Soils, therefore, of this description admit of considerable variety. The substances that are most commonly found to contribute to the formation of loamy soils, are clay, sand, gravel, and chalk: and as either ingredient predominates, so is the soil denominated, as clayey loam, sandy loam, &c. Clayey loam is moderately cohesive, in which the argillaceous ingredient predominates; so that its coherence is greater than that

of any other loam, but less than that of pure clay. Besides the argil silex enters largely into the composition. Sometimes an oxide or calx of iron in small proportion is found blended with the clay and sand. In proportion as the argillaceous or clayey principle diminishes, they recede from the nature of the clayey soils; consequently the nearer the quantity of that substance approaches to that of the others, the stronger and more heavy will the loamy soil be. The differences in the lightness and friability of the soils of this class, in a great measure, depend on the relative proportions of the other ingredients. Where the calcareous ingredient greatly exceeds those of the sandy or gravelly kinds, they are neither so light or so pulverizable as where they are nearly equal, or where the sandy or gravelly matters considerably predominate over it.

In situations where this sort of soil has been but little disturbed, and consequently little changed by the artificial additions of either animal or vegetable substances, and those which it naturally contained not having advanced to the stage of perfect solution and decay, it is generally found of a light brown or hazel colour; but where much culture has been employed for a length of time, and large applications of animal and vegetable matters frequently made, the natural and artificial materials of these kinds having proceeded more nearly to the state of perfect resolution and destruction, it has an appearance that approaches to black. From these various circumstances the properties of the soils are likewise considerably altered and affected, as well as their colours changed.

From the soils of the loamy class being more friable and brittle, as well as more dry, than most of the clayey ones, they are capable of being tilled with much greater ease and facility, as well as much less strength of team, and at almost every season of the year. And, on account of their property of receiving and transmitting moisture more freely, they are less apt to be indurated by too much dry, or chilled by too much wet weather. Besides, they are more influenced on exposure to the agency of the atmosphere and other external causes, and thereby more adapted for the promotion and support of vegetation. And as they are found in most cases to be less disposed to the production of weeds, particularly those of the more injurious kinds, they can of course be kept clean with less labour, and without the expensive system of management which is requisite on many other kinds of soil.

Chalky or calcareous soils. Soils of the calcareous kind, which are composed of clay, sand, and chalk, occupy very extensive tracts of land in different parts of the world, and are marked with considerable diversity, as proceeding from the nature, properties, and proportions of the calcareous matter as it exists in them; the substances that are mixed and combined with it; the depth and qualities of the earthy stratum which is placed upon it, and the disposition of the sub-soil or basis on wich this is formed and deposited.

Calcareous matter is contained in many different stony substances, besides that of chalk, as marble, lime-stone, coral, and shells of different kinds; and in states of union with other materials, such as sand, the different simple earthy bodies, in different proportions, and in some instances with iron and magnesia. Its capability or powers of imbibing and retaining moisture is considerable, though not so great as that of clay. It burns to lime by proper degrees of heat, and absorbs carbonic acid gas, or fixed air in different proportions from the atmosphere, and returns again to the state of chalk or mild calcareous matter. It is found of very different degrees of hardness and friability, as well as of different states of fineness or pulverization, in different soils of the class to which it belongs. It varies also greatly in its effects in respect to vegetation; from the different matters that may happen to be combined with it in its primitive or original state. It has long been known to the practical agriculturist, that some sorts of lime may be employed in large proportions, while others cannot be used, except in very small quantities, without doing very considerable injury to the soil with which they are incorporated.

Calcareous matter, whether it is in the state of carbonat, or in the more active one of causticity, as quicklime, seems ultimately to promote the resolution and destruction of vegetable and animal substances; in the latter state, however, it acts with much greater violence on these materials, destroying their organization, and dissipating their principles more quickly, as well as robbing them more completely of the carbonic acid gas, or fixed air, which is so essential, while in the former it operates with great mildness, and only aids the resolution of those substances by gently promoting the process of putrefaction.

The proportions of clayey, loamy, and gravelly ingredients, which are conjoined with the calcareous matters of these soils, are various in different districts; where the argillaceous and loamy materials are comparitively in large quantities, soils of the heavier chalky kinds are formed, and where the sandy or gravelly are predominant, we have the lighter ones. There are also material differences proceeding from the earthy matter with which the calcareous ingredient is mixed in the state of soil. Where the quantity of this is small, and not reduced into any very perfect state of mould, the soil, as it is evident, must be poor and thin; but where the depth of this superficial stratum is considerable, and the animal, vegetable, and other substances of which it is composed, is advanced to a more complete stage of decomposition and decay, the soils are more rich and heavy. Some variety is likewise caused by the state of the under-stratum or sub-soil. If it is compact, and much intermixed with silecious or flinty matter, or have a mortary hardness, it is less favourable than where it is of a more open, brittle, or powdery texture.

Whatever appearances of lightness there may be in chalky soils, they require considerable strength in the team, where the staple or earthy stratum of the lands will admit of their being wrought to a tolerable depth; but where there is a thinner surface of earthy materials, less force of draught will be requisite. In the latter cases, the soil is, however, far more precarious and uncertain, as well as much less productive in respect to the crops that are cultivated upon it, than in the former. As chalky soils are not so liable to be injured by water as others, the business of tillage is much less impeded from that cause; but a dry season sometimes renders them so hard as to be totally incapable of being broken up, until they

have been moistened by the falling of a considerable quantity of rain.

Sandy or siliceous soils. Sands seem to have been gradually formed by the attrition and rubbing down of the various solid substances that are found in nature, especially such as are of the siliceous, calcareous, and stony kinds, and are of different degrees of fineness as they approach the size of gravel. They are also met with of various colours and appearances in different regions or tracts of country, such as white, dusky brown, yellow, and red. These differences, as well as those which respect their weight, tenacity, and other properties, depend on the nature and proportions in which many other materials enter into combination with them.

Where the proportions of clayey, loamy, or other earthy substances with which they are mixed, approach nearly to that of the sand, the heavier sorts of sandy soils are formed; but where these enter only in very small quantities, we have the light sandy soils; and where they are hardly met with at all, the soil is a loose blowing sand, most commonly of a white or brownish appearance. The portions of vegetable matters that are intermixed with different soils of the sandy kind are not less various than those of the clayey and loamy, from which considerable differences of quality are produced. These differences in their textures and compositions also introduce others which respect their powers of admitting and retaining heat and moisture. The openness and want of adherence in such soils, while they allow of the admission of heat and water more readily, permit them to be carried off with greater ease and expedition, they are therefore less permanently benefitted by their influence than the closer and more adhesive soils.

The light, open, and porous texture of sandy soils renders them much more easily cultivated and kept in order than those of the strong and close kinds; consequently the farms where they prevail are generally large; and when properly prepared, they are better adapted for the growth of many sorts of crops, such as those of the bulbous and tap rooted sorts. They have also another advantage, which is that of pushing forward the crops with more expedition. Whatever inconveniences attend them are mostly such as proceed from the want of a sufficient degree of cohesion among their constituent particles and solidity of texture. On these accounts they often counteract the best and most judicious management. The roots of the crops are liable to become naked and exposed from storms and various other causes; and if grain, to fall down and be lodged so early in the season as to render them of little value.

Gravelly soils. In the state of gravels which contribute to the formation of this class of soils, there is a variation of size in the pieces or particles of which they are composed, from that of a very small pea to the largest cockle. Where they become of still larger dimensions they are termed stones or rocks, according as they are in small portions or large masses; and the soils are then said to be stony or rocky, as the circumstances of the different cases may happen to be.

The beds of gravel, whether they are of the larger or smaller kinds, are mostly either of the siliceous or flinty kind, or of the calcareous or chalky; but the stones and rocks are of very different kinds. With these dissimilar substances, some others in different states of reduction and pulverization are blended and united in various proportions, so as to constitute gravelly soils that differ considerably in their textures and other properties. The chief of these are loams, and the mould or earthy matter formed by the destruction and decay of numerous animal and vegetable substances.

The gravelly mixture is sometimes also found to approach nearly to the surface, while at others it recedes considerably from it. In some instances springs rise immediately underneath; in others they are at a great depth, The bottom, or sub-soil, is likewise various; in some cases it is stony and rocky, in others it is clayey, or a rocky gravel, and sometimes sand, &c.

The open porous nature of gravelly soils disposes them to admit moisture very readily, as well as to part with it with equal facility; from the latter of which circumstances they are subject to burn, as it is termed, in dry seasons, which is not the case in the heavier or more retentive sort of soils.

Gravelly soils, from the lightness of their texture, and their not affording great resistance, except where the stones are large, or there are rocks, are not expensive or difficult in the means of cultivation. All the necessary business of this sort is capable of being carried forward with much ease and expedition, and the lands are in general soon brought into the proper states for the reception of crops.

Peaty or mossy soils. These soils consist chiefly of the roots of decayed vegetables, mixed with earth, mostly argillaceous, and sand, and a coaly substance derived also from decayed vegetables. They differ, like all the other kinds of soils, according to the nature of the ingredients of which they are constituted or composed, and the proportions in which these are found to prevail in them. Where the vegetable or peaty material predominates but little over the other substances with which it is mixed and incorporated, the lighter sorts of peaty, moory, or heathy soils, are formed; but where the other matters bear only a slight proportion to it, the deep and heavy, peaty or mossy, soils present themselves. In different districts the peaty matter is found of different depths, and of various degrees of density or closeness of texture, probably proceeding from some original differences in the vegetable substances from which it was formed, or the greater advances which it has made to the state of perfect decomposition or decay. The sub-soil in most of the deep mossy districts is of the clayey kind, more or less stiff and heavy, over which the peaty or mossy material is deposited, generally in a sort of stratified order; the first layer of which being commonly not more than ten or twelve inches in thickness, exhibits the appearance of a rich brown earth, in all probability from the incorporation of the loamy or clayey matters, with the peat or vegetable earth, laying immediately upon them, and constituting originally, perhaps, the surface of the ground. The layer that succeeds to this is mostly of a dark colour, and considerable thickness, apparently formed of a great variety of vegetable materials in the more perfect stages of resolution and decay, united together by time and other circumstances with more or less compactness and solidity. The uppermost stratum, or that which is placed upon this dense, peaty matter, is,

in general, of very pale colour, and very light spongy texture, arising possibly from the grasses, leaves, and other vegetable substances, of which it is formed, not having attained that state of decay which constitutes the darker sorts of peaty earth.

But in the more superficial peaty soils, little or nothing of this stratified appearance is met with. A coat of peaty earth, differing greatly in thickness according to the peculiarity of the situations, and other circumstances, is formed by a great length of time from the destruction and decay of successive crops of grasses, leaves and substances of the heathy or other kinds, and deposited upon, and intermixed with, the various harder materials of the soils which happened to be underneath them. By these means much variety is produced in the soils. Where the under-strata of earthy matter are tolerably good, and the crops of vegetables large and luxuriant, the better sorts of light peaty soils seem to be predominant; but where the quality of the under strata are indifferent, and the vegetable products scanty, as well as feeble in their growth, and principally of the heathy tribe. the poor peaty and heathy, or moory soils, are met with.

All peaty soils seem to be thus gradually formed by the deposition of vegetable matter, supplied by the dissolution and decay of aquatic and other plants that grow in low moist situations, as well as substances of other kinds brought down by water, from the high grounds in their neighbourhood. in the states of solution and diffusion, and gradually deposited from it on its becoming in a state of stagnation, by means of obstruction and stoppages proceeding from different causes.

From the nature of the composition of these soils, it is obvious that they must be very retentive of water, especally where they are of any great depth. Hence they seldom or ever become free from the excessive quantities of moisture, with which they are loaded in the rainy seasons.

Vegetable earth or soil. This kind of earthy material constitutes the superficial bed or stratum, in which plants for the most part vegetate in every sort of soil, and differs very much in different places, from the variations that take place in its depth, and the greater or less progress that has been made in the several substances of which it is composed, to the stage of perfect decomposition or decay. Some variety may likewise be caused by its being more intimately or more loosely mixed and blended with the other bodies that are found in soils. It seems probable too, that the earthy matter which is formed from the destruction of some sorts of vegetable substances may be better suited for the purposes of vegetation than that which proceeds from others.

Vegetables. from their containing a considerable portion of mucilaginous matter in a state of mixture with their other substances, become, in some measure, capable of solution in water, though the external surfaces of living plants, on account of the resinous and animalized materials that enter into their composition, are protected from its operation. From the former circumstance, and that of earthy matters being contained in them, which had been taken up in the state of solution with their fresh juices while growing, it is evident that large quantities of vegetable mould must be continually formed and deposited on lands by the natural decay of such substances.

But the formation of vegetable mould or earth is farther effected by means of the putrefaction or dissolution of such vegetables as are cut down, or otherwise destroyed, on the surface of the ground, and the application of various kinds of dung and composts. Where there have been in great abundance for a long time, there is mostly a deep rich surface soil of this earth; but where few vegetable products, and those of the less luxuriant kind, have been left to undergo the above process, or little assistence given by means of manures, the crust of surface mould is generally thin and poor. The resolution of vegetable matters is greatly promoted by a proper degree of moisture and heat, as well as a suitable state of the air.

From the preceding account of soils, we may perceive that those are the best which contain the greatest store of those principles which constitute the pabula of vegetation. Such are calcareous soils, in which carbon must exist in large quantities, from the natural attraction of lime for carbon, and where there will be a constant supply by means of this attraction. Soils formed from the decomposition of animal and vegetable matters, are in their natures eminently favourable to vegetation; for they contain hydrogen and carbon combined, together with the remains of animals and vegetables, as yet only tending to decomposition, with various salts resulting from the decomposition of animal bodies, water, earth, and gaseous principles.

Improvement of soils. From various causes, we perceive that some sorts of soil are less adapted to a vigorous production of vegetables than others. To improve the less fertile is a main branch of husbandry. According to circumstances, various methods must be employed; such as commixing one kind with another; draining such as are too retentive of moisture; irrigating such as are by nature too dry; and refreshing those with manures whose fertility has been exhausted.

Of commixing various soils. Chemical analysis has shown that substances of the calcareous kinds are the most beneficial in bettering the condition of clayey soils. Where the deficiency is in the want of calcareous matter, lime-stone, gravel, and calcareous marls are the most proper. If, however, these substances cannot be conveniently procured, a mixture of the coarser sands with lime and dung may be employed; or even coal ashes, sea sand, or chalk in the state of coarse powder may be advantageously used.

Loamy soils stand not in need of so much commixture with other substances as clayey soils; the soil of ponds, ditches, or even a small proportion of clayey soil may however be applied to advantage, and especially dung.

Chalky or calcareous soils of the heavier sorts may be benefited by the application of sandy loams; the lighter sort. by clay. dung, and argillaceous marl.

Sandy soils may be improved by applying calcareous marl, argillaceous and loamy ingredients, and by the use of the fold.

Gravelly soils of the calcareous kind may be improved by clay, clayey loam. or chalk.

Peaty soils. after being properly drained of their superfluous moisture, may be improved by the application of gravel, common sand, coarse earth, chalk, calcareous marl, dung, or sea sand. See Draining.

Irrigation or watering land. The systematic manner of watering meadow land, as now practised, is of modern invention, but of material importance to that farmer who possesses land of proper quality, and commands a stream of water suitable to the purpose; as he will be enabled to procure an earlier and fuller crop of grass than he could by other means.

Water, independent of any substances it may hold in suspension, is of universal utility in vegetation; being composed of two chemical elements (hydrogen and oxygen) which are highly favourable to vegetation, and directly and powerfully nutritive to plants. It enters, even undecomposed, as an aliment into the organization of vegetables. It is the only vehicle by which nourishment can be conveyed from solid bodies to plants. And whatever gaseous food the roots of vegetables receive, it is presented to them by the intermediation of water. Although thus beneficial when administered in season and due proportion, yet an excessive affusion of water tends to the destruction of many of the better grasses, and to the nourishment of rushes, mosses, sedge, and other aquatic weeds. A gentle affusion of this fluid, dispersing itself in all directions, never stagnant, never running with great impetuosity of current, more copiously applied in the light and under the heat of the sun than in the dark, operates with the best efficacy, as a promoter of vegetation.

The idea of watering meadows, so far as it relates to bringing the water upon the land, was undoubtedly taken from nature. It must have been always observed that winter floods produced fertility, provided the water did not remain too long on the land. The idea of taking the water off the land at will, and bringing it on again at will, is the effect of art; and the knowledge of the proper seasons to do this, is the effect of observation.

Suitable soils for water meadows are such as are of a sandy or gravelly nature, especially in the nearest subsoil. A bed of flints, or loose gravel, is the most desirable. It is also observable, that whatever may be the most abundant grasses in a meadow before irrigation, those kinds will always predominate which best agree with the soil and the water, provided the supply of water is regular and constant every winter.

There are two distinct methods of watering land, according as a less or greater quantity of water can be commanded. If the water is taken from a streamlet, near to the spring head, and the quantity small, only a small portion of land can be irrigated at a time, the water carriages and floating sluices are laid out, and cut in a form which (provincially) is by some called catch-work, by others frame-work. But where a river or large stream can be commanded, the work assumes another appearance, and being of greater power than the foregoing, is called flowing-work.

It is necessary, before entering upon works of this kind, to consider whether the stream of water to be employed will admit of a temporary weir or dam to be made across it, so as to keep the water up to a proper level for covering the land, without flooding or injuring other adjoining grounds; or if the water is in its natural state sufficiently high without a weir or dam, or to be made so by taking it from the stream higher up more towards its source, and by the conductor keeping it up nearly to its level till it comes upon the meadow or other ground. Further, if the water can be drawn off the meadow or other ground as rapidly as it is brought on.

This is to be done by the use of a spirit level, beginning from the highest part of the land that the stream can be commanded from, where the grounds on the different sides are the property of the same person, and weirs, or other works, as has been just observed, can be carried across the streams for the purpose of forcing the water, either wholly or in a partial manner, into a different course. After it has been raised as high as possible in this way, the level is to be formed from the surface of the water, carrying it on what is termed the dead level, allowing some small degree of depression for the flow of the current.

After this has been done, the land on the different sides of the stream, below the lines set out by the level should be minutely examined and inspected, as the whole may be irrigated if the command of water is sufficient. The extent that can be properly performed must however depend much on the degree of fall or descent from the entrance of the water and its out-fall, as well as on the declination of the more elevated parts of the ground.

The next circumstance of importance is that of deciding where to commence the business. This must depend on various points, which can only be settled by the judgment of the operator. If there is a full supply of water, the whole should be covered; but in the contrary case, the expense of cutting the mains or carriers on such levels in a sufficient manner should be considered; and where one side of the stream is better adapted to the purpose than the other, that on such side should be the first executed. And if the land most adapted to the purpose of watering is at much distance from the place whence the water is first taken, and there is not a supply for the whole of the land below the line of level on one of the sides, the expense of forming the carrier should be put in comparison with the greater advantage of irrigating the most suitable grounds, in preference to others that are nearer, without possessing equal advantages. It mostly happens that the beneficial consequences of irrigating at command are such as to overbalance that of forming the mains or carriers. Besides, though the supply of water may be insufficient in such seasons as are very dry, as it may be abundant in the winter time, the simply covering the land at that period may be more than adequate to the expense of the business, which is a circumstance that may render it more beneficial to lengthen the carriers, than by having them shorter to be confined to the watering of such lands as are less proper for the purpose. It is probable also, that in particular cases the winter irrigation may extend through the whole of the level that has been set out.

Where it can be done, it is best to begin with such parts as are contiguous to, or approach the nearest the mains or carriers; and after having passed the water over them, to mark the lowest places, where it can be carried off to the best advantage; and from such parts it should then be seen to which other lands the water can be conducted with the greatest facility and benefit. Where the natural shelving of the ground is considerable, less care is necessary; but where this is not much, it may often be requisite to convey the water in a slanting direction for a

considerable way, before lands sufficiently low for being covered by it are met with; as in this sort of business it is invariably necessary, in order to prevent the waste of water, to proceed with that which is first made use of to its final outlet into the river before the works on other divisions are commenced.

When the piece of ground to be floated is so much upon the level that the descent cannot easily be determined by the eye, it will be necessary to take an accurate level, and compare the highest part with the stream intended to be used, by which the degree of fall from the surface of the water to the highest point of the land will be ascertained; and in order to convey the water to this point, should it be distant from the stream, the sides of the ditch or canal should be sufficiently raised for the purpose not to keep the water in a dead level, but with such degree of descent as the two points will admit of. In the operation of cutting this canal or main feeder, it will be easy to preserve the proper degree of fall, having previously ascertained the length, for instance, in cutting 50 yards with a fall of five inches, it will be obvious that in every ten yards a descent of one inch should take place, this is necessary to keep the water in a constant lively motion. In some cases it may be necessary to have two main feeders, in order to affect a more equal distribution of the water; the depth and width of which feeders must be regulated by the supply requisite for the smaller gutters. Near to the mouth of the canal or feeder it will be proper to have a flood-hatch or clow, by which the water may be admitted or excluded at pleasure.

In forming the floating gutters, it is perhaps the best method to cut them at right angles, or nearly so, to the feeders; however, where the surface is uneven, in order to preserve a regular descent, a different direction must be given to them, the distance from each other being about ten yards, and the gutters becoming, as has been observed, gradually narrower as they recede from the main canal or feeder. The object in view being to throw the water as evenly over the surface as possible, these gutters should be so constructed that the water which has been introduced may overflow their little banks rather than run rapidly along the bed. Obstructions may sometimes occur, such as low parts, or deep ditches, over which a pipe or spout may easily be made to continue the progress of the water; and such as proceed from ridges, roads, or small eminences, by trunks or other contrivances made to convey the water underneath them.

It has been observed, that there are two distinct methods of watering lands, catchwork and flowing. The methods of making such works may be thus described. From the spring at A, Plate LXIX. Husbandry, fig. 13, take the level towards C; to include as much of the meadow BCDE as possible. Cut the trench or main drain AC of a width and depth sufficient to take all the water issuing from the spring, and convey it to the proposed meadow. Cut also the carriage gutter of a sufficient depth to take off the waste water which may fall into it; and also float sluices, &c. laid out by a level, placing sods taken from the sluices on the lower side. Was the meadow small, of a smooth surface, and regular declivity, the water might be let out of the main drain at different places, and so water the whole at once; but as these favourable circumstances seldom occur, recourse must be had to the floating sluices above mentioned, which must be cut at proper distances, such as 10 or 12 yards, according to the declivity of the land; the catches or frames may be about 30 yards apart.

If the meadow is large, it must be divided into catches or frames, by several carriage gutters, as in fig. 14, and a frame or two watered at a time, according to the body of water which can be commanded; and when the water is withdrawn thence, it may be conveyed to other frames.

In meadows thus watered from springs or small streams, it is of material consequence that the works should be kept as dry as possible between the intervals of watering; and as such situations are not affected by floods, and generally have but little water, they must be rewatered the more frequently; and as the top works of each frame will be in the way of getting more of the water than those lower down, care must be taken to give the latter a longer time, so as to make them as equal as possible.

Flowing meadows described. The other kind of water meadows, viz. those usually called "flowing meadows," require much more labour, and system, in their formation than the foregoing. The land applicable to this purpose being frequently a flat morass, the first object to be considered is, how the water is to be got off when once brought on; and in such situations this can seldom be done without throwing up the land in high ridges, with deep drains between them, as *a*, *b*, *c*, *d*, fig. 15, plate LXIX. A main carriage AB being then taken out of the river at a higher level, so as to command the tops of these ridges, the water is carried by small trenches or carriages along the top of each ridge, and by means of moveable stops of earth is thrown over on each side, and received in the drains below, from whence it is collected into a main drain CD, and carried on to water other meadows, or other parts of the same meadow below. One tier of these ridges being usually watered at once, is generally called "a pitch of work," and it is usual to make the ridges 30 or 40 feet wide; or, if water is abundant, perhaps 60 feet, and 9 or 10 poles in length, or longer, according to the strength and plenty of the water.

It is obvious, from this description, that as the water in this kind of meadow is not used again and again, in one pitch, as in the catch meadows, that this method is only applicable to large streams or to vallies subject to flood; and as these ridges must be formed by manual labour, the expense of this kind of meadow must necessarily exceed the more simple method first described; and the hatches that are necessary to manage and temper the water or rivers, must be much more expensive than those in small brooks.

Management of water meadows. As soon as the aftergrass is eaten off as bare as can be, the manager of the mead, (provincially "the drowner") begins cleaning out the main drain, then the main carriage, and then proceeds to "right up the works," that is, to make good all the water carriages that the cattle have trodden down, and open all the drains they may have trodden in, so as to have one tier or pitch of work ready for "drowning,"

and which is then put under water (if water be plenty enough) during the time the drowner is righting up the next pitch. In the flowing meadows this work is, or ought to be, done early enough in the autumn, to have the whole mead ready to catch, if possible, "the first floods after Michaelmas," the water being then "thick and good," being the first washing of the arable land on the sides of the chalk hills, as well as dirt from the roads, &c.

The length of this autumn watering cannot always be determined, as it depends on situations and circumstances; but if water can be commanded in plenty, the rule is to give it a good soaking at first; perhaps a fortnight or more, with a dry interval of a day or two, always taking the water off at the first appearance of white scum; after which, the works are made as dry as possible, to encourage the growth of grass, and to allow the land to pitch or sink close together.

Whilst the grass grows freely, a fresh watering is not wanted, but as soon as it flags, watering for a few days is necessary. In the months of October, November, or December, some meadows will bear the water for three weeks, which in February or March will not bear it one week, and in April or May not three days.

In all cases where the watering system is undertaken, except in the time of floods, it may be highly useful to disturb the mud and dirt in the bottom of the main carriers, or drains, before watering; a practice frequently adopted on the continent. Lime has also been thrown into these cuts by some irrigating farmers, and raked with a heavy harrow, or other implement at the bottom, which is a process that will be found to add considerably to the manuring quality of the water. It is probable that many other substances might be employed in the same way, and be thus spread over the surface of grass lands in a minute state of division, with vast advantage in promoting vegetation.

The great degree of verdure and luxuriance which almost immediately succeeds the occasional covering of grass lands with water, sufficiently demonstrate the power which it possesses in promoting vegetation. It is a means of fertility that has been employed for ages in more warm climates, with the most beneficial consequences in increasing the quantity of vegetable produce. But though it has been long in use in other countries, and of late more particularly attended to in this, the principle on which it produces its effects does not seem to be fully understood. In speaking of manure as the food of plants, we have already noticed some of the properties of this fluid that may be useful in the vegetable economy when taken up by the fibrous roots of plants; and there are still other ways in which it would seem to be advantageous in forwarding the growth of grass crops.

Winter and spring are the two seasons when meadows are usually watered, as from the month of November till the beginning of March; the experience of the operator can alone regulate this proceeding as to the length of time they should remain under water. In some districts the water is allowed to flow over the fields for several weeks together, with only the interval of a day or two occasionally; in others, the practice is to flood them the alternate weeks. When frosts set in, floating is usually suspended; but it has been remarked, that in such cases the succeeding crop of grass has been abundant. As the spring advances, much less floating is found to be necessary. However, in all cases, when floating is performed to advantage, the meadows should be laid dry between every watering.

Manures. An encreased population requires more abundant stores of food for man, and the beasts immediately under his command, than were before necessary: to this end, where the extension of land cannot be obtained, recourse must be had to the enriching of that which is already in possession, whenever it becomes deteriorated by constant and heavy cropping, with such plants as exhaust the pabulum of vegetables; and also to improve such soils as are by nature less adapted than others to the production of advantageous crops.

Besides the methods we have already spoken of for the improving of lands, mankind have discovered various substances, which, when judiciously applied, possess the power of encreasing the fertility of soil in a wonderful degree. These substances are numerous, and always near at hand. They arise from the decomposition of animal and vegetable matter, and from the agency of fossil and saline substances.

From the changes that are constantly taking place among bodies in nature, and the new combinations which are formed in consequence of those changes, a great variety of matters are unfolded, elaborated, and prepared for the nourishment and support of vegetable life.

Some of the substances which contribute in this way possess considerable fludity and volatility, such as water, and various gaseous materials, as oxygen, hydrogen, azote, and carbonic acid, in different states of combination. While others are more gross and heavy, and require to be applied and incorporated with soils, or spread out upon their surface, in order that they may produce their effects in promoting vegetation. It is principally to these, as being the means of sustaining different sorts of plants as crops, that the term manure has been given by practical writers on agriculture; though it is extremely obvious that they must undergo different changes, and be resolved into their more elementary principles, before they can be taken up, and contribute to the increase and support of vegetables. In the various materials which the art and industry of mankind have rendered capable of being beneficially employed in this manner, there is great diversity; some are found to yield the matters which are necessary for the support of plants much more readily and more abundantly than others, as animal, vegetable, and all such substances as are rich in mucilage, saccharine matters, and calcareous earth, and readily afford carbon, phosphorus, and some aerial fluids; while others that are greatly deficient in all or many of these principles, or do not readily part with them, are found to be of much less utility, when employed in the way of manures. This is probably a principal reason why some sorts of manures or substances, when put upon grounds, are so greatly superior to others, used at the same time, and in the same manner and proportion.

There are, however, many other ways in which substances, when applied to soils, may render them more fertile and productive, and contribute to the aid of vege-

tation. Some, besides furnishing such matters as are suitable for the purpose of promoting the growth of plants, are known to add considerably to the quantity of vegetable and other matters contained in the soils on which they are placed, and thereby provide a more suitable and convenient bed for the reception of the roots of plants; others contribute little in this way, but operate chiefly upon such materials as are contained in them, breaking down their organization or texture, and thus setting at liberty different volatile and other ingredients, by which new compounds are formed, and brought to such states as are the most adapted to the support of vegetable life; others again act principally by producing certain changes and alterations in the constitution or texture of soils, such as rendering them more open and porous, or more stiff and compact, and by such means bringing them into the most proper conditions for the bearing of different vegetable productions; and there are still others that contribute in all or several of these ways at the same time.

Substances of the animal kind, when reduced by the process of putrefaction, or other means, into a soft, pulpy, or mucilaginous state, are found by experience to afford those matters which are suited to the nutrition and support of plants with great readiness, and in more abundance, than most other bodies that can be employed. By chemical analysis it has been seen that the component materials of these substances, so far as agriculture is concerned, are principally water, jelly, or mucilage, and saccharine oleaginous matters, with small portions of saline and calcareous earthy substances. Hence animal matters, though they agree in some circumstances with vegetable productions, each having, in common water, saccharine, and calcareous matters, are far more compounded; and in animal substances, some of these materials are in large proportion, while in vegetables they only exist in a very small degree; and the jelly, which in some measure resembles the gum and mucilage of plants, differs likewise from them, in its having much less tendency to become dry, as well as in its property of attracting humidity from the atmosphere, and of running with great rapidity into a state of putrefaction and decay.

All these principles of animal substances are resolved by their ultimate decomposition into other matters, such as the different gaseous fluids that have been mentioned above, carbon, phosphorous, lime, &c.

Animal substances of every kind, on being deprived of their vital principle, have a quick tendency to take on or run into the state of putrefaction; a process which is considerably affected and influenced by the circumstances under which it is produced. But in the horny and more compact animal matters, this tendency to putrefaction and decomposition is, under similar circumstances, much less rapid than in such as are of a less firm and dense texture.

Hard animal substances. In the matters of this sort that are employed as manures, there is considerable differences in respect to their texture and firmness, some being quite firm and solid, such as bones, horns, hoofs, shavings of horn, and some other similar substances, while others are more soft and pliable. The bones of all animals are capable of affording much nutritious matter to plants, but those which are procured from cattle that have been killed when fat, are the best for the purposes of manure. Those which have been boiled are far inferior, in this view, to those which have not undergone that process, as by such means they are principally robbed of their oily and mucilaginous properties, and consequently must yield much less nourishment to the immediate crop, whether it be grain or grass. All these sorts of substances require to be ground down in mills constructed for the purpose, or otherwise reduced into small pieces, before they are laid on and mixed with the soil. They are excellent for potatoes.

These substances are constituted of a considerable proportion of mucilaginous or gelatinous matter, a slight portion of fat, and an earthy salt composed of the phosphoric acid and calcareous earth. If great heat be applied, they afford a large quantity of hydrogen gas, carbonic acid gas, and a volatile alkaline liquor. From the nature of these different principles, it is evident that some sorts of substances may be blended and united with the reduced particles of bony matters, so as to promote their effects, as manures, in a considerable degree, such as lime, chalk, peat, earth, and good vegetable mould, in suitable proportions, as by such means new combinations may be formed highly favourable to the process of vegetation.

Soft animal substances. There are various matters of this nature that may be of use for the purpose of improving land as manures, some of which have yet been but little attended to by the farmer. Of this sort are greaves, or the residuum which is left after the making of candles, and the scum which is collected in the boiling or refining of sugar.

Different trials with the former have fully convinced us that it is a substance that possesses great powers when employed as a manure. And although it is a substance which is generally procured at a high price, from its going a great way, and being a lasting manure, it may probably be more frequently had recourse to than has hitherto been the case. It is mostly procured in the state of hard compressed square cakes, though sometimes in a soft condition, without having undergone any pressure. When in the former state, the cakes must be broken down and reduced into as great a state of division as possible, which may be rather a troublesome and expensive process, except a mill, or some proper machine for the purpose, be employed. But when it has been even reduced to the finest state possible, it will still be improper for application as a manure, until it has been mixed and incorporated with a pretty large proportion of some rich earthy substance with which it may combine. Excellent for turnips.

A combination of lime and greaves, mixed with mould from the headlands, in the proportion of about 50 bushels of lime to a ton of greaves. This composition resembles sugar scum, which consists of lime and bullocks' blood.

Lime might thus be combined with bones or woollen rags, or with a compost of earth and night-soil; and would certainly greatly facilitate their conversion into manure, as well as render them more active in producing their effects in the support of vegetable crops. And by some of their properties being absorbed by the lime, during the time of their decomposition, and afterwards

parted with more slowly in the soil, they may also by such means be, probably, rendered more durable and lasting, as manures.

There are still more substances of the animal class, such as the blood, serum, wool, hair of animals, refuse of glue-makers, the cuttings of felt-mongers, the clippings of furriers, the scrapings of oiled-leather, and the chips or waste of shoe-makers, which may be made use of as manures, when they can be collected in sufficient quantities. These animal materials, from their abounding in mucilage and oil, their great attraction for moisture, and their being readily soluble in water, contribute quickly to the support of vegetation, but are not probably so durable in their effects upon land as many other substances. Hence they should only be made use of with a view to the immediate crop, which, we believe, is pretty much the case in those places where they can be obtained in such quantities as to be employed for the purposes of agriculture.

Various animal substances of the fish kind, as the blubber remaining after the preparation of oil from the whale, and other large fishes, and different sorts of small fish, both of the shell and other kinds, may be employed as manures; and also the offals of such animals, where they can be procured in a large quantity, as in large towns, sea districts, and where they are cured or prepared in great numbers for the market.

These substances may be readily reduced to that state which is proper for manure, by mixing with them a small portion of the carbonat of lime, and afterwards, according to circumstances, a quantity, two or three times more than the whole, of good vegetable mould.

The refuse of slaughter-houses and butchers' shops may likewise be prepared and made use of in a similar manner to that of fish. For as the manures that are formed from these animal materials are capable of affording much elastic volatile matters during their decomposition, they of course require to be well mixed and blended with such earthy substances as they can combine with, and render soluble, and in proportions suited to their powers, in order to produce the most beneficial effects on vegetation.

Animal dungs. The animalized substances that are, however, most generally made use of as manures, are the excrements of various kinds of animals, which are found in very different conditions, or states of preparation and richness, proceeding in some measure from the kind of food on which the animal has been fed, the matters with which they are incoporated, and the texture of the substances themselves.

The dung of fat animals is unquestionably more rich, and consequently possesses greater powers of fertilization than the dung of lean ones; and that the quality of the dung of every sort of animal will in a great measure be proportioned to the goodness or poverty of its food. Thus, when the animal is fed on oily seeds, such as lint, rape, and others of a similar nature, it will be the most rich; when kept on oil-cake, or those seeds which have been deprived of part of their oily matter, the next so; on turnips, carrots, and suchlike vegetable roots, the next; on the best hay, next; on ordinary hay, next; and on straw, perhaps, the poorest of all.

The urine of animals appears to be a more perfect extract from the animal system than the other; it is therefore surprising that this valuable substance is not more attended to by agricultors. Let it be mixed with the dunghill, or else carted to the field after it has passed through the putrefactive fermentation. Its effect on land is immediate.

Some manures of this kind, such as the soil of privies, is sometimes met with in a state fit to be applied to the ground, when not much mixed with fluid matters, such as urine. It most frequently happens, however, that it is in such a liquid state as to require other more solid substances to be blended with it, before it can be conveniently applied to the soil. In doing this, too little regard seems to have in common been paid to the choice of the most proper materials; but it is obvious, that such as can be most fully acted upon, and the most readily converted into the states suitable for affording the nutrition of vegetables, by the principles of matters thus employed as manures, must be the most adapted for the purpose, as well as the most beneficial. When, therefore, the manure made use of in this way is either wholly or principally constituted of such animalized matters, as from their fluidity are in an improper state or condition to be set on land without having other substances previously mixed with them, such peaty, boggy, or black vegetable earths should be chosen as contain large proportions of matter, which the ammonia or volatile alkali so abundantly provided by the decomposition of such substances may exert itself upon, and reduce into that state of solubility which is suitable for promoting the growth of plants.

The results of experiments attentively made in this way, indeed, clearly demonstrate that an inconceivable loss is incurred by the inconsiderate practice of exficcating human excrement, as well as the negligent custom of permitting the gaseous or liquid parts of dung heaps to evaporate or run away. The trials which we have been enabled to make also lead us to suspect that it is a much more wasteful practice to apply these liquors to ground in their combined state, than in conjunction with such earthy materials as have been mentioned above. Besides, much of them must be imperceptibly carried off by the process of evaporation, even when they are carried out in the most favourable seasons of the year; and they cannot in this way always be made use of on those soils that contain a sufficient quantity of those earthy materials or principles with which they can readily form combinations, and exert their most beneficial and fullest effects. It may be demonstrated, by experiment, that yard and stable dung should be applied to the land in its half decomposed state, and not be suffered to remain in heaps until the putrefactive fermentation has reduced it to over putridity.

We are decidedly of opinion, that the soil of privies is a manure of the most enriching kind, but that its effects are not so lasting as those of many other substances. In some trials which have been lately made with it, it has produced such astonishing fertility, as induces us to conclude that it exceeds all other sorts of manure that can be put in competition with it for the first year after its application. The second is of some service, but in the third its effects nearly, if not quite, disappear. The circumstances which render this sort of manure so imme-

diately active in promoting vegetation, and so quickly deprived of its beneficial influence, would seem to be from the great quantity of elastic principles which it contains in a loose state of combination, and the small quantity of earthy matter which it is capable of supplying to the soil, by the last stages of decomposition or decay.

This view of the nature of the manures afforded by different animals, should lead the practical agricultor to be more attentive to the subject, in order that he may render them more abundant, and be capable of employing them under the most favourable circumstances, which cannot be the case while they are, as at present, indiscriminately mixed and blended in the common dung-heap.

It is, however; from the larger animals that the farmer derives the principal part of the dung that is made use of as manure, in the cultivation and improvement of land. The dung of such horses as are highly fed being found, as has been already seen, to be much more valuable for the general purposes of agriculture, and some uses in horticulture, than that which is made by horses when fed with hay or grass only. Where the animals are kept in the latter way, it is probably not so good as that of well-fed cows and neat cattle in general, as in these it may, perhaps, become more animalized from the circumstance of their food being more intimately blended with the saliva, or other juices, during the ruminant state of feeding in such animals. The dung of horses is, however, in common much more disposed to the process of putrefaction, and cause more heat, than that of cows and other neat cattle; and indeed these are the chief distinguishing circumstances between them as manures. The dung of neat cattle may also, on account of its less disposition to run into the state of putrefaction, contribute more of the earthy material to the land on which it is applied. Hence, probably, its superior utility on the leaner and poorer or thinner sorts of soil. The dung and urine of animals when newly voided are not, except when the animals are morbid, in a putrescent condition, the length of time in which they remain in their bodies being too short for its fully taking place; but some degree of, or tendency to, putridity is constantly necessary to their discharge.

From the experiments that have been made with the dung of sheep, it is evident that it is equally valuable with that of many other animals that feed in the same way, but agriculturists have not yet turned their attention sufficiently to the means of collecting and preserving it, so that it may be used alone as a manure. The method by which it is at present applied to land is by folding the animals upon it, under which method of management, on many soils, a great part of the advantage must be derived from the operation or action of the ammonia of their urine upon the vegetable matters contained in them, as well as from the consolidation produced by their treading. It is well known that the urine and dung of sheep want no fermentation previous to its being applied to the land; the sooner therefore the seed is sown after folding, the greater is the effect.

Vegetable, as well as animal substances, when deprived of their vital principles or life, are soon rendered fit, by the separation, reduction, and ultimate decomposition, of their constituent principles, for the nourishment and support of new plants. This process is greatly promoted, in all kinds of substances, by the materials being exposed to the free influence or agency of atmospheric air, moisture, and a midling degree of heat; various matters are set at liberty, by which different new combinations take place, that are capable of promoting vegetation in different degrees, and upon which their utility as manures, perhaps, chiefly depends. The stages of this decomposition have generally been supposed regularly to succeed one another, from that which is productive of sweetness, through the vinous and acetous, to that which is the ultimate result of putrefaction. Different sorts and parts of organised matters, when dead, undergo many different sorts of chemical changes, which are different according to the degrees of heat, the quantity of water, and of air, to which they are exposed.

In the vinous fermentation or process which commences after the saccharine, carbon becomes united with pure air in a large proportion; and it is probable that, at the moment of their combination, while they are in the form of a liquid, and before they assume the gaseous state, they may be taken up by the roots of vegetables.

The substances of the vegetable kind that may be advantageously converted into manure are so extremely numerous, that it is impossible within our limits to describe them. All kinds of green vegetable productions may be employed in this way; such as the luxuriant weeds of rivers, lakes, ponds, and ditches; fern, and the refuse of different kinds of garden vegetables. Where green materials of this nature are made use of, they should always be cut down while in their juicy state, just before their flowers begin to appear, in order that they may be in the most suitable condition for becoming quickly putrid, and to prevent the injury that might otherwise be sustained from the vegetation of their seeds. They are afterwards to be collected into heaps of a moderate size, and their putrefaction promoted by their being thrown together as lightly as possible, and the occasional sprinkling of them with water, if the season be hot and dry; and as lime is found, when applied to vegetables in their green moist state, to disengage from them both hydrogen and azote, by the combination of which volatile alkali is produced, it may be advantageous to blend a portion of lime at first with the heaps, and afterwards add a suitable quantity of peat earth, or good vegetable mould, for the alkali thus formed to act upon. By this method, the quantity of manure from such substances may be greatly augmented, and rendered more valuable. But when dry materials, such as hay, straw of different kinds, fern, and rushes, such additions cannot be had recourse to with equal success, unless where much of the dung and urine of animals have been incorporated with them; but their resolution and decay may be greatly promoted by their being kept in a state of moisture, without the water being suffered to stagnate upon them, and by their not being permitted to be trodden down too much by cattle, or other means, in the farm yards.

Another beneficial means of vegetable manure, which is yet far from being sufficiently practised, is that of providing full crops of succulent green vegetables, such as clover, buck-wheat, tares, vetches, spurry, pease, beans, turnips, and many other similar plants, to be turned

down by the plough, in order that they may undergo the putrefactive process under the ground, and by that means be converted into manure, and supply the nutrition of plants.

Sea-weed is another vegetable production which is capable of being employed as a manure with great advantage, and should never be neglected where it is within the reach of the farmer. In some places it is the practice to spread it upon the lands as soon as possible after being cut from the verges of the rocks on the different sea coasts, or collected after being left by the tides, and to plough it in where this method is adopted, as little time as possible should be suffered to elapse after the cutting or collecting of the weed, before it is ploughed down; for as the plant in its green or succulent state readily decays and becomes putrid, if there be any considerable delay in the performance of the business, especially when the weather is hot, much of its valuable properties as a manure is dissipated, and carried away by means of evaporation.

Bark, which has been made use of for the purpose of tanning leather, may likewise be employed as a manure: when used in this way it should be collected into moderate sized heaps, before it has become dry by too much exposure to the heat of the sun and wind; and then by having a quantity of lime mingled with it, and being kept slightly moistened with water, its putrefaction and decay may be greatly promoted.

The mud taken from the bottom of rivers, ponds and other places where water has stagnated for some length of time, fresh or maiden earth, and the scourings of old ditches, are substances that may frequently be employed with advantage as manures, being principally composed of the recrements of decayed vegetable matters. They should not, however, be put upon grounds, especially those under grass, until they have been reduced into a considerable degree of fineness, by means of frequent turning over, and the mixing of a portion of lime, rotten dung, or other materials of the same kind, with them, in order to promote and render the decay of the more solid parts more full and complete.

Substances of the calcareous kind, which are to be considered under this head, produce effects more or less powerful in promoting the growth of vegetable crops, in some measure, according to the state and quantity in which they are applied, the nature of the soils on which they are employed, and the properties of the matters with which they are combined.

Substances that contain much saline matter in combination with their earthy and other ingredients, are found, in many instances, when properly employed as manures, to contribute greatly to the support of vegetation. The materials principally made use of in this way are the refuse of different manufactures, such as bleaching and soap-boiling, where they can be procured in sufficient quantities, as in the vicinity of large towns, and where such manufactures are carried on in an extensive manner; the ashes remaining after the combustion or burning of various green vegetable matters, wood, pit-coal, peat, &c. and some other substances, such as soot and sea-salt.

It is most probably to the different alkaline principles contained in these substances, from the great facility and power which they possess of acting upon and dissolving the parts of animal and vegetable matters, especially such of the latter kind as have been rendered insoluble by the absorption of the oxygen, or pure air of the atmosphere, from long or frequent exposure to it, that their beneficial effects as manures are chiefly to be ascribed.

But these substances, besides their forming in the soils, or the earthy materials with which they are mixed, such compounds as are beneficial in promoting the growth of vegetables may be useful in many cases when properly applied, and used in sufficient quantity, in correcting acidity, in altering the state or condition of the lands, as by the taking away of moisture from the surface where it prevails in an over-proportion in meadows and pastures, and thereby supports crops of coarse vegetables, and by rendering the texture of such grounds as are under the plough more open and friable, consequently more suitable for the reception of the roots of corn crops.

It is evident, from what has been already observed on the nature of the different substances that are capable of being made use of as manures, that they may frequently be mixed and blended with each other, or with substances of other kinds, and by such means be not only considerably increased in quantity, but in many cases rendered more effectual and more suitable for application than in their simple states; but at the same time, that some of them may be mixed and incorporated in this way with much more advantage than others; for though the general experience of farmers has fully shown the great importance and utility of employing compound manures, or composts, little attention has till lately been paid to the compounding or mixing together of such substances as are, from the principles which they originally contain, or which are formed from them in the changes which they undergo in the different stages of their decomposition, adapted to act in the most suitable manner for producing such combinations or alterations in the materials as are capable of being beneficial in the promotion of vegetation when they are employed as manures.

Farm-yard manure, which is the most general application of any, from its being formed by the decay of various kinds of vegetable matters, such as hay, straw, fern, and many other materials of a similar nature, with which the dung and urine of animals is incorporated and combined, must be considered as a compound substance. And from the large proportion in which such vegetable productions enter into its composition, and the quantity of earthy materials that is in most cases, especially where the management is upon a judicious plan, added by the laying of suitable bottoms, it is not so frequently necessary to be blended with other substances that are usually employed in forming composts. But from most of the vegetable materials that constitute the chief part of this sort of manure, being made use of in a dry and hard state, they do not so quickly ferment or run into the state of decay, notwithstanding the proportion of animalized matters that may be mixed with them; it therefore becomes an useful practice to turn them over, by which their complete putrefaction may not only be promoted, but the different materials be more minutely blended together, on both which accounts they may become more useful when applied as manure upon land. In the forming of this manure, care should also constantly be taken that the heaps be so situated as that they may not become too dry, or too

much soaked in water, as in either case they must be greatly injured. Whenever it may be requisite to incorporate any earthy material with this sort of manure, the agricultor should always carefully attend to the state or richness in which it may exist in the yard, and proportion such additions accordingly. It will, however, never demand nearly so large a proportion, as such manures as consist almost wholly of animal matters.

Where animal matters are collected and thrown together in any quantity, there can be little doubt but that a great increase of good manure may be provided by mixing with them, as has been already observed, rich surface-mould, peat-earth, or the scrapings of old ditches and roads; as by such a practice the ammonia formed during the decomposition of the animal substances is prevented from escaping, as would otherwise be the case, which, by combining with and acting upon the earthy materials, quickly renders them proper for the purposes of manure. As substances of the animal kind have been shown to run very rapidly into the state of putrefaction, they may frequently be incorporated with such vegetable materials as are little disposed, or with difficulty made, to rot or become putrid, and by such means useful composts be more expeditiously formed. In making use of such earthy substances as have been mentioned, it may be of much advantage to have them exposed to the influence of the atmosphere for a considerable length of time, frequently turning them over, before they are mixed with the manures, as by such means they become in a more pulverized state, and are capable of being more intimately blended with such materials, and afterwards spread over the land with much greater equality, a circumstance upon which their effects very much depend. If, in performing this business, the earthy substances be formed into a sort of ridge, about five or six feet in height, and nearly the same breadth in the bottom, they will be in the most proper situation for being united with dung, or other matters that may be employed.

In the application of manure to land, several circumstances are necessary to be considered, such as the state or condition of the substances which are to be made use of, the nature of the soils on which they are to be laid, the kind of crop that is to be promoted by them, and the season in which they are put into or upon the ground.

As we have already seen that changes are continually taking place from the moment the materials of the dung-heap are thrown together, to the period in which they are reduced into a black carbonic earthy matter; and that in most of the different stages through which they pass in this process of decomposition, such substances are formed as are capable of contributing to the nutrition and support of vegetable crops; it seems probable, that in cases where manures are to be turned into the ground, and such crops cultivated as require a supply of nourishment for a considerable length of time, they should be employed in their long or more imperfectly reduced states, as by the heat which is evolved in the commencement of their dissolution, the process of early vegetation may be greatly promoted, and their gradual decomposition and decay afterwards, under the ground, afford a more durable and regular supply of nutrient materials, and thereby contribute more effectually to the growth of the crops; but that where they are to be buried in, or applied to, the surface of the soil, and intended merely for the benefit and support of such crops as are of short duration, or quickly arrive at their full growth, they may be more advantageously made use of after they have been more fully and completely reduced, as in this state the manure is, in the case of grass lands, not only capable of being spread out in a more regular and uniform manner, by which it becomes more evenly as well as more generally carried down to the roots of the plants by rains, but it is in the most suitable condition for allowing the young plants the means of springing up with facility, and at the same time, whether used under or upon the soil, of affording the crops that abundant supply of nourishment which is necessary to their speedy growth and luxuriance, and by these means to contribute the most perfectly to the promotion of their increase.

And as in the slow and gradual decomposition of the materials which are made use of for manures, when slightly deposited beneath the soil, there is much less waste of heat and those elastic matters which contribute so greatly to the support of vegetation, than where they are made to undergo the various processes of dissolution in large masses, as in dung heaps, they may probably sometimes on that account be most advantageously employed in this state.

On this principle too the ploughing down of fresh vegetable crops, in many cases, in their most succulent states, may be a more economical as well as more beneficial practice; especially in such light and dry kinds of soil as will more readily admit of their gradual putrefaction and decay, than to cut and take them off for the purpose of being by other means converted into manure. It seems likewise probable, on the same grounds, that for the production of crops of bulbous-rooted vegetables on the more stiff and tenacious soils, the matters made use of as manures may be employed with the greatest advantage, when put into the earth before they have undergone any great degree of decay by means of putrefaction, as in this way there is no waste, the whole being ultimately converted and applied, though more slowly, to the support of the crops.

As to the season in which manures may be put into the soil, or spread out upon its surface, with the greatest benefit and advantage, though in practice it must, in some measure, depend on the state of the land and the convenience of the farmer, it should, in cases where they are buried in the ground, be as nearly as possible to the periods in which the seeds or roots which they are designed to support, are sown or placed in the earth; and in the latter case, or where they are to be laid upon the surface of the land, it ought to be just before the crops of grass, or other vegetables, begin naturally to spring or shoot forth.

And by the application of such manures as are employed in the way of top-dressings in the beginning of spring, they are laid on in the most favourable period for affording their nutritious principles, and for their being drank up by the roots of plants, consequently become useful at the time they are most wanted for the promotion of the crops, and the great waste which must otherwise be caused, either by the excessive falls of rains and floods in the winter season, washing down much of the valuable properties into the adjoining rivers and ditches, or the eva-

poration of their more volatile or elastic matters by means of the summer heats, is most effectually guarded against and prevented.

On all these accounts, therefore, farmers should contrive as much as possible to apply the manures, intended as top-dressings to grass lands, as early in the spring as it can be conveniently done. which may be easily managed on those that are dry, and on such as are inclined to be wet and poachy, it may probably be greatly facilitated by having small light carts constructed for the purpose, and placed on broad cylinders as wheels.

In the application of manures to lands under tillage, as well as those in the state of grass, there are a few other circumstances that require the attention of cultivators; such as the depth they may be deposited in the soil, the modes of putting them upon the ground, and the most economical methods of employing them.

In respect to the advantage of using one sort of manure in preference to another, it may be observed, that as animal matters are found in general to undergo more speedily the process of putrefaction or decomposition, than those of the vegetable kind, and as in most instances they afford those mucilaginous and elastic principles that contribute so largely to the support of vegetable life in greater proportions; such manures as are either wholly or in a great measure composed of them, must be the most beneficially employed, where quick and abundant supplies of nourishment are required, as in the growth of all the more gross and luxuriant crops, whether of grain, plants, or grasses; and that as those vegetable substances which contain saccharine, farinaceous, oily, saline, or mucilaginous principles in the largest quantities are ascertained from experience to proceed the most readily into the state of dissolution or decay, and consequently to afford more fully and more expeditiously the nutrient food of new plants, where manures are principally formed from them, they should be preferred to such as have been made from the harder and more ligneous vegetable substances, that contain such properties in scarcely any, or much smaller degrees, for all the purposes, of agriculture.

Of the natural spontaneous grasses. Having thus stated the nature and principles of the various soils which are met with on the surface of the earth, and shown the different modes of improving the same, it becomes us, in the next place, to speak of the best natural productions thereof, especially of the gramina kind; that from thence the agricultor may make his selection of such land as may be most profitable.

In our meadow and pasture lands we find a great variety of grasses, of which some are far more valuable than others; to know the good from those which are indifferent becomes the interest of the farmer; we therefore give him the charactes (accompanied with figures. See plates LXVIII and LXIX) of the most valuable, so classed in our catalogue as they stand in precedence of quality one to another.

1. Great smooth stalked meadow grass—Poa pratensis.
2. Hard fescue grass—Festuca duriuscula.
3. Meadow fescue grass—Festuca pratensis.
4. Ray grass—Lolium perenne.
5. Meadow fox-tail grass—Alopecurus pratensis.
6. Sheep's fescue grass—Festuca ovina.
7. Compressed meadow grass—Poa compressa. [Blue Glass.]
8. Rough stalked meadow grass—Poa trivialis.
9. Marsh meadow grass—Poa palustris.
10. Crested dog's tail grass—Cynosurus cristatus.
11. Knotty cat's tail grass—Phleum nodosum.
12. Sweet scented spring grass—Anthoxanthum odoratum.

Great or smooth-stalked meadow grass. This grass is considered as the best of all we have; it is early in its foliage, makes the best hay, affords the richest pasture, all sorts of cattle are fond of it, it is in all our meadows, and will continue in the same land much longer than any other grass.

Hard fescue. This is an early and productive grass, with fine foliage, which grows well on downs and rich meadows. It is well adapted for being combined with other grasses in forming sheep pastures, and stands high in esteem as a very good hay grass.

Meadow fescue grass. This is a grass that comes near in its appearance to ray grass, but to which it seems greatly superior, as being larger and more productive of foliage. It is strictly perennial and hardy, thriving well in moist soils, growing in all situations; and it abounds in the best meadows, in the best hay districts; is sweet, luxuriant, and quick of growth, affording rich pasture, and making good hay. In short, it seems well calculated to supply the deffects of ray grass. Besides, it has the quality of producing more seeds than most of the other sorts of grasses, which are easily gathered, and grow readily.

Ray or rye grass. This is a sort of grass that has been much in cultivation, but is deficient in some of the properties necessary for meadow or pasture lands. In rich moist meadows its foliage is abundant; and it seems probable that it is highly acceptable and nutritious in feeding cattle; its foliage is of rapid growth, and flowering stems continually shooting forth. It is best adapted to the loamy and sandy descriptions of soils; but it will succeed on any except stiff clay, and even on that it may be grown.

On converting ray grass into hay, it is necessary to cut it at a period previous to its being so ripe as to have perfected its seed, and changed to a yellow colour; for in this case a great part of the juices of the plant, which constitute a principal part of the nutriment it is to afford, will be converted into a species of straw, and its nutritive properties, be proportionably diminished.

Meadow fox-tail grass. It is in some measure distinguished by the largeness of its foliage, which is rather coarse, and by its producing a soft spike on a long stalk, early in May. If it be mown early, just as it comes into bloom, the hay will not be coarse. It shoots very rapidly after mowing, and produces a plentiful aftermath.

Sheep's fescue. This grass is praise-worthy both for the purposes of pasture and hay; sheep and other sorts of stock are fond of it, and are soon rendered fat in pastures where it prevails, giving to mutton a sweet delicious flavour.

Rough-stalked meadow grass. It delights in moisture, and situations that are sheltered; on which account, though there are few more productive, or better adapted for the purpose of hay or pasturage, it is tender, and liable to be injurd, by severe cold or drought; and in moist rich

ground it has been observed to grow tall, while in poor land it has been found equally diminutive. It is a grass well adapted to good, sound, moist loams. The produce is admirable for the feeding of all sorts of cattle.

Marsh meadow grass. This is a fine exuberant grass, and one of the best dairy grasses we have. It grows in all our rich marches, which are subject to be flooded in the winter; generally four feet high. Its panick, when full-blown, is wonderfully fine and flowing.

Compressed meadow grass. This is an excellent grass for parks and sheep walks, deer and sheep being fond of it; and as it is a dwarf grass, the blades seldom exceeding two inches, it makes a fine turf, and renders the flesh of the animals short, and sweet flavoured.

Crested dog's tail grass. This is a grass that is a favourite and wholesome food for sheep. It grows best in dry pastural lands, and will not thrive in meadows that are very moist. It abounds greatly in the best pastures, and is a blade grass that shoots up the first after the land has been mown; its thickest tufts afford much food for sheep in the time of snow and severe weather in the winter season. From the rapidity of its growth it may be apt to get coarse, if not cut down more quickly than is often the case.

Knotty cat's tail grass. It is a fine exuberant grass, very fit for dairy pasture and for cow-hay. It produces much rich milk, and kine are fond of it.

Sweet-scented vernal-grass. This is a sort of grass that comes early into blossom; and is also valuable for its readiness to grow in moist kinds of soil and situation, but in point of crop it is not so productive as some others; and it is well known to be the only grass of this climate which is odoriferous; the agreeable scent of new-made hay being produced almost entirely by it; and the green leaves, when bruised, readily impart this odour to the fingers, by which means the foliage may constantly be known.

Cultivation of grass lands. Lands in the state of grass must obviously be applied to different purposes, according to their nature, situation, and other circumstances. Those which are of the more moist kinds, whether from the nature of the soil or the peculiarity of situation, are for the most part kept under the scythe; while those of the contrary description, that are situated at a greater height, and of course, in most cases, possess a greater degree of firmness, are in general appropriated to the purpose of pasturage: though, in particular situations, where grass land is scarce, and consequently of great value, it is good management to convert them occasionally to the purpose of hay.

Meadow lands, from their being situated in the hollows and sloping sides of the valleys, where the staple and depth of soil of the lands have for a long time been continually increasing by the deposition of various sorts of vegetable and other matters brought down from the higher grounds, are, however, in general, in a considerably greater state of fertility, and evidently better fitted for the permanent production of grass than those from which they have derived their richness.

Management of meadow lands. From the greater retention of moisture in the vale land, in consequence of their situation, and the depth of vegetable matter, they are liable to throw up coarse herbage in many cases· more drainage, as well as other management, is necessary to bring them into the proper condition for the growth of good herbage, than is requisite in the hay grounds in the more elevated places. And by a more particular attention in these respects they would, in many instances, be rendered a vast deal more productive than they are at present, and at the same time afford a much better herbage. They would also admit stock upon them a much greater length of time, both in the autumn and spring seasons.

The most proper season for surface-draining grass lands is in the autumn, when they are somewhat firm and dry, as in the early spring months such lands are too full of moisture. The grips, or small open drains, should be cut obliquely, in the most suitable directions for conveying off the superficial stagnant water, the materials taken out being wholly removed. Much of this sort of draining may be performed at a small expense, and the beneficial effects be very considerable.

Meadow lands also demand much more attention in their management than those which are fed by cattle. In all cases stock should be turned upon the lands, and manures applied with much care, and only when the land is in such a state of dryness as not to be injured by the poaching in or breaking of the sward.

It must be evident, that the breaking of the surface, texture, or sward of grass lands must in all cases be prejudicial, not only by the destruction of plants, which is thereby immediately produced, but also by the retention and stagnation of water upon them in the holes and depressions from small portions of the turf being forced in.

The most proper periods of shutting up such grass lands as are designed for hay must, like those of eating them down in the autumn by stock, depend on various circumstances that can only suit the particular cases. In general, however, it is the best practice not to delay it too long. When the lands are not eaten at all in the spring by cattle, after the sheep have been removed about the middle of February, nothing further should be allowed to enter the meadows; by which means a quick vegetation is secured, as well as a more plentiful crop and a more early hay harvest. And in other cases, when eaten too late, there is not time for the grass to produce a full crop before the commencement of the hay season; of course the farmer sustains more loss than can be repaid by any advantage in the additional feeding he may obtain. This is therefore, the best practice where the view of the farmer is hay; and it should be particularly adopted and attended to in cow farms, where it is of much importance to cut early, to secure hay of a fine, grassy quality, for the purpose of producing large supplies of milk.

After the meadows or other grass lands have had the cattle and other sorts of live stock removed from them in the early spring months, and been shut up for hay, they should be prepared for the scythe, by having all sorts of obstructions picked up and removed. This work should always be executed as soon as possible, before the grass begins to spring up too much and conceal them, as it is difficult to perform the business effectually afterwards.

It is an excellent practice to have all sorts of coarse plants of the aquatic and other kinds, such as rushes, fern, docks, thistles, and various others, effectually drawn up and eradicated both from the hedge-rows and other parts of the fields, in order to prevent their running up to seed and disseminating themselves over the lands.

Mowing of hay lands. In the cutting of grass crops for the purpose of being converted into hay, it is necessary that they be in the most suitable states of growth and maturity for affording the best and most nutritious fodder. With this view, it would seem that they should neither be cut at too early a period, nor suffered to stand too long; as in the former case there will be considerable loss in the drying, from the produce being in so soft and green a condition, and in the latter from a large proportion of the nourishing properties being expended. It is probable, therefore, that grass, when mown before it becomes in full flower, while the rich saccharine juice is in part retained at the joints of the flower-stems, is in the most proper condition for being cut down, as at that period it must contain the largest proportion of nutritious material, but which then begins to be absorbed and taken up in proportion as the flowers expand and the seeds ripen.

But there are other circumstances besides those of ripeness to be attended to in determining the period of cutting crops of grass; as in some cases, where they are thick upon the ground, the bottom parts become of a yellow colour before the flowering fully takes place: under such circumstances, it will always be the most advisable practice to mow as soon as the weather will possibly admit; for if this is neglected there will be great danger of its rotting, or at any rate of its acquiring a disagreeable flavour, and of becoming of but little value. Where grass is very tall, as is often the case in moist meadows, it is liable to fall down and lodge, by which the same effects are produced. In this case also the mowing should be performed as soon as possible.

In the operation of mowing, the chief art consists in cutting the crop as close to the surface of the ground as possible, and perfectly level, pointing the swaths well out, so as to leave scarcely any ridges under them.

Hay-making. The great art in converting grass into hay consists in rendering it sufficiently dry to prevent its fermentation taking on too great a degree of heat in the stack or mow, and at the same time preserving a large proportion of the natural juice of the plants. Where this medium can be attained with the most exactness, the best and most nutritious hay will be produced.

In the making of hay, some attention should be paid to the quality of the soil and the kind of herbage growing upon it. The hard benty hay of a poor soil is in little or no danger of heating too much in the stack; it should, therefore, be put very early together, in order to promote a considerable sweating, as the only means of imparting a flavour to it, which will make it agreeable to horses and lean cattle, as it will be nearly unfit for every other sort of stock. It is the succulent herbage of rich land, or land highly manured, that is most likely to generate too great a degree of heat; of course grass from such land should have more time allowed in making it into hay. In moderately hot seasons the proper ground point of drying may be easily judged of; but when they are very hot and scorching it is easy to be mistaken; as in such weather the grass becomes crisp, rustles, and handles like hay, before the moisture or sap is sufficiently dissipated for it to be in a state fit to be laid up in large stocks. If that, however, be done when it is thus insufficiently made, it mostly heats too much, becoming mow-burnt in some cases.

The art of hay-making much depends in the due observance of the following rules, as nearly as circumstances will admit.

In the first day's process all the grass mown before nine o'clock in the morning must be tedded or spread out, great care being taken to shake it so as to leave it free from lumps, and to strew it evenly over the whole surface of the ground. It is soon afterwards turned, with an equal degree of care and attention; and if the number of hands be sufficient, they turn the whole again, or at least as much of it as they can before one o'clock. It is then raked into what are termed single windrows, or so as that each person may form a row at about three feet distance; and the last operation of the day is to put it up into grass cocks. The business of the succeeding day commences with the process of tedding all the grass that was mown the first day after nine o'clock, and all that was mown the second day before the same hour. The grass-cocks are then well shaken out into separate plats of five or six yards in breadth. The plats are next turned, and after that, the grass that was tedded in the first part of the morning once or twice, in the same manner as described in the first day. This business should all be performed before one o'clock, that the whole may lie to dry while the people are at dinner. After this the first thing is to rake the plats into double windrows, which is done by every two persons raking the hay in opposite directions or towards each other, forming a row between them of double the size of the single windrows, each being about six or eight feet distant from the other. They afterwards rake the grass tedded thus into single windrows; then put the double windrows into bastard cocks; and conclude by putting the single windrows into grass-cocks. The labour of the third day is begun by first tedding and spreading out the grass mown and not spread the preceding day, as well as that mown in the early part of the day, and then the grass-cocks are thrown out into plats as before, and the bastard cocks into plats of less extent. These narrow plats, though last spread out, are first turned, then those which were in grass-cocks; and lastly the grass is turned once or twice before one o'clock. When the weather has been sunny and fine, the hay which was last night in bastard cocks will this afternoon be in a proper state to be carried, as in fine seasons it may mostly be performed on the third day; but when the weather has been cool and cloudy, no part of it probably will be fit to carry. In that case, the first business after dinner is to rake that which was in grass-cocks last night into double windrows; then the grass which was this morning spread from the swaths into single windrows. After this the hay which was last night in bastard cocks is made up into full sized cocks, and care taken to rake the hay up clean, and also to put the rakings upon the top of each cock. And lastly, the double

windrows are put up into bastard cocks and the single ones into grass-cocks, as in the preceding days. On the fourth day the great cocks thus described are mostly carried before dinner. The other operations are similar to those of the former days, and proceed in the same order, continuing them daily until the whole is finished.

During the whole course of hay-making the grass should, as much as possible, be protected both in the day and night against rain and dew, by cocking.

The preserving hay of a proper green colour is a circumstance of some importance. In order to effect it, the bastard cocks, previous to their being carried, should be put up in the heat of the day, and remain in that condition till the following morning, when they must be turned and opened so as to dispel any damp that might induce it to heat in the stack, and in that way spoil the colour. The acquisition of a lightish brown colour in the stack is not found injurious to hay, but where it becomes of a dark brown from too much heat, it is said to weaken and relax horses that are fed upon it by its powerful diuretic quality. It is of course of inferior value for that purpose, but not the worse for fattening cattle with.

For the purpose of facilitating the business of getting the hay together in bad showery seasons, hay-sweeps have been constructed.

A contrivance of the first sort has been invented, and described in vol. xiv. of the Transactions of the Society for the Encouragement of Arts, Manufactures, &c. It is so constructed as to be drawn by four horses in pairs, but smaller ones might be made to be drawn by two, and is managed by two boys, one of whom drives each pair of horses, being mounted on one of them. Where the ground is level, little more will be necessary in order to assist the machine, than merely to break and turn up the rows of hay in different places. In catching or showery weather, such a machine may be particularly useful, in getting a field of hay, nearly dry, into large heaps in different parts of the field, whence it may be made into large cocks of half a ton or more each, with the utmost facility.

Stacking and thatching hay. The form of the hay stack is not a matter of much consequence, the long square, or oblong shapes are the most safe and convenient, especially when not too broad, as they admit the air the most fully. But the circular form for farm use, where straw is scarce, may be the most advantageous in the economy of straw in thatching.

The size of the staddle or stack bottom should be proportioned to the quantity of hay, but it is better not to have the stacks too large; 24 feet by 14 or 15 is for most occasions a good size.

The business of stacking hay is best performed, if possible, while there is a full sun, as by such means it is much improved. It is necessary to have a person that understands the art of setting up stacks, and a sufficient number of helpers to assist in spreading the hay and treading it well down. In building, the middle of the stack should always be well kept up, something higher than the sides. Where work of this sort is well executed, at leisure times, during the whole period the stack is building, the men are employed in pulling the sides and ends into proper form.

After the work of stacking has been completed, and the stack is pulled and topped up, it is left till it has sweated, and is perfectly settled, which is mostly the case in a week or ten days: the roof should then be well covered by a good coat of thatch. The roof should be dry when the thatch is put on, to prevent the hay from becoming mouldy. It is of great consequence that this sort of work be well performed.

It is a point not perfectly decided among agricultors, whether hay keeps better in stacks in the open air or in barns for the purpose. It is the opinion of most farmers that the first mode has the advantage in so far as respects the quality of the hay.

After-grass. Where after-grass is fed off by stock, there is much difference of opinion in regard to the most proper periods of turning in the animals. Some have contended that it is the best practice to let them into the field before the young grass has attained any very great head; while others maintain the opposite doctrine, and think it the best method to allow the grass to get up to a full bite before the stock is turned upon the land. Both endeavour to support their opinions by experience. But as they cannot be both of them true, it is probable that the extremes of each are to be avoided; and that, as in many other matters, the truth may lie in the middle. This is indeed equally supported by fact and the observation of the most intelligent managers; as when the cattle are turned in too early there is not a sufficient bite to keep up the condition of the animals; while in the contrary extreme, the stock so soon fill themselves, that much of it is trodden down and wasted afterwards in their roaming about the fields to pick the sweetest morsels.

Where much stock is turned upon after-grass in a full state of growth, there cannot be any doubt but that much loss must, as has been just observed, be sustained by the treading down and rendering the grass unfit for being eaten off. It is therefore perhaps only by beginning the pasturage of after-grass when in the middle state of growth that it can be consumed to the best advantage, and without loss in either of the ways that have been just noticed.

In the stocking of after-grass, some attention is necessary not to have too great a number of animals on a given proportion of land. One cow to the acre on well-grown after-grass is an ample stock. Good grass-land may, however, admit something more.

Management of pasture lands. Having explained the different methods of management that seem necessary to the cultivation of those sorts of grass lands that are chiefly applied to the purpose of producing hay, we shall now describe the modes of practice which appear requisite in such as are almost wholly appropriated to the support and fattening of live stock.

The grounds that are the most perfectly adapted to this use are, all those which have a considerable depth of good mould, and at the same time that they afford a good herbage, are so dry in their nature as to admit the animals to feed upon them at almost all seasons without injury by poaching. Coarse rushy lands may, however, in many cases be converted into good pastures, by proper attention in draining, and cutting over the rushes in the early part of the spring, and about Midsummer, as by these means the plants decay, the young shoots

being afterwards eaten by young stock, and the good grass plants allowed to flourish.

Pasture lands should likewise, as much as possible, possess properties in the nature of their grasses that are the most advantageous for the particular method of management under which they are to be conducted. In this view, some may be more adapted to the producing of milk or butter, others of cheese, and others again of feeding or fattening animals. It is in some measure on this account, as well as that of local convenience, that different modes of management are employed on grass lands.

The difference of situation in pasture lands has likewise much influence in directing the uses to which they may be applied with the greatest benefit. The higher or more elevated grounds being in general more proper for sheep, while those of the lower and more inclosed kinds are mostly better suited for the purpose of neat cattle or other animals under the fattening system.

Pastures, when not well attended to, are frequently prevented from being properly fed, by various kinds of low shrubby plants, such as those of the alder, brier, broom, furze, and other sorts that shoot out upon the surface; these which should always be extirpated as soon as the business can be conveniently done; as by their remaining upon and shading the ground they render the herbage sour, and improper for the food of cattle. This sort of work may be performed by cutting them closely down as they rise in the early spring months; but a better practice is to dig them completely out.

Where pastures are productive in grasses of the more sharp coarse bladed kinds which rise into tufts or tussocks, and which are known to agricultors under the titles of pink or carnation grasses, it is a certain indication that the soil is too retentive of moisture, and stands in need of draining.

The improvement of the fertility of pasture grounds may be effected in different ways, as either by the direct application of manure in its natural state, such as that of rotten dung, lime, marl, or in that of earthy compost, occasionally, over their surfaces in a thin even manner; or indirectly by the folding or confining of sheep upon the land during the time they consume other sorts of green food, such as turnips, &c. The latter mode is unquestionably the most advantageous and convenient, as it is in but very few situations that the former can be practised without robbing the arable or hay lands of their property.

In explaining the methods of management that are necessary in the cultivation of arable lands, in order to afford a suitable state of soil and nourishment for the growth of grain or other crops, it will be proper to consider them as relating to grounds that have not yet been brought under the plough, and such as have been already in the state of tillage.

Removing obstructions to tillage. In the first place, the removing of stones, the eradicating of wood, the destruction of different sorts of plants, and the removal of such degrees of wetness as may be injurious, before the business of ploughing or loosening the mould of the soil can be properly carried on. The stones that oppose obstruction, in this view, are principally either such as are met with in a loose state in the ground on its being ploughed, or such as are fixed in the soil, and incapable of being removed without much labour and difficulty. Some of these last are often of such a size as to present themselves upon the surface, and cause much land to be lost, by their not permitting the plough to come near them. Those which are concealed below the surface are, howhowever, the most detrimental, as the implements are frequently destroyed, and much inconvenience experienced from them, before they can be perceived by the ploughman, though he may be perfectly attentive to the circumstance.

In all cases, land should be as much as possible cleared from such stones as retard or prevent the operation of the plough before the business of tillage be undertaken; as without due attention in this respect considerable loss may be sustained by the breaking of implements, and the great delay that must take place in the work.

In the clearing of lands from wood, different methods must be pursued, according to the nature of the wood with which they are covered. Where there are large trees of the timber kind, they should be completely grubbed up at a proper season of the year, care being taken that the roots be as much as possible removed.

In cases where broom, furze, brambles, or thorn shrubs, have become of considerable size, the general method of proceeding is to cut them down as close as possible to the surface of the ground, and afterwards to dig round, and grub up the roots in the manner that the larger trees are cleared. With furze it is sometimes customary to set fire to them, in order to uncover their stems before any attempt is made to grub them up; but this is a practice that ought to be as much as possible avoided, from the danger that may attend it, and the loss of the furze, as well as a large portion of the valuable vegetable matter accumulated in many cases beneath them.

As it has been found from experience, that such lands as have been attempted to be cleared from brushy plants of this kind, especially those of broom and furze, are extremely liable, from the roots and seeds that may be left in the soil, to have them coming up again in great abundance after they have been laid down to grass; it should be a practice to keep lands that are much disposed to their production in the state of tillage for such a length of time as may be fully sufficient, by the various means of cultivation, and the application and blending of lime and other suitable manures with them, to have them as completely removed as possible; and that when they are restored to the state of grass, to have them pastured, as much as can be conveniently done, with sheep.

Heathy lands should be cut as close to the surface of the ground as it can be conveniently done; and lime, in its caustic state, should be applied in large proportions.

When this sort of ground has been broken down and pulverised as much as possible by the operations of ploughing and harrowing, it should always, where not too stiff, be sown with some sort of close, luxuriant, green crop, such as turnips, peas, and tares, that may be fed off by sheep; but where it has a sour quality, and is more stiff, clayey, and adhesive, those plants that strike more deeply into the soil, as beans, rye, and oats of the grey kind. In many cases too, rape, peas, clover, and vetches, will succeed in a very beneficial manner. But as the principal intention in most cases of breaking up

this sort of land, is that of bringing it in a cheap and expeditious manner to a suitable condition after a grain crop or two for growing grass, the green crops, of whatever description they may be, should be consumed by animals upon the ground.

And in whatever method such lands may be brought into the state of cultivation, the processes of tillage should not be carried further than the destruction of the heathy or other coarse plants, and the removal of the sour and unfriendly disposition of such soils for the growth of useful vegetable productions. They should be then restored as soon as possible to the state of grass or pasture.

There is another description of land that is frequently to be brought into the state of tillage; this is that of the boggy kind. In these the first thing, after having them well drained by the cutting of proper ditches, which, where they are large, may serve for their inclosure, and by giving the ridges a suitable form in order to aid this, is to pare off and level the surface by means of the spade or plough; such matters as are of little value being deposited in the hollows, while those that are of a good quality may be mixed into a compost with good dung, where it can be procured, or with lime; together with the spare earth taken from the ditches, which should be immediately spread equally over the land, and incorporated as much as possible with it, by ploughing it up with a very slight or ebb furrow, in order that the uniting materials may not sink too deep for affording due support to the crop, that it may be cultivated. Indeed, though deep ploughing may sometimes be of utility in first opening up these soft soils, it should never be had recourse to when the application of manure is to be made; and on this account also the ploughings after the taking of different green crops should only be slight. It is seldom proper to continue soils of this description for any great length of time in the state of tillage, as from their great moisture, on account of the general flatness of their situation, and their being liable from continued ploughing to become very loose and open, so as not to afford proper nourishment and stability to the roots of the crops, this sort of land will in general be the most advantageous in the state of grass.

The most beneficial sorts of crops for these soils will in general be turnips, rape, or potatoes. The light and drier parts will be the most adapted to potatoes, as their bulbous roots will be there the most able to spread and extend themselves, and consequently produce large crops. These crops will, in the stiffer sorts of these soils, leave the land in a suitable condition for wheat or oats, and in the lighter for barley or rye.

Moss lands, from their being much disposed to the throwing up of grass, are not so proper for the growing of grain crops, but a crop or two may frequently be taken after potatoes or turnips, especially where liming has been performed some length of time. Oats and barley are mostly good crops, but such land is often too light for wheat. Where barley is employed, grass seeds are frequently sown with it, but it is probably a better practice to put them in separately. On those soils, rye-grass, as well as white and yellow clover, have been found to thrive extremely well, especially where they were in a proper state of preparation for them, as by the growth of potatoe or turnip crops. And though red clover has not always succeeded, it is probable, that in such mosses as are not of the deep kind, it will be found an useful plant. In some districts it has been found that clover may be sown with great advantage immediately after the potatoe crop, when it has been taken off early.

It is evident, from what has been advanced, that as there is much variety in soils of this kind, they will of course require different modes of tillage. Where they are very thin, and deposited upon a loamy or clayey substratum, it may be a good practice to plough so as to bring up a portion of them, by which, and the use of lime, the land may be rendered highly productive.

Ploughing. This, or some other method of loosening and turning up the superior parts of soils, is constantly requisite in order to render them suitable for the reception of the seed or crop that is to be cultivated. It is by means of this kind that a convenient bed for the roots of the young plants, and a proper condition of the land for supplying them with due nourishment, is in a great measure provided, as well as a proper state of dryness in many cases afforded.

There are certain circumstances that constantly demand notice in the practice of ploughing land. In all the stiff, heavy, and more adhesive kinds of soils, that are much disposed to the retention of moisture, whether they be perfectly clayey, or have more of a loamy quality, it should be a common rule never to plough or turn them up when wet in any great degree, except where the nature of the crop requires it. And further, great injury is produced by the treading of the team, as well as a much greater power necessary in performing the operation. But at the same time they should not be permitted to become so dry and hard as to afford too great resistance in that way, before the operation is proceeded upon.

But in the dry, sandy, and probably in some of the more mellow and friable kinds of loamy soils, the business of ploughing, especially for the putting in of the seed, may be performed when they are in a state of considerable moisture, not only without their suffering any inconvenience, or the seed being injured, but often with advantage, as they are liable to part with the watery particles that they contain too readily. On this last account the very dry sorts of sandy land should, whenever the weather is hot and dry, merely be stirred in such way as may be necessary to prevent the growth of weeds, otherwise the great exhalation of moisture in such seaseasons may render them too dry for the healthy vegetation of the seeds or plants that may be sown or set upon them.

In regard to the depth and frequency of ploughing lands, they must constantly depend, in a great measure, upon the qualities and the sorts of crops that are to be grown. But in general the different preparatory ploughings should be deeper than those of the seed furrow, which ought mostly to be light, and the slice not too much laid over, that the seed, especially where the broadcast method of sowing is adopted, may be the more perfectly covered.

Upon all light soils it is necessary to preserve, at six or eight inches below the surface, what farmers call a pan; that is, the staple, at that depth, should be kept unbroken; by which means manure will be kept longer

on the top: and in dry seasons the less depth the pan has, the less liable the corn will be to burn, provided the pan consists of earth, and not of rock; because the roots of the corn will find more moisture by striking against a body of close earth than they will in a greater depth of hollow earth; as it is evident the former preserves more moisture in dry seasons.

In regard to the frequency of ploughing or turning over ground, in order to prepare and render it suitable for the production of good crops, it is obvious there must be much difference according to the nature and condition of the soil, as well as the kind of crop that is to be grown. The stiff, clayey, loamy, and even chalky soils will, in general, stand in need of more frequent stirring, either by means of the plough, drag, or harrow, in order to separate and break down their tenacious particles, than those of the sandy or gravelly, and more light kinds, in which there is much less adhesion. Besides, where lands have been in a course of tillage for some time, whether they are of a clayey, loamy, or even sandy quality, they may require less frequent stirring than where the contrary is the case. And where the method of putting the seed into the ground by means of drill machines is to be had recourse to, a fine state of tilth will, in general, be indispensably necessary.

The nature of the crop that is to be cultivated must, however, in most cases, direct the number of ploughings that may be necessary, as some demand a much finer state of tillage than others; though in most cases a well-reduced earth is favourable.

In the choice of implements for the performance of this business, the agricultor should be careful that they are well suited to the nature and quality of the land, as it is not possible that any particular sort of plough can be employed with equal facility and advantage on soils of every description. The more stiff and heavy kinds of land will require ploughs of more strength than those of the thin chalky, and a light, sandy, or gravelly nature. The former may mostly be managed in a proper manner by any of the well-constructed kinds of strong ploughs; as the Somerset single-wheel plough, the Hampshire two-wheel plough, and the latter by those of the light sort, as the Rotheram plough, the Norfolk light two-wheeled plough, or the double-furrowed plough. See Plate LXX. Ploughs, &c. But whatever description of plough may be had resourse to, it is a matter of the greatest consequence that it be properly formed and attached to the draught, as where these points are not minutely attended to, there must constantly be a considerable loss in the economy of labour and time, as well as in the completeness of the work.

HUSK, the same with what botanists call the calyx, or cup of a flower. See CALYX.

HYACINTH, in natural history, a genus of pellucid gems, whose colour is red with an admixture of yellow. See ZIRCON.

HYACINTHUS, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronariæ. The corolla is campanulated, and there are three melliterous pores at the top of the germen. There are 17 species, of which the most remarkable is the orientalis, or eastern hyacinth. Of this there are a great number of varieties, amounting to some hundreds, each of which differs from the rest in some respect or other.

These plants are cultivated with the greatest success in Holland, whence great numbers are annually imported into Britain. Each variety is by the florists distinguished either by the name of the place where first raised, or the person who raised them, or the names of illustrious personages, as of kings, generals, poets, and celebrated ancient historians, gods, goddesses, &c. They are sold by all the seed-dealers. The prices are from 3*d.* per root to 5*l.* or 10*l.* or more; and some varieties are in such high esteem among the florists, that 20*l.* or 30*l.* will be given for a single bulb. They are hardy, and will prosper any where, though the fine kinds require a little shelter during the winter. They may be propagated either by seeds or off-sets from the roots.

HYADES, in astronomy, seven stars in the bull's head, famous among the poets for the bringing of rain. The principal of them is in the left eye, called by the Arabs Aldebaran.

HYALITE, in mineralogy, a stone frequently found in trap rocks. It occurs in grains, filaments, and rhomboidal masses. Texture foliate. Fracture uneven, inclining to conchoidal; sometimes opaque; specific gravity 2.11; colour pure white. Infusible 150° Wedgewood, but it yields to soda. According to Mr. Link it is composed of

57 silica
18 alumina
15 lime
——
90 and a little iron.

HYDATIDES, in medicine, little transparent vesicles or bladders, full of water, sometimes found solitary, and sometimes in clusters, upon the liver, and various other parts, especially in hydropical constitutions. See MEDICINE.

HYDNUM, a genus of the natural order of fungi, in the cryptogamia class of plants. The fungus is echinated or prickly on the under side. There are six species. One of them, named the imbricatum, is a native of Britain, and is found in the woods. It has a convex hat, tiled, standing on a smooth pillar, of a pale flesh-colour, with white prickles. It is eaten in Italy, and is said to be of a very delicate taste.

HYDRA, in astronomy, a southern constellation imagined to represent a water-serpent. The number of stars in this constellation in Ptolemy's catalogue is 25, and in the Britannic catalogue 68.

HYDRA, a genus of vermes zoophyta. The generic character is, animal fixing itself by the base, linear, gelatinous, naked, contractile, and furnished with setaceous tentacula, inhabiting fresh waters, and producing its deciduous offspring, or eggs, from the sides. The hydra viridis inhabits the stagnant waters and slowly running streams of Europe, generally on the surface of plants, and appears like a little transparent green jelly, when contracted and transparent: when expanded it is a linear body, fixed at one end, and surrounded at the other by tentacula, or arms placed in a circle round the mouth, and gradually producing its young from the sides, which at first seem small papillæ, increasing in length, till they assume the form of the parent, and then drop-

ping off. Like all its tribe, it has the power of reproducing parts which have been destroyed, and if cut or divided in any direction, each separate part becomes a perfect polype. See Adams on the Microscope. There are five species.

HYDRACHNA, a genus of insects of the order aptera: the generic character is, head, thorax, and abdomen united or connate; feelers two, jointed; eyes two, four, or six; legs eight, formed for swimming. The genus hydrachna, allied in the closest manner to that of acarus, under which the only species known to Linnæus were arranged, was first instituted by the ingenious Muller, by whose industrious researches many new and curious kinds have been discovered.

Among the larger insects of this genus is the hydrachna flaccida, so called, in order the more clearly to distinguish it from one or two others with which it may sometimes be confounded. Its size is that of a small pea, and its colour a very bright red: its shape is nearly globular, but the skin is of such a nature as to yield to every inclination of the body, so that the whole, when taken out of the water, has an irregularly flaccid appearance. This is most remarkable in the full-grown animal, which is also of a much more torpid nature than the rest of the genus, which are animals of great celerity of motion; and indeed the young or unadvanced individuals of the present species are of a more compact appearance, and swim with a greater degree of swiftness than the larger ones. The hydrachna flaccida is not very uncommon in stagnant waters.

Of all the hydrachnæ yet discovered by far the most elegant is the hydrachna geographica, so named from the fancied map-like distribution of its variegations. It is one of the largest of the genus, equalling the size of the former: it is occasionally seen in clear ponds and other stagnant waters, but is one of the rarer kinds: its shape is globular, and its colour a polished black, decorated with carmine-coloured spots and patches, which, in a certain light, are accompanied by a kind of gilded lustre.

Hydrachna roeseliana is named after Roesel, by whom it is figured in his well-known work on insects. It is of equal, or even superior size to that immediately preceding, which in many points it seems greatly to resemble; the ground-colour however in this is red, with black variegations, disposed in a different manner from those of the former. It is found, though not very frequently, in stagnant waters.

Among the smaller, or middle-sized hydrachnæ, one of the most common is the hydrachna extendens, which if of the size of a very small hemp-seed, and of a bright red colour, without any variegations; it is extremely nimble in its motions, and always carries the hinder pair of legs, which exceed the rest in length, in an extended posture.

Hydrachna araneoides is a small species, of a brown colour, clouded with red, and marked on the back by a very large oval patch of the same colour. It is found, like the rest, in stagnant waters, and has the habits of a young spider.

Some of the genus are distinguished by a kind of cylindric process at the end of the abdomen; of this kind is the hydrachna buccinator. It is a very small species, of a dark-brown colour, with a large rufous patch at the upper part of the body, the cylindric process being of a dull yellow. It is a native of stagnant waters.

The eggs of the hydrachnæ, which are small and round, are deposited in flat clusters, sometimes on the bodies of the napæ, and other water insects. The young, when first excluded, are furnished with six legs only, but after the first and second change of their skins, become eight legged insects.

HYDRARGYRUM, a name given in the pharmacopeia to mercury or quicksilver.

HYDRANGEA, a genus of the digynia order, in the decandria class of plants, and in the natural method ranking under the 13th order, succulentæ. The capsule is bilocular, birostrated, and cut round, or parting horizontally. There are three species, of which the hortensis is a very handsome and now a popular greenhouse plant.

HYDRASTIS, a genus of the polygamia order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. There is neither calyx nor nectarium; there are three petals, and the berry is composed of monospermous acini. There is one species, an herb of Canada.

HYDRAULICS. The science which has for its object the motion of fluids is called hydraulics; and its immediate application is to furnish us with the means of conducting water from one situation to another, by canals or aqueducts, and to elevate it by pumps, jets-d'eaux, and other hydraulic engines, either for the purpose of ornament or use.

In treating of this subject we shall commence with the simplest principles, and shall first speak of the discharge of fluids through small apertures.

When water flows from a vessel which has a hole or aperture in the bottom, small in comparison to the width of the vessel, the water descends vertically, and the surface appears smooth, but at three or four inches from the bottom the particles turn from this direction, and proceed on all sides with a motion more or less oblique towards the aperture. The same effect takes place when water flows through an aperture laterally. The tendency of the particles towards the aperture is a necessary consequence of their perfect mobility; for they will certainly be directed towards the point where there is the least resistance, and that point is the aperture.

It is also to be observed, that in this case, at a small distance from the bottom, a kind of funnel is formed in the water, the point of which corresponds to the centre of the aperture; when, however, the water flows through a lateral orifice or aperture, there is formed only a kind of half funnel, which does not appear to commence till the surface is near touching the upper side of the hole. It is probable that the funnel begins to form itself from the first moment of the flow; but it does not become perceptible till the surface is only at a small distance from the bottom.

It appears also, that the funnel commences higher or lower, according to the width of the bottom; and that the formation of it is less prompt or less perceptible, according to the proportion of the aperture to the extent of the bottom. The funnel is also augmented by any roughness which may exist at the sides or bottom of the vessel.

Water flows out of a small hole in the bottom of a vessel with a velocity equal to that which a ponderous

body acquires in falling from a height equal to the vertical height of the surface of the fluid above the aperture.

The same law takes place in a lateral orifice; for the pressure of the fluid is equal (at the same depth) in all directions, and consequently produces the same degree of velocity. See HYDROSTATICS.

A fluid, in running out of an aperture, acquires a velocity sufficient to make it remount to a vertical height equal to that of the fluid above the aperture, in the same manner as a falling body acquires a velocity capable of making it ascend to the height from which it descended.

It is evident, from the theory of falling bodies, that if the velocity of the fluid in running through the aperture was uniformly continued, the fluid would move through a space double the height of the fluid above the aperture, in the same time that a falling body would employ in descending from that height.

The height being the same, the velocity of the fluid in running out of the orifice will always be the same, whatever the species of the fluid may be, and whatever its density. It is true, that when the fluid has more density it presses more forcibly, but then the mass is more considerable; and it is evident, that when the moving powers are proportioned to the masses which they put in motion, the velocities are equal.

The quantities of a fluid discharged in the same space of time through different orifices, supposing the vessels equally full during the whole of the experiments, are to each other as the products of the areas of the apertures by the square roots of the heights. For instance, it has been proved by experiment, that a circular orifice of an inch diameter, made in a thin vessel or partition, and under a surface of fluid four feet in height, will furnish in one minute of time, 5436 cubic inches French.

If, therefore, it was an object to ascertain how much a circular orifice of two inches diameter, under nine feet of height from the surface of the water, would furnish in the same, the following proportion must be employed (it must be observed, that the orifice of two inches is four times as great as an orifice of one inch, because the areas of circles are as the squares of their diameters):

$$1 \times \sqrt{4} : 4 \times \sqrt{9} : : 5436 : x$$

Or at length

$$2 : 12 : : 5436 : 32616$$

$$\begin{array}{r} 12 \\ \hline 2)65232 \\ \hline \end{array}$$

Therefore 32616 cubic inches of water will flow from an aperture of two inches in diameter in one minute, the orifice being made nine inches from the surface, which is supposed to be kept at that height the whole time.

If a vessel of a prismatic form is filled with water, and permitted to empty itself entirely through an orifice at the bottom, and the time that it consumes in emptying itself is observed; and if afterwards, having replenished the vessel, the water is made to flow through the same aperture, the vessel being kept full the whole time, there will run out in this second instance, during the same time that the vessel took to empty itself at first, a quantity of water, double that which runs out in the first case, in which the abstraction of the water diminishes the height, and consequently the velocity.

We often perceive water flow through lateral apertures, which, though small in comparison to the width of the reservoirs, cannot be regarded as having all their points at an equal distance from the surface of the fluid; such, for example, as the apertures through which water sometimes flows in mills. The common method of determining the quantity discharged is as follows: suppose, in the first place, the aperture to be stopped up by a plate of metal, which is perforated with a number of holes; if each of these holes is regarded as particular and insulated, the rapidity of the flow through each will be according to the correspondent height of the fluid; then if the number of holes are multiplied ad infinitum, or which will amount to the same thing, if the plate is supposed to be entirely taken away, the velocity at each point of the supposed orifice will be according to the correspondent height of the fluid; and in estimating the quantity of water discharged, some attention must be paid to the inequality of the motion: yet it must not be asserted that this reasoning is entirely conclusive. In proportion as the sum of the small holes made in the plate is small in comparison with the size of the reservoir, the portions of water which flow through each hole are forced out by the absolute weight of the column above; but the moment that the number of apertures augment ad infinitum, and the streams of water which run through them become contiguous, it cannot be clearly said that the liquid flows in the same manner as through small insulated holes; yet as this hypothesis gives a result sufficiently conformable to experiments, it may be useful to preserve it, and the more so, as it leads to very simple calculations, and in all common questions this simplicity may be preferable to the minuteness of fractional operations.

The quantity of water which issues from these apertures in a given time is not so great as their size might at first suggest, because the stream is contracted by running out of each orifice, and that contraction extends to a distance nearly equal to half the diameter of the aperture; and the diameter of the contracted stream is to the diameter of the aperture a little more than as three to four, or as three and one-sixth to four, or nineteen to twenty-four; so that its area is to that of the aperture as ten to sixteen. It is nearly the same when water flows through lateral apertures. The contraction of the stream is a proof of what has been before stated, viz. that withinside a vessel the lateral particles direct themselves towards the orifice with a motion more or less oblique; and this oblique motion may be decomposed into two forces, the one parallel to the plane of the orifice, and which contracts the stream; the other perpendicular to the same plane, and the only one which produces the efflux.

This contraction occurs also when water is made to flow through pipes, and that at the entrance of the water into the pipe, and not at its exit, where the stream preserves a cylindrical form. We shall prove that this contraction diminishes, in a sensible manner, the quantity of water which would naturally flow.

In order to ascertain these facts by experiments, many have been made. In all the following instances, the ori-

fices through which the water flowed were pierced perpendicularly through plates of copper of about one-twenty-fourth of an inch thick, and the time of each experiment is reduced to one minute.

The constant height of the water above the centre of each orifice was 11 feet 8 inches 10 lines.

		No. of cubic inches furnished in 1 min.
Expt. 1.	Through an horizontal circular orifice of $\frac{1}{2}$ inch (6 lines) diameter -	2,311
2.	Through ditto of 1 inch diameter -	9,281
3.	Through ditto of 2 inches diameter	37,203
4.	Through an horizontal rectangular orifice of 1 inch long and $\frac{3}{12}$ inch wide - - - - - -	2,933
5.	Through an horizontal square orifice of 1 inch the side - -	11,817
6.	Through ditto of 2 inches each side of the orifice - - - -	47,361
Constant height = 9 feet.		
7.	Through a lateral circular orifice of $\frac{1}{2}$ inch diameter - - - -	2,018
8.	Through ditto of 1 inch diameter -	8,135
Constant height = 4 feet.		
9.	Through a lateral circular orifice of $\frac{1}{2}$ inch diameter - - - -	1,353
10.	Through ditto of 1 inch diameter -	5,436
Constant height = $\frac{7}{12}$ inch.		
11.	Through a lateral circular orifice of 1 inch diameter - - - -	628

It follows from the preceding table,

1. That the quantities of water discharged in the same time, by different apertures, under the same height of surface in the reservoir, are to each other nearly as the areas of the apertures. Compare together the results of the second and third experiments of which the areas of the orifices are in the proportion of one to four, and it will be found that the quantities of water afforded, viz. 9281 cubic inches, 37203, inches, are very nearly in the same proportion.

2. That the quantities of water discharged in the same time through the same aperture, under different heights of surface in the reservoirs, are to each other nearly as the square roots of the corresponding heights of the water in the reservoir above the centre of the aperture. Compare together the results of the 8th and 10th experiments, where the heights of the reservoirs are nine and four feet, the square roots of which are three and two, and it will be found that the two quantities of water, 8135 cubic inches, 5436 cubic inches, which run through the same orifice of one inch diameter under the different heights of nine feet and four feet, are to each other nearly in the proportion of three to two.

3. That in general the quantities of water discharged in the same time through different apertures, under different heights of surface in the reservoirs, are to each other as the areas of the apertures are to the square roots of the heights of water in the reservoirs.

4. That in consequence of the friction, the small apertures furnish a less quantity of water in proportion than the great ones, under the same height of water in the reservoir; because, comparatively to the extent of the area in each orifice, there are more points of friction against the sides of the orifice in the small than there are in the great ones; for the circumferences do not diminish so much as the areas.

5. That of many apertures of equal areas, that of which the circumference is the least, will, on account of the friction, furnish more water than the others, under the same height of the reservoir; circular apertures are, for this reason, the most advantageous of all; for the circumference of a circle is the shortest line that can be made use of to inclose a given space, therefore there is less surface of friction relatively to the size of the area.

It is easy to perceive, that the quantity of water discharged in the table of experiments is not near so great as might be expected from the extent of the areas and the heights of the reservoirs. The quantity is in fact diminished by the friction, and still more by the contraction of the stream; for the velocity which is in proportion to the entire altitude of the fluid is not sensibly changed. Supposing, first, that the area of the stream is the same as that of the orifice; and supposing, secondly, that the stream is contracted, then the difference of the quantities afforded is as sixteen to ten; that is, supposing the area of the aperture to be diminished in the proportion of sixteen to ten, the discharge of the fluid out of vessels kept equally full may be determined with sufficient exactness. By the expression, an inch of water, is understood the quantity which flows out of a circular and lateral orifice of one inch diameter, the surface of the water being constantly kept seven-twelfths of an inch above the orifice. This is the case with the eleventh experiment in the preceding table, where it appears that the quantity of water furnished is 628 cubic inches. Mr. Mariotte, who made the same experiment, found the quantity to be a little more; but it is probable that he might commit a small error, because the experiment just cited was made, M. Brisson informs us, with the utmost care and attention. A (French) pint of water, he adds, instead of weighing two pounds, as is commonly believed, is proved to fall short of that weight considerably, as will be evident by strictly examining that experiment.

When additional pipes are employed, it appears,

First, That the quantity of water discharged by different additional pipes, under the same height of water in the reservoir, is proportional to the areas of the apertures, or to the squares of their diameters.

Secondly, That the quantities of water discharged through additional pipes of the same diameter, under different altitudes of water in the reservoir, are proportional to the square root of the altitude.

Thirdly, That in general the quantities of water discharged in the same space of time through different additional pipes, under different heights of water in the reservoir, are to each other nearly as the product of the square of the diameters of the pipes by the square root of the altitude of the reservoirs.

The efflux of water, therefore, through additional pipes, follows the same laws as water when discharged through apertures made in thin substances.

If the vessel AB (Plate LXXI. Hydrostatics, &c. fig. 1.) is full of water, and the horizontal pipe D in the middle of its side, and the semicircle NEC described upon D, as a centre, with the radius, or semidiameter DC, or

DN, the perpendicular DE to the diameter CDN, is the longest that can be drawn from any part of the diameter to the circumference: and if the vessel be kept full, the jet will spout from the pipe D to the horizontal distance MN, which is double the length of the perpendicular DE. If two other pipes, as F and G, be fixed into the side of the vessel, at equal distances above and below the pipe D, the perpendiculars FH and GI, from these pipes to the semicircle will be equal; and the jets spouting from them, will each go to the horizontal distance NK, which is double the length of either of the perpendiculars FH or GI.

Fluids, by their pressure, may be conveyed over hills and valleys, in bended pipes, to any height not greater than the level of the springs whence they flow. This the ancients were ignorant of; and therefore they usually built aqueducts (vast rows of arches, one above another, between two hills, at an immense expense of money, time, and labour) in order to convey water over them, across the valley.

This is now done to equal advantage, and at much less expense, by a range of pipes laid down one hill and up the other. If water is poured into one of the legs of the bended pipe ACB (fig. 2.) it will rise exactly to the same level in the other. The reason is obvious: in the leg A there are, suppose, two ounces of water, endeavouring by the force of gravity to descend with the force of two; this will thurst forward, buoy up and support an equal quantity of a like fluid in B; and the bottom of the machine C, against which both sides equally bear, will of consequence sustain a double pressure, or that of four ounces; and in the present case, will pretty well represent the prop, or fixed point, of a balance-beam; as the equal fluid columns AC and BC, may be admitted to denote equal weights, suspended on the balance-arms, counterpoising each other: so that the rise of fluids to their first level, thus considered, is a case truly statical; and all their other motions proceed only from weight added.

We have seen, that water will rise through bended pipes to the same level as the reservoir from which it proceeds. Upon the same principle, jets, or fountains, are formed; for if near the bottom of the vessel AB (fig. 1.) you fasten a small pipe *m*, bending upwards, the water will spout out through the pipe, and rise nearly as high as the surface of the water in the vessel. It will not rise quite so high, because it is somewhat impeded by the resistance of the air, and the friction against the opening of the pipe, or adjutage.

It is always found necessary to increase the bore of the adjutage, or spouting pipe, with the height of the reservoir; for if it is too small, the rising stream will want sufficient weight and power to divide the air, which being densest near the earth, a small stream of water, endeavouring to mount to a great height, will be dashed against it with so much violence, as to fall away in a mist, and be wholly lost.

There is a certain and fit proportion to be observed between the adjutage by which the jet is delivered, and the pipe conducting it from the head. In general, about five times the diameter of the adjutage, for jets under half an inch, and six or seven times for all above, will give the size of pipes of conduct pretty well; though it will always be an error on the right side, to have them rather larger than in strictness they ought to be, that the jet may always be freely supplied with water, and in due time.

For a like reason, if there is occasion for a cock to be placed in any part of the pipe of conduct, particular care must be taken that it should be there bigger in proportion, that the water may not be pinched, but that the cavity be left at least equal to the bore of the rest of the pipe.

The bore of an adjutage cannot be too smooth, or true. Those that are cylindrical are best; those that are bored conical, worst; because of the reflections of the water from the inclined sides of the machine, which, in the hurry of the issuing stream, will in them unavoidably be made.

Archimedes' screw (fig. 7.) deserves consideration, not only for its antiquity, but its usefulness in raising water. It consists of a long cylinder, with a hollow pipe-tube, or groove, coiled about it, as represented in the figure. It is placed in a position oblique to the horizon, with the lower end in the water, the other being supported on the lower part of the winch I, by which the screw and cylinder are turned round. As soon as the screw is immersed in water, it immediately rises in the machine by the orifice C, to the level of the surface of the water E; and if the point of the helix, or spiral, which in the beginning of the motion is coincident with the surface of the water, happens not to be on the lower side of the cylinder, the water will, upon the motion of the screw, move on in the helix, until it comes to the point which is on the under side, and coincident with the watery surface: when it is arrived at that point, it cannot afterwards possess any other part of the spiral, than that which is upon the lowest part of the cylinder, for it cannot move towards H, because H is situated higher; and since this will ever be the case, after the surface of the water in the helix has attained the point E; it is plain that it must always be on the under side of the cylinder. But since the cylinder is in motion, every part of the spiral screw from EF, will by degrees succeed to the under part of the cylinder; the water therefore in the helix must succeed to every part from E to F, as it comes to the lower side; that is, it must ascend on the lower part of the cylinder through all the length of the pipe, until it comes to the orifice at top, where it will run out.

Of all the machines the ancients invented to raise water, it appears that though Archimedes' screw was the most curious, the tympanum, mentioned by Vitruvius, elevated the greatest quantity at once; a brief discription of this may suffice, as preparatory to the account of machines made in imitation of it, but more ingenious and more perfect.

The tympanum is a great hollow wheel, forming a kind of barrel or drum (as its name imports) composed of several planks joined together, well calked and pitched, and having a horizontal axle on which it turns: the interior of this drum is divided into eight equal spaces by as many partitions placed in the directions of the radii; each space or cell has an orifice of about half a foot in the rim of the drum or wheel, so shaped as to facilitate the admission of the water; moreover, there are eight hollow channels running contiguous to each other, and parallel

to the axle of the wheel, each corresponding to one of the eight large cells; into these channels the water passes out of the cells just mentioned, and after running along the channels to a convenient distance, it escapes through orifices into a reservoir placed just under the axle. Thus the water is elevated through a vertical space equal to the radius of the hollow wheel. When the tympanum is used to raise water from a running stream, it is moved by means of float boards which are impelled by the stream; but when it it employed to raise stagnant water; there is commonly a smaller wheel on the same shaft, which is turned by men walking in it, as in the old walking crane. The chief defect of this machine is that it raises the water in the most disadvantageous situation possible, for the load being found always towards the extremity of a radius of the wheel, the arm of the effective lever which answers to its increase through the whole quadrant the water describes in passing from the bottom of the wheel to the altitude of its centre; so that the power must act as if it was applied at a winch handle, and cannot therefore act uniformly.

Mr. H. Sarjeant, of Whitehaven, contrived a very cheap engine for raising water, for which the Society for the Encouragement of Arts awarded him a silver medal in the year 1801. A sketch of this simple invention is given in fig. 8.

This engine was erected at Irton-hall, which is situated on an ascent of 60 or 61 feet perpendicular height: at the foot of this elevation, about 140 yards distant from the offices, there runs a small stream of water, and in order to procure a constant supply of that necessary fluid, the object was to raise such stream to the house for culinary and domestic uses. With this view, a dam was formed at a short distance above the current, so as to cause a fall of about four feet: the water was then conducted through a wooden trough, into which a piece of leaden pipe, two inches in diameter, was inserted, and part of which is delineated at A.

The stream of this pipe is directed in such a manner as to run into the bucket B, when the latter is elevated; but as soon as it begins to descend, the stream passes over it, and flows progressively to supply the wooden trough or well, at the foot of which stands the forcing-pump C, being three inches in diameter.

D is an iron cylinder attached to the pump-rod, which passes through it: such cylinder is filled with lead, and weighs about 240 lbs. This power works the pump, and forces the water to ascend to the house through a pipe one inch in diameter, and which is 420 feet in length.

At E is fixed a cord, which, when the bucket approaches to within four or five inches of its lowest projection, extends, and opens a valve in the bottom of the vessel through which the water is discharged.

An engine in a great degree similar to this was erected some years ago by the late James Spedding, esq. for a lead mine near Keswick, with the addition of a smaller bucket which emptied itself into the larger near the beginning of its descent, without which addition it was found that the beam only acquired a libratory motion, without making a full and effective stroke.

To answer this purpose in a more simple way, Mr. Sarjeant constructed the small engine in such manner as to finish its stroke (speaking of the bucket end) when the beam comes into an horizontal position, or a little below it. By this means the lever is virtually lengthened in its descent in the proportion of the radius to the cosine, of about 30 degrees, or as seven to six nearly, and consequently its power is increased in an equal proportion.

It is evident, that the opening of the valve might have been effected, perhaps better, by a projecting pin at the bottom, but Mr. S. chose to give an exact description of the engine as it stands. It has now been some years in use, and completely answers the purpose intended.

The only artificers employed, except the plumber, were a country blacksmith and carpenter; and the whole cost, exclusive of the pump and pipes, did not amount to 5*l*. Pumps are engines depending also on the principles of hydraulics. See PUMP.

HYDRO-CARBONATES, combinations of carbon with hydrogen. A gas of this name is obtained from moistened charcoal by distillation.

HYDROCELE. See SURGERY.

HYDROCHARIS, the *little water-lily*, a genus of the enneandria order, in the diœcia class of plants, and in the natural method ranking under the first order, palmæ. The spatha of the male is diphyllous; the calyx trifid; the corolla tripetalous; the styles six; the capsule has six cells, and is polyspermous inferior. There is only one species, a native of Britain, growing in slow streams and wet ditches. It has kidney-shaped leaves, thick, smooth, and of a brownish-green colour, with white blossoms. There is a variety with double flowers, of a very sweet smell.

HYDROCOTYLE, *water-naval wort*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The umbel is simple; the involucrum tetraphyllous; the petal entire; the seeds are half round and compressed. There are 15 species, none of which are ever cultivated in gardens. One of them, a native of Britain, growing in marshy grounds, is supposed by the farmers to occasion the rot in sheep. The leaves have central leaf-stalks, with about five flowers in a rundle; the petals are of a reddish white.

HYDROGEN, in chemistry, one of the simple combustibles, the base of hydrogen gas, formerly called inflammable air.

HYDROGEN-GAS. To obtain this, put one part of iron-filings into a retort, attached to the pneumatic cistern, and pour thereon two parts of sulphuric acid previously diluted with four times its bulk of water. Immediately the mixture begins to boil or effervesce with violence, and air-bubbles rush abundantly from the beak of the retort. Allow them to escape for a little, till you suppose that the common air which previously filled the retort has been displaced by the newly generated air. Then place an inverted jar over the beak of the retort. The bubbles rush in abundantly and soon fill the jar.

It was obtained by Dr. Mayow and by Dr. Hales from various substances, and has been known long before in mines under the name of the fire-damp. But Mr. Cavendish ought to be considered as its real discoverer; since it was he who first examined it, and pointed out the

difference between it and atmospheric air, and who ascertained the greatest number of its properties.

Hydrogen gas, like air, is invisable and elastic; and capable of indefinite compression and dilatation. Its specific gravity differs according to its purity. Kirwan found it 0.00010; Lavoisier 0.000094, or about 12 times lighter than common air. All burning substances are immediately extinguished by being plunged into the gas. It is incapable therefore of supporting combustion. Small animals, when they are obliged to breathe it, die; but large animals resist its action longer. Scheele found that he could breathe it for some time without much inconvenience; but Fontana, who repeated the experiment, affirmed that this was owing to the quantity of common air contained in the lungs when he began to breathe; for on expiring as strongly as possible before drawing in the hydrogen gas, he could only make three respirations, and even these three produced extreme feebleness and oppression about the breast.

The ingenious Mr. Davy, professor of chemistry in the Royal institution, to whom we are indebted for many curious and important, but rather hazardous experiments on respiration, made chiefly upon himself, after a complete exhaustion of his lungs, found great difficulty in breathing this gas for so long as half a minute. It produced uneasy feelings in the chest, momentary loss of muscular power, and sometimes a transient giddiness.

Pilatre de Rozier publicly verified the assertions of Scheele. He breathed hydrogen gas six or seven times from a bladder without inconvenience. To demonstrate that it was really hydrogen gas which he was breathing, he made a strong inspiration, and expired the air, slowly through a long tube. On bringing a lighted taper to the end of the tube, the gas took fire, and continued to burn for some time. It was objected to him, that the gas which he breathed was diluted with common air. To show that this was not the case, he mixed together one part of common air and nine parts of hydrogen gas, and having drawn the mixture into his lungs, he threw it out the same way. On applying a taper to the tube, the whole of the gas exploded in his mouth, and almost stunned him. At first he thought that the whole of his teeth had been driven out, but fortunately he received no injury whatever.

If a phial is filled with hydrogen gas, and a lighted candle brought to its mouth, the gas will take fire, and burn gradually till it is all consumed. If the hydrogen gas is pure, the flame is of a white colour; but if the gas holds any substance in solution, which is often the case, the flame is tinged of different colours, according to the substance. It is most usually reddish, because the gas holds in solution a little charcoal. A redhot iron likewise sets fire to hydrogen gas. From my experiments it follows, that the temperature at which the gas takes fire is about 1000°.

If pure oxygen and hydrogen gas be mixed together, they remain unaltered; but if a lighted taper be brought into contact with them, or an electric spark be made to pass through them, they burn with astonishing rapidity, and produce a violent explosion. If these two gasses be mixed in the proportion of one part in bulk of oxygen gas and 2.527 parts of hydrogen gas, or more accurately 85 parts by weight of oxygen gas and 15 of hydrogen gas, they explode over water without leaving any visible residuum; the vessel in which they were contained (provided the gasses were pure) being completely filled with water. But if the explosion be made in a close vessel, there is always found instead of them a quantity of water exactly equal to them in weight. This water must be composed of these two gasses; for it did not previously exist in the vessel, and no other substance besides the gasses were introduced. Water then is composed of oxygen and hydrogen; and the combustion of hydrogen is nothing else but the act of its combination with oxygen.

When two parts (in bulk) of hydrogen gas are mixed with six parts of common air, the mixture explodes with equal violence; and after the explosion the bulk of the mixture is reduced to five parts. The whole of the hydrogen gas is consumed, and likewise all that part of the common air which consists of oxygen gas, and there is formed a quantity of water equal in weight to these two bodies. This experiment is often employed to ascertain the purity of hydrogen gas. Common air and the hydrogen gas to be examined are mixed in certain proportions in a glass tube, graduated and closed at one end; they are then fired by an electric spark. The purity of the gas is proportional to the diminution of bulk. Thus, when the bulk of a mixture of two parts of the hydrogen gas and six parts of air is diminished after the explosion to five parts, the hydrogen gas may be considered as pure; if only to six, it contains some foreign ingredients, and so on. This method of detecting the purity of hydrogen gas was first employed by Berthollet. Volta, indeed, had employed it before him; but for a different purpose.

Hydrogen gas is not sensibly absorbed by water, though left for some time in contact with it. But by artificial pressure water may be made to absorb about the third part of its bulk of that gas. The taste of the water is not sensibly altered. Mr. Paul, who first formed this compound, inform us, that it is useful in inflammatory fevers and in nervous complants, but it is injurious in dropsy.

Hydrogen gas dissolves sulphur, phosphorus, and carbon. The compounds are called sulphureted, phosphureted, and carbureted hydrogen gas. See Air, Chemistry, &c.

HYDROGENIZED *sulphurets*, certain bases combined with sulphureted hydrogen.

HYDROGRAPHY, the art of measuring and describing the sea, rivers, lakes, and canals.

With regard to the sea, it gives an account of the tides, counter-tides, soundings, bays, gulphs, creeks, &c. as also of the rocks, shelves, sands, shallows, promontories, harbours, the distance and bearing of one port from another, with every thing that is remarkable, whether out at sea or on the coast.

HYDROLEA, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is pentaphyllous; the corolla rotaceous; the filaments at the base are cordate; the capsule is bilocular and bivalved. There are four species, herbs of the East and West Indies.

HYDROMETER, an instrument much used for determining the specific gravities of liquids. It usually consists of a hollow sphere of glass or metal B, and ba-

lanced by another *b* below, containing quicksilver, or a metallic weight. Plate LXXI. fig. 19. The larger ball has a shorter neck at C. into which is screwed the graduated stem AC, which by a small weight at A causes the instrument to descend in the fluid with part of the stem. When this instrument is swimming in the jar ILMK, the part of the fluid displaced by it will be equal in bulk to the part of the instrument under water, and equal in weight to the whole instrument. This instrument, therefore, marks the differences in the density of fluids by the place at which the surface cuts the stem as it floats, or by the proportionate addition or diminution of weight which is required to make it float at the same level in each.

Beaume's areometer is often referred to in the works of French chemists. The inventor seems to have been led to a method of making instruments of this kind, which should agree with each other by reflecting on the way in which thermometers are graduated, that is, by means of an interval between two stationary points of temperature. Thus M. Beaume' adopted two determinate densities, in order to mark an interval in the stem of his hydrometer. These were that of pure water, and that of water containing $\frac{15}{85}$ parts of its weight of pure common salt at 10° Reaumur or 57° Fahrenheit. The instrument (represented by fig. 20.) was so balanced as to sink in the water to 0 near the top of the stem. In the saline solution the latter emerged more, and a certain additional portion appeared above, which was assumed to contain 15 degrees. By means of a scale and compasses, a scale of equal degrees was thus formed, adapted to the length of the stem, and being fixed within it, at a proper height, the latter was sealed at the blow-pipe without altering the weight. It is usually constructed in two pieces, to avoid an inconvenient length; one of which serves for the lower, the other for the higher, degrees of density. The glasses may be procured from the makers of thermometers, and it is convenient to have a passage from the top quite down to the lower bulb for introducing the quicksilver, which being adjusted, may be secured there by a small morsel of cork. It is obvious that persons of ingenuity may adapt such instruments to their own purposes, by fixing on two liquids of known specific gravities to serve as the extremes of their scale, and may thus apply them to the trial of all liquids, from ether to sulphuric acid, in respect to gross differences, or for the purpose of having them of uniform strength. But the instrument is not to be depended on for those accurate reports on the specific gravity of liquids which are expected in detailing chemical experiments.

Fahrenheit contrived a more accurate metallic hydrometer, having a very slender stem, terminating in a small dish. The middle, or half-length of the stem, is distinguished by a fine line across. In this instrument every division of the stem is rejected, and it is always immersed to the line by means of weights put into the dish. Thus, as the part immersed is constantly of the same magnitude, and the whole weight of the hydrometer is known; this last weight, added to the weight in the dish, will be equal to that of the fluid, displaced by the instrument. Consequently, as the whole weight of the hydrometer and its load, when adjusted in distilled water, is to 1.000, so is the whole weight when adjusted in any other fluid, to the number expressing the specific gravity of that fluid.

Were the instrument constructed so that it should displace exactly 1.000 grains of distilled water at a mean temperature, the grains to be added or taken away for any other fluid would express the difference of the specific gravity at once. But as this would require much nicety, the weight of the instrument and its load adjusted in distilled water may be ascertained, and a set of decimal weights provided, each of which should bear the same proportion to its nominal value in grains that the whole adjusted in distilled water did to 1.000. By this, or by the former expedient, the trouble of calculation may be avoided; but those who use the instrument often will find it expedient to construct a set of tables adapted to the same purpose. See SPIRITS.

HYDRO-OXIDES, metallic oxides combined with water.

HYDROPHOBIA. See MEDICINE.

HYDROPHILUS, a genus of insects of the coleoptera order. The generic character is, antennæ clavate-perfoliate; hind legs villose, formed for swimming. The principal European species of this genus, which is not an uncommon insect in our country, is the hydrophilus piceus, perhaps the largest of the British coleoptera, if we except the lucanus cervus; measuring nearly an inch and half in length. It is entirely black, and of a smooth surface, and is particularly distinguished by the form of its thorax, which is produced beneath into a very long and sharp-pointed spine, stretching to a considerable distance down the abdomen; the hind legs are furnished on each side with strong, but very fine, hairs. It is a native of stagnant waters, where its larva is principally observed to prey on the smaller kind of water snails, and is distinguished by a particularity in the highest degree remarkable; this consists in the apparently anomalous situation of the legs, which seem, unless very accurately considered, to be placed, not beneath the thorax, as in other insects, but on the upper part, and thence to be deflected towards the sides. This uncommon appearance, however, is not owing to a real dorsal insertion of the legs, but principally to the peculiar shape and position of the head; and the deception is so much heightened by the inverted posture in which the insect generally swims and rests, that it is by no means easy, even for the most scientific observer, to divest himself of the erroneous idea before mentioned.

The larvæ of the hydrophilus are supposed to remain about two years before they change into pupæ or chrysalides. When the larva is arrived at its full growth, it secretes itself in the bank of the water it inhabits, and having formed a convenient cavity or cell, lies dormant for some time, after which it divests itself of its skin, and appears in the form of a chrysalis, in which state having continued for some time longer, it again delivers itself from its exuviæ, and appears in its complete or beetle form. When first disengaged from the skin of the chrysalis, it is of a pale colour, and very tender; but in the space of a few hours the elytra, or wing-cases, acquire a degree of strength and colour, which gradually grows more and more intense, till the animal, finding itself sufficiently strong, comes forth from its retreat, and commits itself in its new form to the waters.

The male is distinguished from the female by the structure of the fore legs, which are furnished, near the setting on of the feet, with a sort of horny, concave flap or shield; the legs of the females being destitute of this part.

The female of the hydrophilus piceus affords an example of a faculty which seems to be exercised by no other coleopterous insect, viz. that of spinning a kind of web or flattish circular case of silk, which it leaves floating on the water, and in which it deposits its eggs. This case is terminated on its upper surface by a lengthened conical process resembling a horn, of a brown colour, and of a much stronger or denser nature than the case itself, which is white. The young larvæ, as soon as hatched, make their escape from the envelopement of the case, and commit themselves to the water.

The hydrophilus caraboides is a species measuring about three quarters of an inch in length, and is of a polished black colour, and of an oval shape.

The genus hydrophilus has been greatly increased by the persevering researches of modern entomologists. Mr. Marsham enumerates 28 British species.

HYDROPHYLLAX, a genus of the monogynia order, in the tetrandria class of plants. The calyx is tetrapartite; the corolla funnel-shaped; the fruit two-edged and one-seeded. There is one species, an aquatic of the East Indies.

HYDROPHYLLUM, *water-leaf*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is campanulated, with five melliferous longitudinal stria on the inside; the stigma is bifid; the capsule globose and bivalved. There are two species; the virginianum, or water-leaf of Mormus, grows naturally in Canada and many other parts of America on moist ground. The root is composed of many strong fleshy fibres, from which arise many leaves with footstalks five or six inches long, jagged into three, five, or seven lobes, almost to the mid-rib, indented on their edges. The flowers are produced in loose clusters hanging downward, are bell-shaped, and of a dirty white colour.

HYDROSCOPE, an instrument anciently used for the measuring of time. The hydroscope was a kind of water-clock, consisting of a cylindrical tube, conical at bottom: the cylinder was graduated, or marked out with divisions, to which the top of the water becoming successively contiguous, as it trickled out, the vertex of the cone pointed out the hour.

HYDROSTATICAL BALANCE, a kind of balance contrived for the easy and exact finding the specific gravities of bodies, both liquid and solid. See HYDROSTATICS.

HYDROSTATICS have for their object the weight and pressure of fluids; and in this branch of science the art of determining the specific gravities of bodies is usually included, but this we have already been under a necessity of anticipating. Archimedes, among the ancients, accomplished the most remarkable discoveries in this science. He is honoured even at this day, as the inventor of the ingenious hydrostatic process, by which the purity or baseness of a crown of gold was ascertained. Among the moderns we are indebted to Gallileo, Torricelli, Descartes, Pascal, Guglielmini, and Mariotte, for the best information on this subject; and by their experiments (which are as curious as they are decisive) we are instructed in what we may expect or fear from the power of fluids violently acted upon by the principle of gravity, and in what manner and upon what principles we may employ, for the use of man, the hydraulic machines.

It has been observed in another place (See GRAVITATION), that the propensity which bodies have of approaching towards the earth, or perhaps towards its centre, is the only cause of what we term weight or gravity, and that it is by the continual efforts which they make to obey that law, that they press upon every obstacle which impedes their progress. As fluids, like solid bodies, are impelled by their gravity, so in this case they press upon every object which opposes their fall; but from their nature they press in a different manner from solid bodies, hence arise the peculiar phenomena concerning which we are now to inquire.

Fluids are substances, the component parts of which are moveable among themselves, having scarcely any cohesion one with another, and moving independently of each other. Some philosophers have included in this definition what they term the grosser fluids, as, for example, a heap of corn, a heap of shot, of sand, &c. as well as the rarer and more elastic fluids, as common air, and all other aeriform substances. The proper objects, however, of the hydrostatic science, are those fluids which, in common language, are termed liquids, or those which always present to us a plane surface, level or parallel to the horizon.

All liquid substances are not equally so; hence it follows, that the laws of hydrostatics apply with less exactness in proportion as those substances depart from perfect fluidity. Water and oil both flow when the vessels, which contain them, are either overturned or broken; but the effusion of oil is slower than that of water, because the particles of oil have more cohesion among themselves. The most singular effects in hydrostatics principally depend, perhaps, upon the extreme minuteness of the particles of fluids, but at least upon their great mobility.

To preserve a lucid order in the consideration of this subject, it will be necessary to divide the objects of our inquiry into three branches. In the first place, therefore, we shall consider in what manner the principle of gravity acts on the particles of fluids, and the phenomena which it produces in the fluids themselves; as well as their action against the sides, the bottoms, and tops of the vessels in which they are contained. Secondly, in what manner fluids of different densities act upon each other; and thirdly, the action of fluids on bodies immersed in them.

I. In pursuing the first object of this inquiry, it may be established as an axiom:

1. That the parts of the same fluid act with respect to their weight or pressure, independently of each other.

This property arises from their having scarcely any cohesion among themselves. It is otherwise with solid bodies; their several parts adhering together they press in one common mass; hence the falling of solid bodies is productive of a different effect from that of liquids. We dread the falling of a pound of ice upon our heads, while we are much more indifferent concerning that of a pound of water. The latter, in its descent, is divided by the

resistance of the air, by which some of its parts are retarded more than others; and the swiftness of the whole mass is still more retarded by this division than it otherwise would be; for by being thus divided it requires a larger surface, which abates its effect. On the contrary, a solid body falls upon a small space, which receives its whole force. Hence it follows, that angular bodies falling upon any part of the human frame are more dangerous than flat or plane ones of the same weight, and descending from the same height.

It follows from this principle, that if an aperture is made at the bottom of a vessel full of any fluid, in order to prevent the flowing out of the liquor, it is only necessary to counteract the weight of that column of fluid which has the aperture for its base, and that to counteract that weight it is the same whether the vessel is full of liquor, or whether it contains only a column, the base of which shall be equal to the aperture at the bottom.

Let the cylindrical vessel of glass A B (Plate LXXI. Hodrostatics, fig. 9.) have a hole in the bottom at C, furnished with a cylindrical ferule of copper of an inch diameter D, which is to be stopped with a piston G, or the sucker of a pump well fitted to the ferule, and oiled, that it may yield to a moderate pressure. Let the piston be supported by a small rod G H, fastened at H to the silk which unites with the portion of the pulley, M, with which the extremity of the lever M N is furnished, and which has for its center of motion the point L. The other portion of the pulley N, which terminates the other extremity of the lever, is also furnished with lines of silk, which support the small bason or scale I. Upon the copper ferule D then fit a cylindrical tube of glass F E, the interior diameter of which is equal to that of the ferule, and its height equal to that of the vessel A B. When the apparatus is disposed in this manner, fill the tube E F with water, and continue to put small weights into the scale I, until the piston begins to rise. Afterwards take away the glass tube E F, and place the piston G in the copper ferule D, and pour water into the large vessel A B, and it will appear that the same weights as before in the bason I, will raise up the piston when the larger vessel A B is entirely full. Hence it follows that there is the same power to be counteracted, whether there rests upon the piston only a column of water of its own size, or whether the vessel A B is entirely full. Such a column, therefore, presses upon its base independently of the rest of the water contained in the vessel.

To account for this, let us suppose all the water in a vessel to be divided into several columns, 1, 2, 3, 4, 5, (fig. 10.) each composed of an equal number of parts. If the bottom of the vessel, which serves for the base and support of all the columns, is opened in *a*, the column 3, being no longer supported, will descend through the aperture, sliding between the two columns 2 and 4, which are supported by the parts of the bottom of the vessel *b* and *c*, all the moveable parts of which become (if we may use the expression) small rollers, which retard the fall only in a very slight degree. This effect is the result of the small degree of cohesion between the parts of the fluid. If the columns 1 and 2 on the one part, and 4 and 5 on the other, were composed of parts adhering together, they would retard each other in their descent during their whole length, in the same manner as a wax candle would do; and by the fall of the column 3, a void would be made between them. But as all the particles are extremely minute, moving easily upon each other, they descend when the summit of the column 3 begins to descend, having no longer any support from that side; and the superficies of the whole mass descends in the same manner, though only one of the columns caused the flow from its fall. When the parts have a degree of viscosity, as those of oily fluids, or when the mass of the flowing liquor has much more of breadth than of height, the void which the descending column leaves above it is easily perceived, for then the surface, instead of being plane and even, is hollow in the middle, and assumes a funnel-like form, because the adjacent parts do not arrive with sufficient swiftness to replace those which descend through the aperture; besides the pressure of the air above, the aperture is stronger than its resistance below.

From what has been now stated, it is easy to perceive how fluids differ from solids in the phenomena of gravitation. If the vessel A B (fig. 9.) being full of water, and the tube E F being removed, it was required to raise up the piston G; all that is necessary in this case is, to support the weight of the column of water directly above the piston, because this column can move independently of the remainder; but if the whole mass of water was converted into ice, then the mass ceasing to be a liquid, and all its parts adhering together, to raise up the piston it would be necessary to support the weight of the whole mass.

2. Fluids press equally in all directions.

In other words, they not only press from the top to the bottom like other bodies, but they also press, according to their weight, upon all bodies that oppose them in a lateral direction, and even from the bottom to the top. Hence, if a cask is filled with liquid oil, the oil will run out if an aperture is made in the side, but when it is congealed it will not run out on account of its having become a solid body, for solid bodies press only from their vertex to their base, and not laterally.

To understand properly this lateral pressure of fluids, and also that which they exert from their base towards their vertex, it is necessary to consider them as a mass of small globules deposited in a vessel, and to remember that these minute globules are not arranged regularly as upon a cord, but that very frequently one column exercises its pressure between two others, and has a propensity to displace them, as may be seen in fig. 11. where the perpendicular pressure which is made opposite to the point *d*, is directed by the lateral columns towards the sides, *e*, *f*, of the vessel, in such a manner, that if the vessel was open in those places the liquid would flow out, on account of the great mobility of its parts. It is by the same mode of reasoning, that the pressure of fluids, from their base towards their vertex, is accounted for.

It is upon this principle that the water, elevated by the New River water-works, after having descended from a bason in a vertical pipe, and then after having flowed horizontally in a succession of pipes under the pavement, is raised up again, through another pipe, as high as the fountain at the Temple Garden. It is also upon this principle that a vessel may be filled either at the

mouth or at the bottom indifferently, provided that it is done through a pipe, the top of which is as high as the top of the vessel to be filled. Hence it follows, that when piers, aqueducts, reservoirs, or other hydraulic works for the retention of water are to be constructed, it becomes necessary to proportion their strength to the lateral pressure which they are likely to sustain, which becomes greater as the height of the water is more considerable. Nearly the same precautions are necessary to be taken with respect to what some philosophers call the grosser fluids, which also have a propensity to expand, as well on account of the smallness of their parts as from the small degree of cohesion which exists between them. Walls designed to support terraces ought to be sufficiently strong to resist the lateral pressure of the earth and rubbish which they are to sustain, since this pressure will be greater as the particles of earth, and of the other materials of which the terraces are composed, are less bound together, and in proportion as the terraces are more elevated.

3. All the parts of the same fluid are in equilibrium with each other, whether they are contained in one vessel or many, provided they communicate with each other; and their surfaces also are always in a plane parallel to the horizon.

This is a consequence of the principle which has been before established; for, since the particle k (fig. 11.) would be raised from the base towards the top, unless a column equal to the column $i\ k$, pressed upon it to retain it in its place; it follows that to be in equilibrium, the upper extremities of the two columns should be in the same horizontal plane, or in points equally distant from the centre of the earth; which points, however, cannot be found by a right line; for in the distance of a thousand fathoms there is about one foot difference in the perpendicular height. From this property of fluids it follows, that water conducted by pipes placed in the earth, will remount as high as the place whence it flowed, whatever the depth under ground through which it may have been conducted by the pipes. It is customary to allow half an inch of inclination in the length of six feet, to counteract the resistance produced by friction; but it is clear from what has been said, that this is not absolutely necessary, for however long the passage might be, the water would still ascend as high as the place whence it came, but it would require a little longer time to accomplish the ascent. We are enabled, upon this principle, to account for the springs which are sometimes found on the tops of mountains. Such waters flow from mountains still more elevated (whether they are far or near), by subterraneous canals. It follows from this principle, that if there are many reservoirs which communicate together, it is necessary only to see one of them to know the height of the water in the others; for it must necessarily be of the same height there as in all the rest.

From what has been observed, viz. that when all the parts of the same fluid are in equilibrium, their surfaces will also be in a plane parallel to the horizon, or, in other words, every part of the surface at an equal distance from the centre of the earth, it follows, that when the surface of water is very large, it becomes necessarily and sensibly convex. This is easily perceived at sea, where the masts of ships are observed at a distance before any other part of the ship can be distinguished.

It follows from the equal pressure of fluids in all directions, that the horizontal bottom of a vessel sustains just the pressure of a column of the fluid, whose base is the area of the bottom of the vessel, and whose perpendicular height is equal to the depth of the fluid. Thus in the vessel A B C fig. 12, the bottom B C does not sustain a pressure equal to the whole quantity of fluid contained in the vessel, but only of a column whose base is C B, and height C E. Also in the vessel F G H, the bottom G H, fig. 13, sustains a pressure equal to what it would be if the vessel were as wide at the top as bottom.

This leads us to notice what is called the hydrostatical paradox, which is thus expressed, "that a quantity of fluid, however small, may be made to counterpoise a quantity however large." Thus if to the wide vessel A B, fig. 14, the tube C D is attached, communicating with A B, and then water be poured into either of them, it will stand at the same height in both, consequently there is an equilibrium between them.

It may be thus illustrated: Let A B D G, fig. 15, represent any cylindrical vessel, to the inside of which is fitted a cover C, which will slide up and down without suffering any water to pass between the edges. In the cover is inserted a small tube, C F, which is open at top, and communicates with the inside of the cylinder beneath the cover at C. The cylinder is filled with water, and the cover put on. Then if the cover is loaded with a weight, as a pound, it will be depressed, and the water rise in the tube to E, and the weight will be sustained. If another weight be added, the water will rise to F, and the weight sustained, and so on, according to the weight added, and the length of the tube. Now the weight of the water in the tube is but a few grains, yet its lateral pressure serves to sustain as much as the weight of a column of water whose base is equal to that in the tube. Thus the column E C produces a pressure in the water contained in the cylinder, equal to what would have been produced by the column A a d D; and as this pressure is exerted equally every way, the cover will be pressed upwards with a force equal to the weight of A a d D; consequently if A a d D weigh a pound, E C will sustain a pound: and the like of any other heights and weights.

One of the most useful machines to show that a small quantity of water is capable of great pressure, is the hydrostatic bellows. This machine (fig. 16.) consists of two thick circular or oval boards, united to each other by leather, like a pair of common bellows, or a barber's puff. Into the lower board a pipe B, several feet high is fixed. Now, in showing experiments with this simple machine, which the reader might easily make, let water be poured into the pipe at its top, which will run into the bellows, and separate the boards a little: then, to show how much a small quantity of water will be able to effect by pressure, let weights be laid upon the upper board. If we pour more water into the pipe, it will as before run into the bellows, and raise up the board with all the weights upon it. And though the water in the tube should weigh in all but a single pound, yet the pressure of this small force upon the water below in the bel-

lows, will support the weights, which are perhaps a hundred pounds; nor will they have weight enough to make them descend, and conquer the weight of the water, by forcing it out of the mouth of the pipe.

Upon the principle of the upward pressure of fluids, a piece of lead may be made to swim in water, by immersing it to a proper depth, and keeping the water from getting above it. Let C D, fig. 17, be a glass tube open throughout, and G a flat piece of lead half an inch thick, fitted exactly to the lower end of the tube, but not to go within it. By means of the packthread L, the lead is held close to the bottom of the tube, and in this situation it is immersed in the water of the vessel K to somewhat more than eleven times its own thickness, because lead is more than eleven times heavier than water; then the thread L may be let go, but the lead will not fall, but be sustained by the upward pressure of the water below it. If some water be poured upon the lead, or if the tube be raised a little, the lead will fall by its own weight, which will then be too heavy for the pressure of the water round the tube, upon the column of water below it.

It is clear, from the foregoing principles, that a tun filled with water, may be burst by pressing it with some pounds additional weight of the fluid, through a tube, which may be supposed from twenty-five to thirty feet in height; for from what has been said, it necessarily follows, that the small quantity of water which the tube contains, presses upon the bottom of the tun as much as if a column of water had been added as wide as the tun itself, and as long as the tube, which would evidently be an enormous weight.

II. The effects of gravity on fluids of different densities will, from what has preceded, not be very difficult to comprehend.

It has been observed, that fluids are masses of small bodies moveable with great facility among themselves independently of each other, pressing separately, and in proportion to their masses.

It is proved also by chemical analysis, that even these minute particles are composed of particles still smaller. Now whether it results from the interposition of caloric in greater or less quantities, which we know is the cause of all fluidity, and also of the difference that exists between the incompressible and elastic fluids; or whether it may depend upon the shape or size of the particles, which, as in solid bodies, may increase or diminish the porosity, it is certain, that there is a considerable difference with respect to density in different fluids.

From this difference in point of density, a separation may be observed generally to take place, soon after mixing two heterogeneous fluids together, unless this effect is counteracted by some more powerful cause. It has been observed, that the particles, according to their weight, press independently of each other. Those therefore which have the most density, having more power to gain possession of the lower part of the vessel which contains them, oblige the others to yield and resign their situation; and hence a separation is effected. When oil and water, for instance, have been well shaken together, and afterwards the whole is left in a state of rest, the water, having more density than the oil, takes the lower position, and the oil rises to the surface. If this effect does not take place, it is owing to the intervention of one of the following causes: First, a kind of elective attraction, which may exist between the particles of different fluids, as when water and wine are mixed together, the water, though heavier than the wine, does not separate itself. Secondly, the viscosity of one of the substances, as when the whites of eggs are beaten together, and by that means a considerable quantity of air mixes with them; the air, though much lighter, has not power to disengage itself from the matter in which it is enveloped, in order to effect its escape.

If two fluids of different densities are placed in a state of equipoise with each other, and have the same base, their perpendicular heights above the horizon will be in a reciprocal ratio to their densities or specific gravities.

If, for example, mercury is put into an inverted siphon, and water is poured into one of the branches, in order to elevate the mercury in the other branch one inch above its level, it is necessary that the water should be about thirteen inches and an half high. The height of the water then will be thirteen times and a half that of the mercury; because the specific gravity of mercury is about thirteen times and a half as great as that of water.

This observation will also apply to the reciprocal action of air and water, or air and mercury upon each other. Many of the phenomena of hydrostatics and hydraulics are to be referred to the pressure of the atmosphere, for which we must refer to PNEUMATICS.

It is, however, proper on the present occasion, to call the reader's attention to some of the properties of this fluid, and he will easily remember, that as a fluid, air is possessed of gravity, and consequently presses upon all bodies which oppose it; and it is necessary to add, that like water, it presses in all directions. If, therefore, a small hole is made with a gimblet, either in the side or bottom of a cask or vessel which is quite full of liquor, it will not run out, because the external air which presses against the hole, sustains the liquor, which has not a sufficient height to overcome its pressure. Hence the necessity of a vent peg, to enable liquor to be drawn out of a full cask. The elasticity of the small quantity of air which is introduced at the vent presses the fluid, and overcomes the pressure of the air at the cock. There is an instrument in common use, called a valencia, for extracting small quantities of liquor out of the bung-holes of casks. It is a tube with a small aperture at the bottom and the top. When full, if the hole at the top is stopped with the thumb or finger, so as to prevent the pressure of the air at the top, the liquor will not run out of the hole at the bottom, being kept in by the force of the external air.

It is proper to observe, that all the effects which depend upon the pressure of air, take place in a room where the column of air is terminated by the ceiling, as well as without doors where the column of air has the whole height of the atmosphere; and the reason is, because the air in the room has a communication with that on the outside, supposing it to be only by means of the key-hole. Thus a barometer placed in a hall, will have its mercury as high as if it was placed in an open field.

The curious effects produced by siphons, all depend upon the pressure of the air.

A siphon is a bent tube, A B C, (fig. 3) made of glass, metal, &c. One branch of which A B, is shorter than the other B C. In order to make use of this instrument, place the extremity of the short branch in the vessel A, which may be supposed to contain any fluid matter, water for instance. If the air then is drawn out of the siphon (fig. 4), by means of the long branch x, the liquor will begin to flow, and will not cease while the short branch A B remains immersed in the fluid. It is easy to see that the pressure of the air upon the surface of the fluid in the vessel, is the cause of its discharge through the siphon. For suppose G F the confines of the atmosphere, all the points of the surface A of the liquor will be equally pressed by the column of air A F; if, therefore, at some point of this surface, the pressure is suspended, the liquor must flow at that point, because it finds less resistance there than in any other part; this is therefore the obvious reason why the siphon becomes full immediately after the air is drawn out at the extremity C.

If the two branches of the siphon were of equal lengths, as B A, B D, the flow through the bent tube would not take place; because the column of air D G which would resist in D, being of an equal height with that which presses at A, would also be in equilibrium with it, in the same manner as the two columns of the fluid B A, B D. But since B C, one of the legs, is longer than the other, though the column of the air G C, which answers to it, is really longer than that which presses in A; yet it is not capable of preventing the passage of the fluid. To understand this more perfectly, let us consider the column of air G C to be divided into two parts, one of which G D, would form an equipoise with the column of air F A, and would be capable of stopping the flow from the tube if the branch B C ended in D. The portion of fluid which fills the part D C of the siphon, will find no other resistance in C than one column of air D C of the same length with it, which is evidently very inferior to it in weight. This portion of fluid then flows out, because it greatly exceeds in weight the column of air which is opposed to it. But while it continues to flow, nothing sustains that which is above it, which flows necessarily, while the pressure of the air at A furnishes a new supply of fluid to replace that which runs out. It is by these means, that the water in the siphon continues to flow without intermission; because the resistance of the air in C is as much exceeded, as the length of the branch B C of the siphon exceeds that of the branch A B. In order to prove this, suppose there is added at C a tube to lengthen that branch, then it will plainly appear that in a given time more water will flow than would have been discharged without that augmentation to the branch B C.

Since it is the pressure of the air which elevates the fluid in the short branch B A, it follows, that the height of this branch is limited to thirty-two feet when the fluid is water, because the pressure of the atmosphere cannot elevate water higher; but when the liquor is mercury, the height of the short branch should not exceed thirty inches, because the atmosphere cannot sustain mercury at a greater height.

A siphon may be disguised in a cup, fig. 5, from which no liquor will flow, until it be raised above the bend of the siphon; but when the efflux once begins, it will continue to flow till the vessel be emptied. This has been called Tantalus's cup, because it is usual to place a hollow figure over the inner tube of such a length, that when the fluid has got nearly up to the lips of the figure, the siphon may begin to act, and empty the cup.

Intermitting springs, which puzzled philosophers formerly, are found to be natural siphons, which may be thus explained: Let A fig. 6, be part of a hill, within which there is a cavity B B, and from this cavity a vein, or channel running in the direction B C D. The rain that falls upon the side of the hill will sink and strain through the small pores and crevices in the hill, and fill the cavity B B with water. When the water rises to the level of C, the vein B C D will be full, and the water will run through it as a siphon, and will empty the cavity B B. It must then stop, and when the cavity is again filled, it will begin to run again.

III. The action of fluids on solid bodies immersed in them, has been treated of in SPECIFIC GRAVITY, which see.

To finish the subject of hydrostatics, however, we may add that it is evident that when a solid body is plunged into a fluid, it occupies a space in that fluid exactly equal to its own magnitude. The quantity of fluid then so displaced, either equals in density, and consequently in weight, the solid which displaced it; or, on the contrary, one of the two must weigh more than the other. In the last case, which is most common, the quantity by which the heavier body surpasses the lighter, is called the specific weight or gravity.

If a body is heavier than the fluid in which it is immersed, it is evident that it will sink to the bottom by its specific gravity. If a body is lighter than the same bulk of the fluid into which it is plunged, a part of it will swim, and the remaining part which is immersed displaces a quantity of fluid which weighs exactly as much as the whole of the solid body.

The instrument used for finding the specific gravities of bodies, is called the hydrostatic balance (fig. 18.) See SPECIFIC GRAVITY.

It differs very little from a common balance that is nicely made; only it has a hook at the bottom of one of the scales, on which different substances that are to be examined may be hung by horse-hairs, or silk threads, so as to be immersed in a vessel of water, without wetting the scale.

If a body thus suspended under the scale, at one end of the balance, be first counter-poised in air by weights in the opposite scale, and then immersed in water, the equilibrium will be immediately destroyed; then, if as much weight be put into the scale from which the body hangs, as will restore the equilibrium, without altering the weights in the opposite scale; that weight which restores the equilibrium, will be equal to the weight of a quantity of water as large as the immersed body; and if the weight of the body in air be divided by what it loses in water, the quotient will show how much that body is heavier than its bulk of water. Thus, if a guinea suspended in air, be counterbalanced by 129 grains in the opposite scale of the balance, and then, upon its being immersed in water, it becomes so much lighter as to require $7\frac{1}{4}$ grains put into the scale over it, to restore the equilibrium, it shows that a quantity of water of equal bulk with the guinea, weighs $7\frac{1}{4}$ grains, or 7.25; by which divide 129 (the

weight of the guinea in air), and the quotient will be 17.793; which shows that the guinea is 17.793 times as heavy as its bulk of water. And thus, any piece of gold may be tried, by weighing it first in air, and then in water; and if upon dividing the weight in air by the loss in water, the quotient comes out to be 17.793, the gold is good; if the quotient be 18, or between 18 and 19, the gold is very fine; but if it be less than 17, the gold is too much alloyed with other metal.

By this method, the specific gravities of all bodies that will sink in water, may be found; first weighing the body in air, then in water, and dividing the weight in air by the loss in water.

But as to those which are lighter than water, as most sorts of wood are, the following method must be taken: A sort of pincers, or tongs, must be provided, to retain the substance to be examined under water. First weigh the body in air; then having balanced the tongs in water, fix to it the body to be weighed, which being lighter than water, will raise the tongs, and cause the other scale to preponderate. Observe the loss of weight of the body in water, and proceed as before.

Their are some things that cannot be weighed in this manner, as quicksilver, fragments of diamonds, &c. which must be put into a glass bucket hanging to the scale.

HYDROSULPHURETS, in chemistry. Sulphureted or sulphurated hydrogen gas possesses the properties of an acid. It is absorbed by water, in considerable quantities, and the solution reddens vegetable blues; it combines also with alkalies and earths, and with several metallic oxides. The combinations which sulphureted hydrogen forms with bases have been called hydrosulphurets.

Sulphureted hydrogen combines with alkalies and earths, and forms with them compounds which may be distinguished by the following properties:

1. They are all soluble in water, and the solution is colourless.

2. When the solution is exposed to the air, it becomes green or greenish yellow, and deposits sulphur on the sides of the vessel in the state of a fine black crust.

3. After long exposure to the air, the solution becomes limpid and colourless; and on examination is found to contain only the sulphat of the base of the original hydrosulphuret.

4. The solution of the hydrosulphurets precipitate all metallic solutions; iron and lead, black; antimony, orange; arsenic, yellow.

The hydrosulphurets may be formed by dissolving or mixing the bases respectively with water, and causing sulphureted hydrogen gas to pass through them till they refuse to absorb any more. The excess of the gas is driven off by heating the solution. It is proper to cause the sulphureted hydrogen gas to pass through a small vessel of water before it reaches the base with which it is to combine, in order to separate any impurities with which it might be mixed. By this method solutions of the different hydrosulphurets in water may be obtained.

If these compounds be decomposed while they are colourless, by pouring upon them sulphuric acid, muriatic acid, or any other acid which does not act upon hydrogen, the sulphureted hydrogen gas exhales without the deposition of a single particle of sulphur; but if the hydrosulphuret has become yellow, some sulphur is always deposited during its decomposition, and the quantity of sulphur is proportioned to the deepness of the colour.

The yellow colour, therefore, which hydrosulphurets acquire by exposure to the atmosphere is owing to a commencement of decomposition. Part of the hydrogen of the sulphureted hydrogen abandons the sulphur, combines with the oxygen of the atmosphere, and forms water. By degrees, however, a portion of the sulphur is also converted into an acid; and when the proportion of sulphureted hydrogen is diminished, and that of the sulphur increased to a certain point, the sulphur and the hydrogen combine equally with oxygen.

If sulphuric or muriatic acids be poured upon a hydrosulphuret after it has been for some time exposed to the air, a quantity of sulphureted hydrogen gas exhales, sulphur is deposited, and after an interval of time sulphureous acid is disengaged. It is therefore sulphurous, and not sulphuric acid, which is formed while the hydrosulphuret spontaneously absorbs oxygen. This acid, however, is not perceptible till after a certain interval of time, when separated from the hydrosulphuret by means of another acid; because as long as it meets with sulphureted hydrogen a reciprocal decomposition takes place. The oxygen of the acid combines with the hydrogen of the gas, and the sulphur of both is precipitated.

The affinities of the alkalies and earths for sulphureted hydrogen appear from the experiments of Berthollet to be as follows:

Barytes,	Ammonina,
Potass,	Magnesia,
Soda,	Zirconia.
Lime,	

HYGROMETER, a machine, or instrument whereby to measure the degrees of dryness, or moisture of the atmosphere.

There are divers sorts of hygrometers; for whatever body either swells or shrinks, by dryness or moisture, is capable of being formed into an hygrometer. Such are woods of most kinds, particularly ash, deal, poplar, &c. Such also is catgut, the beard of a wild goat, &c. Stretch a hempen cord or lute string, as A B, (plate Hydrostatics, fig. 21.), along a wall, bringing it over a pulley, B; and to the other end D, fix a weight E; into which fit an index F. On the same wall fit a plate of metal H I, divided into any number of equal parts, and the hygrometer is complete. For it is known from experience that moisture sensibly shortens the length of cords or fiddle-strings; and that as the moisture evaporates, they return to their former length. The weight, therefore, in the present case, upon an increase of the moisture of the air, will ascend; and upon a diminution of the same, it will descend.

Hence, as the index F will show the spaces of ascent and descent; and those spaces are equal to the increments and decrements of the length of cord, or gut, A B D; the instrument will discover whether the air is more or less humid now, than it was at another given time.

But f a more sensible and accurate hygrometer is required, strain a whipcord or fiddle-string over several pullies, C, D, E, F, and G, fig. 22, and proceed as in

the former example. Nor does it matter whether the several parts of the cord are parallel to the horizon, as expressed in the figure, or perpendicular to the same.

The advantage of this above the former hygrometer, is, that we have a greater length of cord in the same compass; and consequently greater contraction or dilatation.

The following is much more lasting: Take a nice balance and place it in a sponge, or other body, which easily imbibes moisture, and let it be in equilibrio, with a weight hung at the other end of the beam. Now if the air become moist, the sponge becoming heavier, will preponderate; if dry, the sponge will be raised up. This balance may be contrived two ways; by either having the pin in the middle of the beam, with a slender tongue a foot and a half long, pointing to the divisions on an arched plate fitted to it; or, the other extremity of the beam may be made so long as to describe a large arch on a board placed for the purpose, as is represented in the figure.

To prepare the sponge, it may be necessary to wash it in water; and when dry again, in water or vinegar, in which sal ammoniac, or salt of tartar, has been dissolved, and let it dry again, then it is fit to be used.

A, fig. 23, represents a thin piece of sponge, so cut as to contain as large a superficies as possible. This hangs by a fine thread of silk, upon the beam B, and is exactly balanced from another thread of silk at D, strung with the smallest lead shot, at equal distances, and so adjusted as to cause the index to point at G, in the middle of the graduated arch F G H, when the air is in a middle state between the greatest moisture and the greatest dryness. I, shows a little table or shelf for that part of the silk and shot which is not suspended to rest upon.

Both Dr. Hales and Dr. Desaguliers contrived another form of sponge hygrometer, on this principle. They made an horizontal axis, having a small part of its length cylindrical, and the remainder tapering conically with a spiral thread cut in it, after the manner of the fuzee of a watch. See fig. 24. The sponge is suspended by a fine silk thread to the cylindrical part of the axis upon which it winds. This is balanced by a small weight W, suspended also by a thread, which winds upon the spiral fuzee. Then when the sponge grow sheavier, in moist weather, it descends and turns the axis, and so draws up the weight; which coming to a thicker part of the axis it becomes a balance to the sponge, and its motion is shown by an attached scale: and vice versa when the air becomes drier. Salt of tartar, or any other salt, or pot-ashes, may be put into the scale of a balance, and used instead of the sponge.

HYMEN. See Anatomy.

HYMENÆA, the bastard locust tree; a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 33d order, lomentaceæ. The calyx is quinquepartite; there are five petals, nearly equal; the style is intorted; the legumen full of mealy pulp. There is but one species, the courbaril, which is a large tree growing naturally in the Spanish West Indies. The trunk is covered with a light ash-coloured bark, is often more than sixty feet high, and three in diameter. The seeds are covered with a light brown sugary substance, which the Indians scrape off and eat with great avidity, and which is very agreeable. At the principal roots under ground, is found collected in large lumps a yellowish red transparent gum, which dissolved in rectified spirit of wine affords a most excellent varnish, and is the gum anime of the shops.

HYMENOPTERA, derived from ὑμην membrane and πτερον wing, in the Linnæan system of natural history, is an order of insects having four membranaceous wings, and the tails of the females are furnished with stings, which in some are used for instilling poison, and in others for merely piercing the bark and leaves of trees, and the bodies of other animals, in which they deposit their eggs.

HYOBANCHE, a genus of the angiospermia order, in the didynamia class of plants. The calyx is heptaphyllous; the corolla ringent, with no under lip. The capsule bilocular, and polyspermous. There is one species, a parasitical plant of the Cape.

HYOIDES. See Anatomy.

HYOSCYAMUS, henbane, in botany, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 28th order, luridæ. The corolla is funnel-shaped and obtuse; the stamina inclining to one side; the capsule covered and bilocular. There are eight species, one of which, viz. the niger, or common henbane, is a native of Britain. It grows on road-sides, and among rubbish. It is a biennial plant, with long fleshy roots which strike deep into the ground, sending out several large soft leaves, deeply flashed on their edges: the following spring the stalks come up, which are about two feet high, with yellow flowers standing on one side in a double row, sitting close to the stalks alternately. The seeds, leaves, and roots of this plant, as well as of all other species of this genus, are poisonous: and many well-attested instances of their bad effects are recorded; madness, convulsions, and death, being the common consequence. In a smaller dose they occasion giddiness and stupor. It is said that the leaves scattered about a house will drive away mice. The juice of the plant evaporated to an extract is prescribed in some cases as a narcotic; in which respect undoubtedly it may be a powerful medicine if properly managed. The dose is from half a scruple to half a dram. The roots are used for anodyne necklaces. Goats are not fond of the plant; horses, cows, sheep, and swine refuse it.

HYOSERIS, a genus of the polygamia æqualis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. The receptacle is naked, the calyx nearly equal; the pappus hairy, or scarce perceptible. There are ten species, resembling dandelion.

HYOTHYROIDES. See Anatomy.

HYPALLAGE, among grammarians, a species of hyperbaton, consisting in a mutual permutation of one case for another. Thus, Virgil says, "dare classibus austros," for "dare classes austris;" and again, "necdum illis labra admovi," for "necdum illa labris admovi."

HYPECOUM, wild cummin; a genus of the digynia order, in the tetrandria class of plants; and in the natural method ranking under the 24th order, corydales. The calyx is diphyllous; the petals four; the exterior two larger and trifid; the fruit a pod. There are three

species, all of them low herbaceous plants with yellow flowers. The juice of these plants is of a yellow colour, resembling that of celandine, and is affirmed by some eminent physicians to be as narcotic as opium. From the nectarium of the blossom the bees collect great quantities of honey.

HYPERBATON, in grammar, a figurative construction inverting the natural and proper order of words and sentences. The several species of the hyperbaton are the anastrophe, the hysteron-proteron, the hypallage, synchysis, tmesis, parenthesis, and the hyperbaton, strictly so called.

Hyperbaton, strictly so called, is a long retention of the verb, which completes the sentence, as in the following example from Virgil:

> Interea *reges:* ingenti mole Latinus
> Quadrijugo vehitur curru, cui tempora circum
> Aurati bis sex radii fulgentia cingunt
> Solis avi specimen: bigis it Turnus in albis,
> Bina manu lato crispans hastilia ferro:
> Hinc pater Æneas Romanæ stirpis origo,
> Sidereo flagrans clypeo et cœlestibus armis;
> Et juxta Ascanius magnæ spes altera Romæ:
> *Procedunt* castris.

HYPERBOLA, in geometry, the section of a cone made by a plane, so that the axis of the section inclines to the opposite leg of the cone, which in the parabola is parallel to it, and in the ellipsis intersects it. The axis of the hyperbolical section will meet also with the opposite side of the cone, when produced above the vertex. See Conic Sections.

HYPERBOLE, in rhetoric, a figure, whereby the truth and reality of things are excessively either enlarged or diminished.

HYPERBOLIC Cylindroid, is a solid figure, whose generation is given by Sir Christopher Wren, in the Philosophical Transactions. Thus, two opposite hyperbolas being joined by the transverse axis, and through the centre a right line being drawn at right angles to that axis; and about that, as an axis, the hyperbolas being supposed to revolve; by such revolution, a body will be generated, which is called the hyperbolic cylindroid, whose bases, and all sections parallel to them, will be circles. In a subsequent transaction, the same author applies it to grinding of hyperbolical glasses; affirming, that they must be formed this way, or not at all. Hyperbolic leg of a curve, is that which approaches infinitely near to some asymptote. Sir Isaac Newton reduces all curves, both of the first and higher kinds, into those with hyperbolic legs, and those with parabolic ones.

Hyperbolic line is used by some authors for what we call the hyperbola itself. In this sense, the plane surface, terminated by the curve line, is called the hyperbola, or hyperbolic space; and the curve line that terminates it the hyperbolic line.

HYPERBOLOIDES, are hyperbolas of the higher kind, the nature of which is expressed by this equation: $ay^{m \times n} = bx^{m} (a + x^{n})$: especially if $m > 1$, or $n > 1$, e. g. $ay^3 = bx^2 (a + x)$.

HYPERICUM, St. John's wort; a genus of the polyndria order, in the polydelphia class of plants; and in the nateral method ranking under the 20th order, rotaceæ. The calyx is quinquepartite; the petals five; the filaments many, and coalited at the base into five pencils; the seed-vessel is a pencil. Of this genus there are 57 species, most of them hardy deciduous shrubs. The most remarkable are, 1. The hircinum, or stinking St. John's wort. Of this there are three varieties; one with strong stalks, six or eight feet high, broad leaves and large flowers; the other with strong stalks, broad leaves, and without any disagreeable odour; the third has variegated leaves. All these varieties are shrubby, and flower in June and July in such numerous clusters, that the shrubs appear covered with them; and produce abundance of seed in autumn. 2. The canariensis has shrubby stalks, and at the end of the branches, clusters of yellow flowers appearing in June and July. 3. The ascyron, or dwarf American St. John's wort, has spreading roots, sending up numerous slender square stalks, a foot long, and at the end of the stalks large yellow flowers. 4. The androsæmum, commonly called tutsan, or park-leaves, has clusters of small yellow flowers appearing in July and August, and succeeded by roundish berry-like black capsules. This grows naturally in many parts of Britain. 5. The balearicum, or water-leaved St. John's wort, is a native of Majorca, and has a shrubby stalk, with reddish scarified branches, small oval leaves warted underneath, and large yellow flowers appearing great part of the year. 6. The monogynum, or one-styled China hypericum, has a shrubby purplish stalk, about two feet high, and clusters of small yellow flowers, with coloured cups, and only one style, flowering the greatest part of the year.

The tutsan long held a place in the medicinal catalogues; but its uses are very little thought of at present. The leaves given in substance are said to destroy worms. By distillation they yield an essential oil. The flowers tinge spirits and oils of a fine purple colour. Cows, goats, and sheep eat the plant; horses and swine refuse it. The dried plant boiled in water with alum dyes yarn of a yellow colour; and the Swedes give a fine purple tinge to their spirits with the flowers.

HYPHYDRA, a genus of the class and order monoecia gynandria; the male cal. is one-leafed; cor. none; stam. six. The female no cal. or cor.; caps. one-celled. There is one species, a little aquatic plant of Guiana, of no note.

HYPNUM, feather-moss; a genus of the natural order of musci, belonging to the cryptogamia class of plants. The anthera is operculated, or covered with a lid; the calyptra smooth; the filament lateral, and rising out of a perichætium, or tuft of leaflets different from the other leaves of the plant. There are fifty species, many of them natives of Great Britain; none of them, however, have any remarkable property, except the proliferum and parietinum. The first is of a very singular structure, one shoot growing out from the centre of another: the veil is yellow and shining: the lid with a kind of long bill; the leaves not shining; sometimes of a yellowish, and sometimes of a deep green. This moss covers the surface of the earth in the thickest shades, through which the sun never shines, and where no other plant can grow. The second has shoots nearly flat and winged, undivided for a considerable length, and the leaves shining; but the

old shoots do not branch into new ones as in the preceding species. It grows in woods and shady places; and, as well as the former, is used for filling up the chinks in wooden houses.

HYPOCAUSTUM, among the Greeks and Romans, a subterraneous place, wherein was a furnace, to heat the baths.

HYPOCHÆRIS, hawk's-eye; a genus of the polygamia æqualis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. The receptacle is paleaceous; the calyx a little imbricated; the pappus glomy. There are five species; none of which have any remarkable property, except the maculata, or spotted hawk's-eye. It is a native of Britain, and grows on high grounds. The leaves are boiled and eaten like cabbage. Horses are fond of this plant when green, but not when dry. Cows, goats, and swine eat it; sheep are not fond of it.

HYPOCHONDRIA. See ANATOMY and MEDICINE.

HYPOTHENUSE, in geometry, the longest side of a right-angled triangle; or it is that side which subtends the right angle.

Euclid, lib. I. proposition XLVII. demonstrates, that, in every rectilinear right-angled triangle, the square of the hypothenuse is equal to the squares of both the other sides.

This celebrated problem was discovered by Pythagoras, who is said to have sacrificed a hecatomb to the Muses, in gratitude for the discovery.

HYPOXIS, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the 10th order, coronariæ. The corolla is divided into six parts, and persisting, superior; the capsule narrowing at the base; the calyx a bivalved glume. There are fourteen species, bulbs of America and the Cape.

HYRAX. Hyrax, a genus of quadrupeds of the glires order. The generic character is, front teeth in the upper jaw two, broad, somewhat distant; in the lower jaw four, broad, flat, twice crenated; grinders large, four on each side in both jaws; fore-feet with four toes; hind-feet with three toes; tail none; clavicles none. This genus is distinguished from all the rest of the glires by the remarkable circumstance of having four teeth in the lower jaw instead of two: these lower teeth are also of a different structure from the upper, being broad, short, and crenated or denticulated at the top: the upper teeth in this genus are also less sharp or pointed than in the rest of the glires. In other particulars the genus hyrax seems most nearly allied to that of cavia. The most remarkable species are:

1. Hyrax Capensis is a native of mountainous situations about the Cape of Good Hope; residing in the hollows of rocks, and leaping with great agility about the prominences of the irregular regions it frequents, though its general or walking pace is not remarkably quick. Its size is nearly that of a rabbit, and in colour it much resembles that animal, but is whitish beneath. It is said to be known at the Cape by the name of rock badger, but Mr. Allamand observes, that this is an improper name, since the structure of its feet evidently shows that it has no power of digging or burrowing. It is a diurnal animal, and by night retires into the cavities of rocks, &c. This animal appears to be easily tamed, and in that state is observed to be remarkably cleanly, and of a lively and active disposition; leaping almost as readily and with as much security as a cat.

2. Hyrax Syriacus, or Syrian hyrax, seems to have been first clearly described by Mr. Bruce, in the appendix to his celebrated Abyssinian Travels. It is found in Ethiopia, in the caverns of the rocks, or under the great stones in the Mountain of the Sun, behind the queen's palace at Koscam. It is also frequent in the deep caverns in the rock in many other parts of Abyssinia. It does not burrow or make holes, as the rat and rabbit.

In the place of holes, it seems to delight in less close, or more airy places, in the mouths of caves, or clefts in the rock. They do not stand upright upon their feet, but seem to steal along as in fear, their belly being nearly close to the ground, advancing a few steps at a time, and then pausing. They have something very mild, feeble, and timid, in their deportment; are gentle and easily tamed, though, when roughly handled at the first, they bite very severely. The hyrax is supposed to be the animal erroneously called by our translators of the bible cuniculus, the rabit or coney. See Plate LXXIV. Nat. Hist. fig. 230.

3. Hyrax Hudsonius. Its colour is a cinereous brown, with the ends of the hairs white. It is a native of Hudson's Bay. Its size is nearly that of a common marmot; the feet are tetradactylous; of a similar form to those of the cape hyrax, but have rounded claws on all the toes.

HYSSOPUS, hyssop, a genus of the gymnospermia order, in the didynamia class of plants; the cor. has the lower lip with a small crenate segment; stam. straight, distant. There are three species; but only one of them, viz. the officinalis, or common hyssop, is cultivated for use. Besides possessing the general virtues of aromatics, they have been supposed useful in humoral asthmas, coughs, and other disorders of the lungs; and are said to promote expectoration.

HYSTERICS. See MEDICINE.

HYSTRIX. Porcupine, a genus of quadrupeds, of the order glires. The generic character is front-teeth two, both in the upper and under jaw, obliquely cut; grinders eight; body covered with spines intermixed with hairs; four toes on the fore-feet; five on the hind.

1. Common porcupine. From their obvious external characters alone, without reference to the form and disposition of the teeth, the porcupine and the hedgehog might be placed together; but such is the dissimilarity of these organs, that the one must of necessity belong to the Linnæan order feræ, and the other to that of glires.

The singular appearance of the porcupine, so different from that of the generality of quadrupeds, must in the earliest ages have attracted the attention even of the most incurious; the variegated spines or quills with which it is covered, naturally suggesting the idea of a fierce and formidable animal: it is, however, of a harmless nature, and the quills are merely defensive weapons, which, when disturbed or attacked, the animal erects, and thus endeavours to repel his adversary.

The general length of the porcupine is about two feet from head to tail, and that of the tail about four inches. The upper parts of the animal are covered with long, hard, and sharp quills; those towards the middle and

hind part of the body being longer than the rest, and measuring from nine or ten to twelve or fifteen inches in length: they are very sharp-pointed, and are variegated with several alternate black and white rings: the root, or point of attachment, is small: the head, belly, and legs, are covered with strong dusky bristles, intermixed with softer hairs: on the top of the head the hairs are very long, and curved backwards in the manner of a ruff or crest: the ears are short and rounded: the nose blunt; the upper lip divided by a strongly-marked furrow; the two fore-teeth, both above and below, extremely large and strong: the fore feet have four toes; the hind feet five; all armed with strong crooked claws: the tail is covered with short and rather flattish quills, which are often abrupt or truncated, rather than pointed at the extremities. This animal is a native of Africa, India, and the Indian islands: it is also found in some of the warmer parts of Europe, and is said to be not very uncommon in Italy and Sicily; but is supposed to have been originally imported into those parts of Europe from other regions.

The power of darting its quills with great violence, and to a considerable distance, so confidently ascribed to the porcupine, has been doubted; but it is surely not improbable that the porcupine possessing, like other quadrupeds, the power of corrugating or shaking the general skin of its body, may sometimes by this motion cast off a few of its loose quills to some distance, and thus slightly wound any animal that may happen to stand in its way; and this may have given rise to the popular idea of its darting them at pleasure against its enemies. That it really does cast them off occasionally with some degree of violence there is no reason to doubt. The strongest and shortest of the quills are most easily detached, and are those which the animals dart against the hunters, by shaking their skin as dogs do when they come out of the water.

The porcupine feeds principally on roots, fruits, barks, and other vegetable substances: it inhabits holes or subterraneous retreats, which it is said to form into several compartments or divisions, leaving only a single hole or entrance. It sleeps much by day, and makes its excursions for food during the night. The female produces two young at a birth, and these, if taken early, are said to be easily tamed.

The porcupine admits of considerable variety as to the length and proportion of the quills in different specimens and from different countries: the long crested bristles on the back of the head, in particular, are much more conspicuous in some than in others. See Plate LXXIV. Nat. Hist. fig. 231.

2. Hystrix prehensilis, is an American species, and is found in many of the hotter parts of that continent; particularly in Brazil, where it inhabits woods, and climbs trees; clinging occasionally to the branches by its tail, in the manner of some of the opossums and monkies. It is said to feed not only on fruits of various kinds, but also on birds. It sleeps during the greater part of the day, concealing itself in the hollows of trees, or beneath their roots. Its voice, according to Marcgrave, resembles the grunting of a pig. Its general length is about a foot, and the tail about eighteen inches. The whole animal, except on the belly and insides of the limbs, is covered with short, strong, and very sharp spines, of which the longest measure three inches, and are white, barred towards the points with black. The colour of the hair with which the under parts are covered is a dusky brown. The head is small; the nose extremely blunt; and the teeth very large and strong: the ears short, moderately large, and rounded; the feet have four toes each, with strong claws, and a tubercle in place of a fifth toe; the tail is covered with spines for about a third part of its length; the remainder being nearly naked; and strongly prehensile.

3. Hystrix Mexicana. The Mexican porcupine, which is placed as a variety of the hystrix prehensilis in the Gmelinian edition of the Systema Naturæ, seems to be justly considered by Mr. Pennant as a distinct species. It is as large, according to Hernandes, as a middle-sized dog, and is of a dusky brown colour, with very long bristles intermixed with the fur. This animal inhabits the hilly parts of Mexico, residing in woods, and feeding, like the former, on fruits, &c. It is said to be easily tamed.

4. Hystrix macroura. The iridescent porcupine is an animal of a very extraordinary appearance. It is of a very thick form, and is coated with short, stiff, needle-like bristles, or small spines, which, according to the different directions of the light, exhibit changeable colours, appearing either of a gilded green, or of a reddish tinge. If we except the gilded, or cape mole, it seems to be almost the only quadruped yet known with changeable-coloured hair.

5. Hystrix fasciculata is a native of Malacca. It differs from the common porcupine in several particulars, and especially in the form and length of its tail, which is naked, scaly, about a third of the length of the body, and terminated by a tuft of long flat hairs, or rather small white laminæ, resembling strips of parchment. The body measures fifteen or sixteen inches, and is consequently less than that of the European porcupine.

This species, like others of its genus (which nature seems to have provided with defensive weapons only), possesses a kind of instinctive fierceness: when approached, it stamps with its feet, and appears to inflate itself, raising and shaking its quills. It sleeps much by day, and is active only by night. It eats in a sitting posture, holding apples and other fruits between its paws, peeling them with its teeth.

6. Hystrix dorsata is a native of the northern parts of America, and is not uncommon in Canada. It is a short thick-bodied animal, approaching somewhat to the form of a beaver, and is remarkable for the length and fulness of its fur, which is soft, of a dusky brown colour, and intermixed with longer and coarser hairs with whitish tips. Edwards compares the size to that of a fox, though the shape is widely different. The spines are nearly hid in the fur, and are only visible on a close inspection: they are situated on the head and upper parts, as well as on the tail: the longest are those on the back, which measure about three inches, while those on the other parts are proportionally shorter: they are strong and sharp-pointed, and so formed as to appear, when examined with a magnifier, as if barbed at the tips with numerous, small, reversed points or prickles, and are so slightly attached to the skin as to be loosened with great ease: and the animal will sometimes purposely brush against the legs of those who disturb it, leaving several of the spines sticking in the skin.

It is said to feed principally on the bark of the juniper tree. It drinks by lapping, in the manner of a dog. It resides in holes under the roots of trees, on which, like some others of this genus, it often climbs, and is thus killed by the American Indians, who consider it as a useful article of food: they also use the quills by way of fringes, and for the purpose of ornamenting their boxes, &c.

I.

I, the ninth letter of the alphabet, used as a numeral, signifies no more than one, and stands for so many units as it is repeated times: thus, I, one; II, two; III, three, &c. and when put before a higher numeral, it subtracts itself, as IV, four; IX, nine, &c. but when set after it, so many are added to the higher numeral, as there are I's added; thus VI is 5 + 1, or six; VII, 5 + 2, or seven; VIII, 5 + 3, or eight. The ancient Romans likewise used IƆ for 500, CIƆ for 1000, IƆƆ for 5000, CCIƆƆ for 10,000, IƆƆƆ for 50,000, and CCCIƆƆƆ for 100,000. Farther than this, as Pliny observes, they did not go in their notation; but when necessary, repeated the last number, as CCCIƆƆƆ, CCCIƆƆƆ for 200,000; CCCIƆƆƆ, CCCIƆƆƆ, CCCIƆƆƆ for 300,000; and so on.

IAMBIC, in ancient poetry, a sort of verse, so called from its consisting, either wholly or in great part, of iambuses.

IAMBUS, in ancient poetry, a simple foot consisting of a short and a long syllable.

IBERIS, *sciatica cresses*, or *candy-tuft*, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. The corolla is regular; the two exterior petals larger than the interior ones: the silicula polyspermous, emarginated. There are 14 species. The most remarkable are: 1. The umbellata, or common candy-tuft, a well-known annual. 2. The amara, or bitter candy-tuft. 3. sempervirens, commonly called tree candy-tuft. 4. The semperflorens, with white flowers in umbels at the ends of the branches, appearing at all times of the year.

IBEX, in zoology. See Capra.

IBIS. See Tantalus.

ICE. See Water, and Cold.

Ice-house, a building contrived to preserve ice for the use of a family in the summer season. It is generally sunk some feet in the ground in a very shady situation, and covered with thatch.

ICELAND-AGATE, a precious stone met with in the islands of Iceland and Ascension, employed by the jewellers as an agate, though too soft for the purpose. It is supposed to be a volcanic product; being solid, black, and of a glassy texture. When held between the eye and the light, it is semitransparent, and greenish, like the glass bottles which contain much iron. In the islands which produce it, such large pieces are met with that they cannot be equalled in any glass-house.

ICHNEUMON *fly*, the name of a genus of flies of the hymenoptera order. The generic character is, mouth with jaws, without tongue; antennæ with more than thirty joints; abdomen in most species footstalked; piercer exserted, with a cylindric bivalve sheath. The animals of this genus provide for the support of their offspring in a manner highly extraordinary, depositing their eggs in the bodies of other living insects, and generally in those of caterpillars. These eggs in a few days hatch, and the young larvæ, which resemble minute white maggots, nourish themselves with the juices of the unfortunate animal, which however continues to move about and feed till near the time of its change to a crysalis, when the young brood of ichneumon-larvæ creep out by perforating the skin in various places, and each spinning itself up in a small oval silken case, changes into a crysalis, the whole number forming a groupe on the shrivelled body of the caterpillar which had afforded them nourishment; and after a certain period emerge in the state of complete ichneumons.

It was the want of an exact knowledge of the genus ichneumon that proved so considerable an embarrassment to the older entomologists, who having seen a brood of ichneumons proceed from the chrysalis of a butterfly, could not but conclude that the production of insects was rather a variable and uncertain operation of nature than a regular continuation of the same species. The observations however of Swammerdam, Malphigi, Roesel, and others, have long since removed the difficulties which formerly obscured the history of the insect tribe. See Plate LXXIV. Nat. Hist. figs. 232, 233. It is said there are no less than 415 species of this insect.

ICHNOGRAPHY, in perspective, the view of any thing cut off by a plane parallel to the horizon, just at the base of it. Among painters it signifies a description of images, or of ancient statues of marble and copper, of busts and semi-busts, of paintings in fresco, mosaic works, and ancient pieces of miniature.

Ichnography. See Architecture.

ICHTHYOCOLLA. See Accipenser, and Gelatina.

ICHTHYOLITHUS, in natural history, the body or parts of a fish changed into a fossil substance. Four species are enumerated. The niger is found in a black slate in the island of Sheppey, and various parts of Wales, Germany, &c. impregnated with bitumen, pyritaceous matter, or oxide of copper. The fishes resemble the eel, swordfish, cod, flat fish, perch, roach, dace, makarel, mullet, carp, &c. The albidus is found in various parts of England, on mount Libanus in Palestine, in the ecclesiastical territories of Italy, in Switzerland, Bavaria, &c. The fishes are rarely of the sea kind, but usually those that inhabit the fresh water. They are seldom found whole, but in different parts, as the head, gill-covers, and other bones, fins, tails, tendrils, or scales, in a grey slaty swinestone, or impressed on shistose marble, and sometimes penetrated with bitumen.

ICHTHYOLOGY, ἰχθυολογια, the science of fishes, or

that branch of zoology which treats of fishes. See Fish, and Comparitive Anatomy.

ICONOCLASTS, in church history, an appellation given to those persons who in the eighth century opposed image-worship, and still given by the church of Rome to all christians who reject the use of images in religious matters.

ICOSAHEDRON, in geometry, a regular solid, consisting of 20 triangular pyramids, whose vertices meet in the centre of a sphere, supposed to circumscribe it, and therefore have their height and bases equal; wherefore the solidity of one of those pyramids multiplied by 20, the number of bases, gives the solid content of the icosahedron.

If fig. 127, Plate LXXII. Miscel. be nicely drawn on pasteboard, cut half through, and then folded up neatly together, it will represent an icosahedron. See fig. 128.

To form an icosahedron, describe upon card paper 20 equilateral triangles; cut it out by the extreme edges, and cut all the other lines half-through; then fold up by these edges, and the solid will be formed. The linear edge of the icosahedron being A, then the surface will be $5A^2\sqrt{3} = 8.660\ A^2$, and the solidity $\frac{5}{6}\ A^3 \sqrt{\frac{7 + 3\sqrt{5}}{2}} = 2.1817\ A^3$.

ICOSANDRIA, from εικοσι, "twenty," and ανηρ, "a man or husband;" the name of the 12th class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which are furnished with 20 or more stamina, that are inserted into the inner side of the calyx or petals. See Botany.

IDES, *idus*, in the ancient Roman calendar, were eight days in each month, the first of which fell on the 15th of March, May, July, and October, and on the 13th day of other months. They were reckoned backwards: thus they called the 14th day of March, May, July, and October, and the 12th of the other months, the pridie idus, or the day before the ides; the next preceding day, they called the tertio idus; and so on, reckoning always backwards, till they came to the nones. This method of reckoning time is still retained in the chancery of Rome, and in the calendar of breviary.

IGNATIA, a genus of the monogynia order, in the pentandria class of plants. The calyx is five-toothed; the corolla is long; the fruit an unilocular plum, with many seeds. There are two species, the principal of which is the amara, a native of India. The fruit of this tree contains the seeds called St. Ignatius's beans. According to some, it is from this plant that the columbo root is obtained.

IGNIS Fatuus, a common meteor, chiefly seen in dark nights about meadows, marshes, and other moist places, as also in burying-grounds, and near dung-hills. It is known among the people by the appellations, Will with a wisp, and Jack with a lantern. See Meteors.

IGNITION. See Caloric, and Chemistry.

IGNORAMUS, was formerly indorsed by the grand jury on the back of a bill, for which they did not find sufficient evidence; but now, since the proceedings were in English, they indorse "no bill," or "not a true bill," or which is the better way, "not found."

IGUANA. See Lacerta.

ILEX, *the holm or holly tree*, a genus of the tetragynia order, in the tetrandria class of plants, and in the natural method ranking under the 43d order, dumosæ. The calyx is quadridentated; the corolla rotaceous; there is no style; the berry is monospermous. There are 16 species of this genus; but the most remarkable is the aquifolium, or common holly. Of this there is a great number of varieties with variegated leaves, which are propagated by the nursery gardeners for sale. The best of these varieties are the painted-lady holly, British holly, Bradley's best holly, phyllis or cream holly, milkmaid holly, Pritchet's best holly, gold-edged hedgehog holly, Chyney's holly, glory-of-the-west holly, Broaderick's holly, Partridge's holly, Herefordshire white holly, Blind's cream holly, Longstaff's holly, Eales's holly, silver-edged hedgehog holly. All these varieties are propagated by budding or grafting them upon stocks of the common green holly.

Sheep in the winter are fed with croppings of holly. Birds eat the berries. The bark fermented, and afterwards washed from the woody fibres, makes the common birdlime. The plant makes an impenetrable fence, and bears cropping; however, it is not found in all respects to answer for this purpose equally well with the hawthorn. The wood is used in fineering, and is sometimes stained black to imitate ebony. Handles for knives, and cogs for mill-wheels, are made of it. Mr. Miller says, he has seen the floor of a room laid with compartments of holly and mahogany, which had a very pretty effect.

ILIAC Passion. See Medicine.

ILLECEBRUM, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. The calyx is pentaphyllous, and cartilaginous; there is no carolla; the stigma is simple; the capsule quinquevalved, and monospermous. There are 21 species, of which the most remarkable are the paronychia and the capitatum. Both these have trailing stalks near two feet long, which spread on the ground, furnished with small leaves like those of knot-grass. The heads of the flowers come out from the joints of the stalks, having neat silvery bracteæ surrounding them, which make a pretty appearance. Their flowers appear in June, and there is generally a succession of them for at least two months; and when the autumn proves warm, they will ripen their seeds in October.

ILLICIUM, a genus of the pentagynia order, in the dodecandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is tetraphyllous, and deciduous: there are eight petals, and eight petaloid subulated nectaria. There are 16 stamina with bifid antheræ; the capsules are ovate, compressed, and monospermous. There are two species, viz. 1. The floridanum, with red flowers, and very odorous fruit. It is a native of China. 2. The anisatum, a native of the woods of China and Japan. The first is a very ornamental plant, and now common in our greenhouses.

ILLUMINATING, a kind of minature-painting, anciently much practised for illustrating and adorning books. Besides the writers of books, there were artists whose profession was to ornament and paint manuscripts, who were called illuminators: the writers of books first finished their part, and the illuminators embellished them with ornamented letters and paintings. We fre-

quently find blanks left in manuscripts for the illuminators, which were never filled up. Some of the ancient manuscripts are gilt and burnished in a style superior to later times. Their colours were excellent, and their skill in preparing them must have been very great.

IMAM, a name applied by the Mahometans to him who is head of the congregation in their mosques; and by way of eminence to him who has the supreme authority both in respect to spirituals and temporals.

IMBEZLE, Embezzle, signifies to steal, pilfer, or purloin, and also to waste and diminish goods, &c. entrusted to a person's charge and care. Embezzlers of wool forfeit double damages, and may be committed to the house of correction till paid; and servants embezzling their masters' goods to the value of 40*s.* are deemed guilty of felony without benefit of clergy.

IMBRICATED, among botanists, an appellation given to such leaves of plants, as are placed over one another like the tiles of a house. The term is likewise applied to some of the heart-shells, from their being ridged transversely in the same manner.

IMMEMORIAL: in a legal sense, a thing is said to be of time immemorial, or time out of mind, that was before the reign of king Edward II.

IMMERSION, in astronomy, is when a star or planet is so near the sun with regard to our observations, that we cannot see it; being enveloped and hid in the rays of that luminary. It also denotes the beginning of an eclipse of the moon, or that moment when the moon begins to be darkened, and to enter into the shadow of the earth; and the same term is also used with regard to an eclipse of the sun, when the disk of the moon begins to cover it. In this sense emersion stand opposed to immersion, and signifies the moment wherein the moon begins to come out of the shadow of the earth, or the sun begins to show the parts of his disk which were hid before. Immersion is frequently applied to the satellites of Jupiter, and especially to the first satellite; the observation of which is of so much use for discovering the longitude. The immersion of that satellite is the moment in which it appears to enter within the disk of Jupiter, and its emersion the moment when it appears to come out. The immersions are observed from the time of the conjunction of Jupiter with the sun, to the time of his opposition; and the emersions from the time of his opposition to his conjunction.

IMPALED, in heraldry: when the coats of a man and his wife who is not an heiress are borne in the same escutcheon, they must be marshalled in pale; the husband's on the right side, and the wife's on the left: and this the heralds call baron and feme, two coats impaled. See Heraldry.

IMPARLANCE, in law, a petition in court for a day to consider or advise what answer the defendant shall make to the plaintiff's action, and is the continuance of the cause till another day, or a longer time given by the court.

An imparlance is general or special; general is when it is entered in general terms, without any special clause therein; special is where the defendant desires a further day to answer. And this last imparlance is of use to plead some matters, which cannot be pleaded after a general imparlance.

It is said that imparlance was formerly from day to day, but now it is from one term to another. In case the plaintiff amends his declaration after the same is delivered or filed, the defendant may in course impart to the next term afterwards, unless the plaintiff pays costs; but if he does, and they are accepted, the defendant may not have an imparlance. Likewise the not delivering a declaration in time is sometimes the cause of imparlance; and when the plaintiff declares, yet does not proceed in three terms after, in such case the defendant may imparl to the next succeeding term. But there are divers cases wherein imparlances are not to be given: as where a person is sued by an attorney or any other privileged person of the court, in an assize, one may not imparl, except good cause be given; nor shall there be imparlance in action of special clausum fregit, &c.

IMPATIENS, the common balsam, or noli me tangere, a genus of the class and order syngensia monogamia. The calyx is two-leaved; corolla five-petalled, irregular, with a cowled nectarium; capsule superior, five-valved. There are twelve species, all annuals. The noli me tangere is indigenous to Britain, and has its specific name from the capsule shooting forth its seeds to a great distance when touched.

IMPEACHMENT, is the accusation and prosecution of a person in parliament, for treason or other crime and misdemeanor. An impeachment before the lords by the commons of Great Britain, is a presentment to the most high and supreme court of criminal jurisdiction, by the most solemn, grand inquest of the whole kingdom. A commoner cannot be impeached before the lords for any capital offence, but only for high misdemeanors; but a peer may be impeached for any crime. The articles of impeachment are a kind of bill of indictment, found by the house of commons, and afterwards tried by the lords, who are in cases of misdemeanors considered not only as their own peers, but as the peers of the whole nation. By stat. 12 and 13 W. c. 2. no pardon under the great seal shall be pleadable to an impeachment by the commons in parliament. 4 Black. 259.

In the case of Warren Hastings, in the year 1791, it was solemnly determined that impeachments do not abate by a dissolution of parliament.

Impeachment *of waste,* signifies a restraint from committing of waste upon lands and tenements; and therefore he that has a lease without impeachment of waste, has by that a property or interest given him in the houses and trees, and may make waste in them without being impeached for it, that is, without being questioned or demanded any recompence for the waste done. 11 Rep. 82.

IMPEDIMENTS in law. Persons under impediments are those within age, under coverture, non compos mentis, in prison, or beyond seas, who, by a saving in our laws, have time to claim and prosecute the right, after the impediments removed, in case of fines levied, &c.

IMPERATIVE, one of the moods of a verb, used when we would command, entreat, or advise.

IMPERATORIA, *masterwort,* a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The fruit is roundish, compressed in the middle, gibbous, and surrounded with a border; the petals are inflexo-

emarginated. There is but one species, viz. the ostruthium, a native of the Austrian and Stythian Alps, and other mountainous places of Italy. The plant is cultivated in gardens for the sake of its roots, which are used in medicine. The root has a flavour similar to that of angelica, and is esteemed a good sudorific. There are instances of its having cured the ague when the bark had failed. It should be dug up in winter, and a strong infusion made in wine.

IMPERFECT, something that is defective, or that wants some of the properties found in other beings of the same kind: thus mosses are called imperfect plants, because almost all the parts of fructification are wanting in them; and for the like reason is the appellation imperfect given to the fungi and submarine plants. See Moss, FUNGI, and SUBMARINE.

IMPERFECT FLOWERS, those otherwise called stamineous.

IMPERFECT NUMBERS, such whose aliquot parts, taken together, do either exceed or fall short of that whole number of which they are parts: they are either abundant or deficient.

IMPERSONAL VERB, in grammar, a verb to which the nominative of any certain person cannot be prefixed; or, as others define it, a verb destitute of the two first and primary persons.

IMPETUS, in mechanics, the force with which one body impels or strikes another.

IMPLICATION, is where the law implies something that is not declared by parties in their deeds and agreements; and when our law gives any thing to a man, it gives implicitly whatsoever is necessary for enjoying the same. 4 Black. 200.

An implied contract is such, where the terms of agreement are not expressly set forth in words, but are such as reason and justice dictate, and which therefore the law presumes that every man undertakes to perform. Id.

An implication cannot be intended by deed, unless there are apt words, but otherwise in a will. Brownl. 153.

IMPORTATION, the act of bringing goods into a country from foreign parts. It has generally been considered, that for any country to carry on a profitable trade, it is necessary that the value of the goods sent out of it should be greater than that of the articles imported: this, however, is a very erroneous axiom, unless it is understood with great limitations. All articles of merchandize, imported merely for re-exportation, and also such as are used or worked up in our own manufactures, are far from being hurtful to our commerce; and may even, in many respects, be deemed of equal profit with our own native commodities. It is therefore an excess of such importations alone as are either for mere luxury or mere necessity.

The following statement of the total value of the imports of England, in the year 1354, furnishes a curious comparison with their present magnitude.

	L.	s.	d.
1831 fine cloths, at 6*l*. per cloth, which, with the customs, come to -	11,083	12	0
397¾ hundred weight of wax, at 40*s*. per hundred weight, which, with the customs, come to - - -	815	7	5
1829½ tons of wine, at 40*s*. per ton, which, with the customs, come to	3,841	19	0
Linen-cloth, mercery, grocery, and all other wares - - - -	22,943	6	10
On which the customs were - -	285	18	3
Total - -	38,970	3	6

At this period, and for a long time after, foreigners were the principal importers of goods in that country; and as it was thought that many of them, after disposing of their merchandise here, returned with the value in money to their own country, which was deemed a serious injury, many laws were made against carrying out of the realm any gold or silver, either in coin, plate, or bullion; and merchant strangers were compelled to give security that they would lay out all the money they received for the wares they imported, in English merchandize to be exported. These injudicious restrictions have been long since done away; and excepting the prohibition of some foreign manufactures, the import trade of that country is probably as free as the regulations necessary to secure the payment of heavy duties on almost every article of trade will admit.

Total official value of the imports of Great Britain in the year 1800.

Port of London - - -	*L*18,843,172	2	10
The outports - - -	9,514,642	11	10
England - - - -	28,357,814	14	8
Scotland - - - -	2,212,790	11	8
	30,570,605	6	4

	East Indies and China.	All other parts.
In 1801	*L*5,424,441	*L*27,371,115
1802	5,794,906	25,647,412
1803	6,348,887	21,643,577
1804	5,214,621	23,986,869
1805		24,273,451

The official value of the imports of Ireland in the year 1805, was 5,982,194*l*. 19*s*. 9*d*.

IMPOSSIBLE ROOTS, in algebra. To discover how many impossible roots are contained in any proposed equation, sir I. Newton gave this rule, in his Algebra, viz: Constitute a series of fractions, whose denominators are the series of natural numbers 1, 2, 3, 4, 5, &c. continued to the number showing the index or exponent of the highest term of the equations, and their numerators the same series of numbers in the contrary order; and divide each of these fractions by that next before it, and place the resulting quotients over the intermediate terms of the equation; then under each of the intermediate terms, if its square multiplied by the fraction over it, be greater than the product of the terms on each side of it, place the sign +; but if not, the sign —; and under the first and last term place the sign +. Then will the equation have as many imaginary roots as there are changes of the underwritten signs from + to —, and from — to +. So for the equation $x^3 - 4x^2 + 4x - 6 = 0$, the series of fractions is $\frac{3}{1}, \frac{2}{2}, \frac{1}{3}$; then the second divided by the first gives $\frac{2}{6}$ or $\frac{1}{3}$, and the third divided by the second gives $\frac{1}{3}$ also; hence these quotients placed over the intermediate terms, the whole will stand thus,

$$\begin{array}{cccc} & \frac{1}{3} & \frac{1}{3} & \\ x^3 & -\ 4x^2 & +\ 4x & -\ 6. \\ + & + & - & + \end{array}$$

Now because the square of the second term multiplied by its superscribed fraction, is $\frac{16}{3}x^4$, which is greater than $4x^4$, the product of the two adjacent terms, therefore the sign + is set below the second term; and because the square of the third term multiplied by its overwritten fraction, is $\frac{16}{3}x^2$, which is less than $24x^2$, the product of the terms on each side of it, therefore the sign — is placed under that term; also the sign + is set under the first and last terms. Hence the two changes of the underwritten signs + + — +, the one from + to —, and the other from — to +, show that the given equation has two impossible roots.

When two or more terms are wanting together, under the place of the first of the deficient terms write the sign —, under the second the sign +, under the third —, and so on, always varying the signs, except that under the last of the deficient terms must always be set the sign +, when the adjacent terms on both sides of the deficient terms have contrary signs. As in the equation,

$$\begin{array}{cccccc} x^5 & +\ ax^4 & * & * & * & +\ a^5 = 0, \\ + & + & - & + & - & + \end{array}$$

which has four imaginary roots.

The author remarks, that this rule will sometimes fail of discovering all the impossible roots of an equation, for some equations may have more of such roots than can be found by this rule, though this seldom happens.

Mr. Maclaurin has given a demonstration of this rule of Newton's, together with one of his own, that will never fail. And the same has also been done by Mr. Campbell. See Phil. Trans. vols. 34 and 35.

The real and imaginary roots of equations may be found from the method of fluxions, applied to the doctrine of maxima and minima; that is, to find such a value of x in an equation, expressing the nature of a curve, made equal to y, an abscissa which corresponds to the greatest and least ordinate. But when the equation is above three dimensions, the computation is very laborious. See Stirling's Treatise on the Lines of the third Order.

IMPOSTHUME, the same with abscess. See Surgery.

IMPRESSING men. The power of impressing seamen for the sea service, by the king's commission, has been a matter of some dispute, and submitted to with great reluctance, though it has very learnedly been argued by sir Michael Foster, that the practice of impressing, and granting power to the admiralty for that purpose, is of very ancient date, and has been continued by a regular series of precedents to the present time, whence he concludes it to be part of the common law. The difficulty arises hence, that no statute has expressly declared this power to be in the crown, though many of them very strongly imply it. The stat. 2 R. II. c. 4. speaks of mariners being arrested and retained for the king's service, as of a thing well known and practised without dispute, and provides a remedy against the running away.

By stat. 2 and 3 P. and M. c. 16, if any waterman who uses the river Thames, shall hide himself during the execution of any commission for pressing for his majesty's service, he is liable to heavy penalties. By stat. 5 Eliz. c. 6. no fisherman shall be taken by the queen's commission to serve as a mariner; but the commission shall be first brought to two justices of the peace, inhabiting near the sea-coast where the mariners are to be taken, to the intent that the justices may choose out and return such a number of able bodied men as in the commission are contained to serve her majesty. And by stat. 7 and 8 W. c. 21.; 2 Anne, c. 6.; 4 and 5 Anne, c. 19.; 13 Geo. II. c. 17; especial protections are allowed to seamen in particular circumstances, to prevent them from being impressed. All which certainly imply a power of impressing to reside somewhere; and if any where, it must, from the spirit of their constitution, as well as from the frequent mention of the king's commission, reside in the crown alone. 1 Black. 419.

IMPRISONMENT, is the restraint of a man's liberty under the custody of another, and extends not only to a goal, but a house, stocks, or where a man is held in the street, or any other place; for, in all these cases, the party so restrained is said to be a prisoner so long as he has not his liberty freely to go about his business as at other times.

None shall be imprisoned but by the lawful judgment of his peers, or by the law of the land. Magna Charta.

Imprisonment, *false*. To constitute the injury of false imprisonment, two points are necessary: the detention of the person, and the unlawfulness of such detention. Every confinement of the person is imprisonment, whether it is in a common prison, or in a private house, or in the stocks, or even by forcibly detaining one in the streets. 2 Inst. 589.

By Magna Charta, no freeman shall be taken and imprisoned, but by the lawful judgment of his equals, or by the law of the land: and by the petition of right, 3 C. I. no freeman shall be imprisoned or detained without cause shown, to which he may make answer according to law. And by the 16 C. I. c. 10. if any person is restrained of his liberty, he may, upon application by his counsel, have a writ of habeas corpus, to bring him before the court of king's bench or common pleas, who shall determine whether the cause of his commitment is just, and thereupon do as to justice appertains.

For false imprisonment the law has not only decreed a punishment by fine and imprisonment, as a heinous public crime, but has also given a private reparation to the party by action at law, wherein he shall recover damages for the loss of his time and liberty. 3 Black. 127.

IMPROPER fractions. See Arithmetic, and Algebra.

IMPROPRIATION, is properly so called when a benefice ecclesiastical is in the hands of a layman; and appropriation when in the hands of a bishop, college, or religious house, though sometimes these terms are confounded. It is said there are 3845 impropriations in England.

IMPULSE, or Impulsive Force, the same with impetus. See Mechanics.

INARCHING, in gardening. See Grafting.

INCA, or Ynca, a name given by the natives of Peru to their kings, and the princess of the blood.

INCAPACITY, in the canon law, is of two kinds:

1. The want of a dispensation for age in a minor, for legitimation in a bastard, and the like: this renders the provision of a benefice void in its original. 2. Crimes and heinous offences, which annul provisions at first valid.

INCH, a well-known measure of length, being the twelfth part of a foot, and equal to three barleycorns in length.

INCIDENCE, in mechanics, denotes the direction in which one body strikes on another. See MECHANICS, and OPTICS,

INCLINATION, is a word frequently used by mathematicians, and signifies the mutual approach, tendency, or leaning, of two lines or two planes towards each other, so as to make an angle.

Inclination of a right line to a plane, is the acute angle which that line makes with another right line drawn in the plane through the point where the inclined line intersects it, and through the point where it is also cut by a perpendicular drawn from any point of the inclined plane.

Inclination of the axis of the earth, is the angle which it makes with the plane of the ecliptic; or the angle contained between the planes of the equator and ecliptic.

Inclination of a planet, is an arch of the circle of inclination comprehended between the ecliptic and the plane of a planet in its orbit. See ASTRONOMY.

The greatest inclination of Saturn, according to Kepler, is 2° 32′; of Jupiter, 1° 20′; of Mars, 1° 50′ 30″; of Venus, 3° 22′; of Mercury, 6° 54′. According to de la Hire, the greatest inclination of Saturn is 2° 33′ 30″; of Jupiter, 1° 19′ 20″; of Mars, 1° 51′; of Venus, 3° 25′ 5″; of Mercury, 6° 52′.

Inclination of a plane, in dialling, is the arch of a vertical circle, perpendicular both to the plane and the horizon, and intercepted between them. To find this, let AB (see Plate LXXII. Misc. fig. 135) be a plane inclined to the horizon HR; apply to the plane AB a quadrant DCF, so that the plummet CE may cut off any number of degrees on the limb, as EF: then the arch DE is the measure of the angle of inclination ABH; for draw BG perpendicular to HR, then because CE is parallel to BG, the angle ECF is equal to CBG; but DCF is equal to GBH, being both right angles, therefore the angle DCF — ECF, is equal to the angle GBH — CBG; that is, DCE is equal ABH.

INCLINED PLANE, in mechanics, one that makes an oblique angle with the horizon. See MECHANICS.

INCOMMENSURABLE, a term in geometry, used where two lines, when compared to each other, have no common measure, how small soever, that will exactly measure them both. And in general, two quantities are said to be incommensurable, when no third quantity can be found that is an aliquot part of both.

Such are the diagonal and side of a square; for though each of those lines has infinite aliquot parts, as the half, the third, &c. yet not any part of the one, be it ever so little, can possibly measure the other, as is demonstrated by Euclid.

INCOMMENSURABLE NUMBERS, are such as have no common divisor that will divide them both equally.

INCORRUPTIBILES, or INCORRUPTICOLÆ, in church history, heretics which had their original at Alexandria, in the time of the emperor Justinian. Their distinguishing tenet was, that the body of Jesus Christ was incorruptible from his conception, by which they meant that after and from the time he was formed in the womb of his holy mother, he was not susceptible of any change or alteration, not even of any natural and innocent passions, as hunger, thirst, &c. so that he ate without any occasion before his death, as well as after his resurrection.

INCUBUS, or NIGHT-MARE. See MEDICINE.

INCUMBENT, a clerk or minister who is resident on his benefice: he is called incumbent, because he does, or at least ought, to bend his whole study to discharge the cure of his church.

INCURVATION *of the rays of light*, their bending out of a rectilinear or straight course, occasioned by refraction.

INDEMNITY, in law, the saving harmless; or, a writing to secure one from all damage and danger that may ensue from any act. An indemnity in regard to estates is called a warranty.

INDENTED, in heraldry, is when the outline of an ordinary is notched like the teeth of a saw.

INDENTED-LINE, in fortification, the same with what the French engineers call redent; being a trench and parapet running out and in, like the teeth of a saw, and much used in irregular fortification.

INDENTURE, is a writing containing a conveyance between two or more, indented or cut unevenly, or in and out, on the top or side, answerable to another writing that likewise comprehends the same words. Formerly when deeds were more concise than at present, it was usual to write both parts on the same piece of parchment, with some words or letters written between them, through which the parchment was cut, either in a straight or indented line, in such a manner as to leave half the word on one part, and half on the other: and this custom is still preserved in making out the indentures of a fine. But at last, indenting only has come into use without cutting through any letters at all; and it seems at present to serve for little other purpose than to give name to the species of the deed. 2 Black. 294.

INDEPENDENTS, a sect of protestants in England and Holland, so called from their independency on other churches, and their maintaining that each church or congregation has sufficient power to act and perform every thing relating to religious government within itself, and is no way subject or accountable to other churches or their deputies.

The present independents differ from the presbyterians only in their church government, in being generally more attached to the doctrines distinguished by the term orthodoxy, such as original sin, election, reprobation, &c. and in administering the Lord's supper at the close of the afternoon's service. The several sects of baptists are all independents with respect to church-government; and, like them, administer the Lord's supper in the evening, whereas the presbyterians administer it after the forenoon's service.

INDETERMINATE PROBLEM, in algebra, one which is capable of an indefinite number of solutions.

INDEX, in arithmetic and algebra, shows to what power any quantity is involved, and is otherwise called exponent.

INDEX *of a logarithm*, that which shows of how many

places the absolute number belonging to a logarithm consists, and of what nature it is, whether an integer or fraction. Thus, in this logarithm 2.523421, the number 2 standing on the left hand of the point is called the index; because it shows that the absolute number, answering to the above logarithm, consists of three places: for the number is always one more than the index. If the absolute number is a fraction, then the index of the logarithm has a negative sign marked thus 2.523421.

INDEX *of a globe*, the little style or gnomon, which being fixed on the pole of the globe, and turning round with it, points out the hours upon the hour-circle. See GLOBE.

INDIAN BERRY, in commerce, &c. See COCULUS.

INDICATIVE, in grammar, the first mood or manner of conjugating a verb, by which we simply affirm, deny, or ask something; as, *amant*, they love; *non amant*, they do not love; *amantne*, do they love?

INDICTION, in chronology, a cycle of 15 years. The Roman or papal indiction, which is that used in the pope's bulls, begins on the 1st of January; and by it the popes have dated their acts ever since Charlemagne made them sovereigns. But besides this, there are other two kinds of indiction mentioned by authors, viz. that of Constantinople, beginning on the 1st of September; and the imperial or Cæsarian indication, which commenced on the 14th of September. See CYCLE.

INDICTION is also used for the convoking an ecclesiastical council or assembly.

INDICTMENT, is a written accusation of one or more persons of a crime or misdemeanor, preferred to, and presented on oath by, a grand jury. 4 Black. 302.

An indictment may be found on the oath of one witness only, unless it is for high treason, which requires two witnesses; and unless in any instance it is otherwise specially directed by acts of parliament. 2 Haw.

The sheriff of every county is bound to return to every session of the peace, and every commission of oyer and terminer, and of general goal-delivery, 24 good and lawful men, of the county, some out of every hundred, to inquire, present, do, and execute, all those things which on the part of our lord the king, shall then and there be commanded therein. As many as appear upon this pannel are sworn of the grand jury, to the amount of twelve at the least, and not more than twenty-three, that twelve may be a majority. This grand jury is previously instructed in the articles of their inquiry, by a charge from the judge on the bench. They then withdraw from the court to sit and receive indictments, which are preferred to them in the name of the king, but at the suit of any private prosecutor; and they are only to hear evidence on behalf of the prosecution: for the finding an indictment is only in the nature of an inquiry or accusation, which is afterwards to be tried or determined; and the grand jury are only to inquire upon their oaths whether there is sufficient cause to call upon the party to answer it.

It seems generally agreed, that the grand jury may not find part of an indictment true and part false; but must either find a true bill or ignoramus for the whole; and if they take upon them to find it specially or conditionally, or to be true for part only and not for the rest, the whole is void, and the party cannot be tried upon it, but ought to be indicted anew. 2 Haw. 210.

All capital crimes whatever, and all kinds of inferior crimes which are of a public nature, as misprisions, contempts, disturbances of the peace, oppressions, and all other misdemeanors whatever of a public evil example against the common law, may be indicted, but no injuries of a private nature, unless they in some degree concern the king. And generally where a statute prohibits a matter of public grievance to the liberties and security of a subject, or commands a matter of public convenience, as the repairing of the common streets of the town, &c. every disobedience of such statute is punishable, not only at the suit of the party grieved, but also by way of indictment, for contempt of the statute, unless such method of proceeding shall manifestly appear to be excluded by it. Yet if the party offending has been fined in an action brought by the party (as it is said he may in every action for doing a thing prohibited by statute), such fine is a good bar to the indictment, because by the fine the end of the statute is satisfied; otherwise he would be liable to a second fine for the same offence. 2 Inst. 55.

If several offenders commit the same offence, though in law they are several offences in relation to the several offenders, yet they may be joined in one indictment; as if several commit a robbery, or burglary, or murder. 2 H. H. 173.

No indictment for high treason, or misprision thereof (except indictments for counterfeiting the king's coin, seal, sign, or signet), nor any process or return thereupon, shall be quashed for mis-reciting, mis-spelling, false or improper Latin, unless exception concerning the same is taken and made in the respective court where the trial shall be, by the prisoner or his counsel assigned, before any evidence given in open court on such indictment; nor shall any such mis-reciting, mis-spelling, false or improper Latin, after conviction on such indictment, be any cause or stay, or arrest of judgment; but nevertheless, any judgment on such indictment shall be liable to be reversed on writ of error as formerly.

An indictment accusing a man in general terms, without ascertaining the particular fact laid to his charge, is insufficient; for no one can know what defence to make to a charge which is uncertain, nor can plead it in bar or abatement of a subsequent prosecution; neither can it appear that the facts given in evidence against a defendant on such a general accusation, are the same of which the indictors have accused him; nor can it judicially appear to the court what punishment is proper for an offence so loosely expressed. 2 Haw. 266.

It is therefore best to lay all the facts in the indictment as near to the truth as possible; and not to say, in an indictment for a small assault (for instance) wherein the person assaulted received little or no bodily hurt, that such a one, with swords, staves, and pistols, beat, bruised, and wounded him, so that his life was greatly despaired of; not to say in an indictment for a highway being obstructed, that the king's subjects cannot go thereon without manifest danger of their lives, and the like: which kind of words not being necessary, may stagger an honest man upon his oath to find the fact as so laid.

No indictment can be good without expressly showing some place wherein the offence was committed, which must appear to have been within jurisdiction of the court. 2 Haw. 236.

There are several emphatical words which the laws has

appropriated for the description of an offence, which no circumlocution will supply; as *feloniously*, in the indictment of any felony; *burglariously*, in an indictment of burglary, and the like. 2 H. H. 184.

An indictment on the black act for shooting at any person must charge that the offence was done wilfully and maliciously.

By 10 and 11 W. c. 23, it is enacted, that no clerk of assize, clerk of the peace, or other person, shall take any money of any person bound over to give evidence against a traitor or felon for the discharge of his recognizance, nor take more than 2*s*. for drawing any bill of indictment against any such felon, on pain of 5*l*. to the party grieved, with full costs. And if he shall draw a defective bill, he shall draw a new one gratis on the like penalty.

With respect to drawing indictments for other misdemeanors, not being treason or felony, no fee is limited by the statute; the same, therefore, depends on the custom and ancient usage.

Every person charged with any felony or other crime, who shall on his trial be acquitted, or against whom no indictment shall be found by the grand jury, or who shall be discharged by proclamation for want of prosecution, shall be immediately set at large in open court, without payment of any fee to the sheriff or gaoler; but in lieu thereof, the treasurer, on a certificate signed by one of the judges or justices before whom such prisoner shall have been discharged, shall pay out of the general rate of the county or district, such sum as has been usually paid, not exceeding 13*s*. 4*d*.

But an action cannot be brought by the person acquitted against the prosecutor of the indictment, without obtaining a copy of the record of his indictment and acquittal; which in prosecutions for felony it is not usual to grant, if there is the least probable cause to found such prosecution upon. For it would be a very great discouragement to the public justice of the kingdom, if prosecutors who had a tolerable ground of suspicion were liable to be sued at law whenever their indictments miscarried. But an action on the case for a malicious prosecution may be founded on such an indictment whereon no acquittal can be, as if it is rejected by the grand jury, or is coram non judice, or is insufficiently drawn; for it is not the danger of the plaintiff, but the scandal, vexation, and expense, upon which this action is founded. However, any probable cause for preferring it is sufficient to justify the defendant, provided it does not appear that the prosecution was malicious. 3 Black. 126.

INDIGOFERA, *the indigo plant*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is patent: the carina of the corolla furnished with a subulated patulous spur on each side; the legumen is linear. There are 35 species, the most remarkable of which is the tinctoria, a native of the warm parts of Asia, Africa, and America. This plant requires a rich soil, well tilled, and not too dry. The seed of it, which as to figure and colour, resembles gunpowder, is sown in little furrows that are about the breadth of the hoe, two or three inches deep, at a foot distance from each other, and in as straight a line as possible. Continual attention is required to pluck up the weeds, which would soon choke the plant. Though it may be sown in all seasons, the spring is commonly preferred. Moisture causes this plant to shoot above the surface in three or four days. It is ripe at the end of two months. When it begins to flower, it is cut with pruning-knives; and cut again at the end of every six weeks, if the weather is a little rainy. It lasts about two years, after which term it degenerates: it is then plucked up, and planted afresh. As this plant soon exhausts the soil, because it does not absorb a sufficient quantity of air and dew to moisten the earth, it is of advantage to the planter to have a vast space which may remain covered with trees, till it becomes necessary to fell them in order to make room for the indigo.

The valuable dye-stuff called indigo bears some faint resemblance to starch; but its properties are sufficiently peculiar to distinguish it from all other substances, and its importance entitles it to a distinguished place among vegetable principles. It is commonly procured by the following process:

When the plant has been cut down, it is placed in strata in a large wooden vessel, and covered with water. In this situation it cannot remain long in these warm climates without undergoing some change. Putrefaction, accordingly, very soon commences, or rather a kind of fermentation, which goes on best at the temperature of 80°. The water soon becomes opaque, and assumes a green colour; a smell resembling that of volatile alkali is exhaled, and bubbles of carbonic acid are emitted. When the fermentation has continued long enough, which is judged of by the paleness of the leaves, and which requires from six to twenty-four hours according to the temperature of the air and the state of the plant, the liquid is decanted off the plants into large flat vessels, where it is constantly agitated till blue floculi begin to make their appearance; water is now poured in, which causes the blue flakes to precipitate. The yellow liquid is decanted off, and the blue sediment poured into linen bags. When the water has drained from it sufficiently, it is formed into small lumps, and dried in the shade. In that state it is sold under the name of indigo.

The leaves of the indigofera yield a green infusion to hot water, and a green powder may be precipitated from it; but unless a fermentation has taken place, neither the colour nor properties of it have any resemblance to indigo.

Indigo may be obtained from the nerium tinctorium, and the isatis tinctoria or woad; a plant commonly enough cultivated in Britain, and even found wild in England. When arrived at maturity, this plant is cut down, washed, dried hastily in the sun, ground in a mill, placed in heaps, and allowed to ferment for a fortnight. It is then well mixed, and made up into balls, which are piled upon each other, and exposed to the wind and sun. In this state they become hot, and exhale a putrid ammoniacal smell. The fermentation is promoted, if necessary, by sprinkling the balls with water. When it has continued for a sufficient time, the woad is allowed to fall to a coarse powder; in which state it is sold as a dye-stuff. By treating woad nearly in the same manner with the indigofera, indigo has been obtained from it by different chemists.

Indigo is a fine light friable substance, of a deep-blue-

colour. Its texture is very compact, and the shade of its surface varies according to the manner in which it has been prepared. The principal tints are copper, violet, and blue; the lightest indigo is the best: but it is always more or less mixed with foreign substances, partly owing, doubtless, to the carelessness of the preparation, and partly to the bodies which the plant containing indigo yields to water. From the analysis of Bergman, to whom we are indebted for one of the most complete treatises on the properties of indigo which has yet appeared, the purest indigo which he could procure, was composed of the following constituents:

47	pure indigo
12	gum
6	resin
22	earth
13	oxide of iron
100.	

The earth consisted of,

10.2	barytes
10.0	lime
1.8	silica
22.0	

But in all probability the earth differs in different specimens; for Proust found magnesia in considerable quantity in the specimens which he examined. The forty-seven parts of blue pigment are alone entitled to the name of indigo; and to them therefore we shall confine our attention.

Indigo is a soft powder, of a deep blue, without either taste or smell. It undergoes no change, though kept exposed to the air. Water does not dissolve any part of it, nor produce any change upon it. Bergman, however, found that indigo, when kept long under water, underwent a kind of putrefaction, or at least exhaled a fetid odour. When heat is applied to indigo, it emits a bluish red smoke, and at last burns away with a very faint white flame, leaving behind it the earthy parts in the state of ashes.

Neither oxygen nor the simple combustibles have any effect upon indigo, except it is in a state of solution; and the same remark applies to the metallic bodies.

The fixed alkaline solutions have no action on indigo, except it is newly precipitated from a state of solution. In that case they dissolve it with facility. The solution has at first a green colour, which gradually disappears, and the natural colour of the indigo cannot again be restored. Hence we see that the alkalies when concentrated decompose indigo. Pure liquid ammonia acts in the same way. Even carbonat of ammonia dissolves precipitated indigo, and destroys its colour; but the fixed alkaline carbonats have no such effect.

Lime-water has scarcely any effect upon indigo in its usual state; but it readily dissolves precipitated indigo. The solution is at first green, but becomes gradually yellow. When the solution is exposed to the air, a slight green colour returns, as happens to the solution of indigo in ammonia; but it soon disappears. The effect of the other alkaline earths upon indigo has not hitherto been tried; but it cannot be doubted that they would act nearly as lime-water, but with more energy. The other earths seem to have but little action on indigo in any state.

The action of the acids upon indigo has been examined with most attention, and it certainly exhibits the most important phenomena.

When diluted sulphuric acid is digested over indigo, it produces no effect, except that of dissolving the impurities; but concentrated sulphuric acid dissolves it readily. One part of indigo, when mixed with eight parts of sulphuric acid, evolves heat, and is dissolved in about 24 hours. According to Haussman, some sulphurous acid and hydrogen gas are evolved during the solution. If so, we are to ascribe them to the mucilage and resin, which are doubtless destroyed by the action of the concentrated acid. The solution of indigo is well known in this country by the name of liquid blue. Bancroft calls it sulphat of indigo. While concentrated it is opaque and black; but when diluted it assumes a fine deep-blue colour; and its intensity is such, that a single drop of the concentrated sulphat is sufficient to give a blue colour to many pounds of water. Bergman ascertained the effect of different re-agents on this solution with great precision. His experiments threw light, not only on the properties of indigo, but upon the phenomena that take place when it is used as a dye-stuff. The following is the sum of these experiments:

Dropt into sulphurous acid. Colour at first blue, then green, and very speedily destroyed.—In weak tartaric acid. Becomes gradually green, and in 144 hours had assumed a very pale yellow colour. Colour not restored by alkalies.—In vinegar. Becomes green, and in four weeks the colour disappeared.—In weak potass. Becomes green, and then colourless.—In weak carbonat of potass. The same changes, but more slowly. If the solution is very weak, the colour of the indigo is not destroyed.—In ammonia and its carbonat. Colour becomes green, and then disappears.—In a weak solution of sulphat of soda. Colour after some weeks becomes green.—In tartrat of potass. Became green, and then colourless.—In a solution of sugar. Became green, and at last yellowish.—In sulphat of iron.—Colour became green, and in three weeks disappeared.—In the sulphurets. Colour destroyed in a few hours.—Realgar, white oxide of arsenic, and orpiment, produced no change.—Black oxide of manganese destroyed the colour completely.—In the infusion of madder. Colour became green, and at last yellow.—In the infusion of woad, the same changes, but more speedily.

From these experiments it is obvious that all those substances which have a very strong affinity for oxygen give a green colour to indigo, and at last destroy it. Hence it is extremely probable that indigo becomes green by giving out oxygen. Of course it owes its blue colour to that principle. This theory was first suggested by Mr. Haussman, and still farther confirmed by Berthollet. Now it is only when green that it is in a state capable of being held in solution by lime, alkalies, &c. in which state it is applied as a dye to cloth. The cloth when dipt into the vat containing it thus dissolved, combines with it, and the blue colour is restored by exposure to the atmosphere. It may be restored equally by plunging the cloth into oxy-muriatic acid. Hence the resto-

ration cannot but be ascribed to oxygen. Hence, then, the reason that sulphurous acid, the vegetable acids, sulphat of iron, give sulphat of indigo a green colour.

From these experiments we see also that the colour of indigo is destroyed by the addition of those substances which part with oxygen very readily, as the black oxide of manganese. In that case the indigo is destroyed, for its colour cannot be again restored.

Nitric acid attacks indigo with great violence, the evolution of abundance of heat, and nitrous gas. When of the specific gravity 1.52, it even sets fire to indigo. When the acid is diluted the indigo becomes brown, and crystals make their appearance, doubtless consisting of oxalic acid. What remains behind is a brown viscid substance of a very bitter taste, probably analogous to the yellow bitter principle of Welter.

Muriatic acid does not act upon indigo in its common state, but it readily dissolves indigo precipitated from the sulphat, and forms a blue coloured solution. The same phenomena are exhibited by the prosphoric, acetic, tartaric acids, and probably by all, except the acid supporters.

Oxymuriatic acid destroys the colour of indigo as readily as nitric acid, and obviously for the same reason.

Indigo is not acted upon by alcohol, ether, nor oils. The two first solvents, indeed, acquire a yellow colour when digested on common indigo by dissolving its resin.

When indigo is mixed up with bran, woad, and other similar substances, which readily undergo fermentation, it assumes a green colour during the fermentation, and is then easily dissolved by lime or potass. It is by this process that it is usually rendered proper for dyeing.

When indigo is distilled, it yields products different from any other vegetable substance, if the accuracy of Bergman, who alone has made the experiment, is to be trusted. He distilled 576 grains in a small retort connected with a pneumatic apparatus. He obtained the following products:

19	grains	carbonic acid gas
173	——	of a yellow acid liquid, containing ammonia
53	——	oil
331	——	charcoal
576.		

INDIVISIBLES, in geometry, the elements or principles into which any body or figure may be ultimately resolved; which elements are supposed infinitely small: thus a line may be said to consist of points, a surface of parallel lines, and a solid of parallel and similar surfaces; and then, because each of these elements is supposed indivisible, if in any figure a line be drawn through the elements perpendicularly, the number of points in that line will be the same as the number of the elements; whence we may see that a parallelogram, prism, or cylinder, is resolvable into elements or indivisibles, all equal to each other, parallel and like to the base; a triangle into lines parallel to the base, but decreasing in arithmetical proportion; and so are the circles which constitute the parabolic conoid, and those which constitute the plane of a circle, or surface of an isosceles cone.

A cylinder may be resolved into cylindrical curve surfaces, having all the same height, and continually decreasing inwards, as the circles of the base do on which they insist.

The method of indivisibles is only the ancient method of exhaustions, a little disguished and contracted. It is found of great use in shortening mathematical demonstrations, of which take the following instance in the famous proposition of Archimedes, viz. that a sphere is two-thirds of a cylinder circumscribing it.

Suppose a cylinder, a hemisphere, and an inverted cone (Plate LXXII. Miscel. fig. 133) to have the same base altitude, and to be cut by infinite planes all parallel to the base, of which dg is one. It is plain the square of dh will be every where equal to the square of kc (the radius of the sphere); and consequently, since circles are to one another as the squares of the radii, all the circles of the hemisphere will be equal to all those of the cylinder, deducting thence all those of the cone: wherefore the cylinder, deducting the cone, is equal to the hemisphere; but it is known that the cone is one-third of the cylinder, and consequently the sphere must be two-thirds of it.

INDORSEMENT, in law, any thing written on the back of a deed, as a receipt for money received. See Bills of Exchange.

INDUCEMENT, in law, what is alledged as a motive or incitement to a thing, and is used specially in many cases; as, there is an inducement in actions, to a traverse in pleadings, a fact or offence committed, &c.

Inducements to actions need not to have so much certainty as in other cases: a general indebitatus is not sufficient where it is the ground of the action; but where it is the inducement to the action, as in consideration of forbearing a debt till such a day (for that the parties are agreed upon the debt), this being but a collateral promise, is good without showing how due. 2 Mod. 70. An inducement to a traverse must be such matter as is good and justifiable in law. There is an inducement to a justification when what is alledged against it is not the substance of the plea. Moor. 847.

INDUCTION, in law, is the giving a clerk instituted to a benefice the actual possession of the temporalities thereof, in the nature of livery of seisin. It is performed by a mandate from the bishop to the archdeacon, who commonly issues out a precept to some other clergyman to perform it for them; which being done, the clergyman who inducts him indorses a certificate of his induction on the archdeacon's mandate, and they who were present testify the same under their hands, and by this the person inducted is in full and complete possession of all the temporalities of his church.

INDULT, in the church of Rome, the power of presenting to benefices granted to certain persons by the pope. Of this kind is the indult of kings and sovereign princes, in the Romish communion, and that of the parliament of Paris granted by several popes. By the concordat for the abolition of the pragmatic sanction, made between Francis I. and Leo X. in 1516, the French king had the power of nominating to bishoprics, and other consistorial benefices, within his realm. At the same time, by a particular bull, the pope granted him the privilege of nominating to the churches of Brittany and Provence.

INERTIA of matter, in philosophy, is defined by

sir Isaac Newton to be a passive principle by which bodies persist in their motion or rest, receive motion in proportion to the force impressing it, and resist as much as they are resisted. It is also defined by the same author to be a power implanted in all matter, whereby it resists any change endeavoured to be made in its state. See MECHANICS.

INFAMY, which extends to forgery, perjury, gross cheats, &c. disables a man to be a witness or a juror; but a pardon of crimes restores a person's credit to make him a good evidence. 2 Haw. 432.

INFANCY, *management and diseases of.* We have been induced to treat of those disorders which are peculiar to infancy separately from other affections, partly by the difference of character which such ailments assume from those of the adult periods of life, and partly by the opportunity the subject will afford of introducing some preliminary observations on the management of infants; observations which we shall endeavour to make familiar and intelligible to the heads of families, or those engaged in conducting the human frame through its more tender and dependant states of existence.

It would be altogether superfluous to urge the importance of this subject. It has been calculated that more than a fourth part of the human race die in the first year after birth; and we have nearly the same evidence that this remarkable mortality originates not in the unchangeable dispositions of nature, but principally from erroneous and perverted management!

In the first division of this article we propose, therefore, to suggest a few hints respecting infantile diet; the regulation of temperature, or external heat; clothing; air, and exercise.

PART I.

SECT. I.—*Diet of infants.*

In the proper nourishment of children we are faithfully instructed by the almost unerring counsels of nature. Where mothers are capable of suckling their offspring, this ought, in no instance, to be omitted: it is, indeed, equally a cause of astonishment and regret that such an obvious and important principle could at any time be neglected or questioned. "See the infant (says a modern writer, while addressing himself to mothers) nourished by your fluids, and brought to a certain degree of perfection while yet in the womb. See him separated from it, and then see his nourishment flowing in another channel. See the secretion and preparation of the milk, the increasing size of the breast, and the formation of the nipples. Behold the economy of the infant himself; see him instinctively taught to search for the breast, and to suck the breast; to draw his nourishment from a new source, yet still from your body, and from your fluids. Did you see this connection sufficiently, you would neither give him over to the suckling of another woman, nor would you feed him with any other substance than your own milk." Dr. Herdman on Infancy.

Dr. Buchan gives it as his opinion, that not one in a hundred of those children survives who are abandoned by their mothers, and committed to the charge of foster-parents in the earliest stages of life; and although we may deem this statement in some measure exaggerated, the reflection of its approach to truth ought to be a sufficient incitement for the appointed and professed guardians of the health and well-being of society to enter a severe and unbiassed protest against the custom to which we now refer.

For the first two or three months the nutriment of the infant ought to be received entirely from the breast of its mother. During the whole of this time its wants are almost confined to nourishment and sleep. It is, however, to be confessed that there are some, although but comparatively few, instances of inability on the part of the parent to furnish milk in due quantity or suitable quality to the requisitions of her offspring. "To the puny progeny of a puny consumptively-disposed mother I would forbid (says Dr. Beddoes) the mother's breast." Now, although we are inclined to suppose that the author just quoted has admitted too much in favour of what is termed rearing by hand (for capacity of bearing is commonly connected with a capacity of nursing children), yet, where circumstances necessarily deprive the child of its regular and more salutary nutriment, it becomes a question of moment, What is to be substituted in its place? Not by any means what the generality of hired attendants direct. As soon as an infant by its cries denotes hunger, the nurse has, for the most part, instant recourse to a mixture of bread and water (pap), which is perhaps spiced, or qualified with a little brandy. To attempt the union of oil and water would be scarcely less incongruous: it is not hazarding any thing to assert, that the major part of infantile ailments are to be attributed to the heterogeneous compounds that are early given to children; and the spicy or spirituous ingredients which are added, in order to force an artificial digestion. The necessity of the latter bears decided evidence against the propriety of the former. In no period of life, during health, ought food to be of such a quality as to require the assistance of condiments or spirits; which last are especially injurious to the assimilating organs of a new-born infant.

About half a tea-cupful of cow's milk, gently warmed, is the only food that ought to be given to a child at its birth, after which it will frequently sleep for ten hours; a symptom which, although often alarming to the obtrusive ignorance of nurses, is to be regarded as a demonstration of the proper nature of the food that has been given, and an indication of future health.

To this plan it is sometimes necessary to have recouse, even when it is the intention of the mother to suckle her child, as women who have had many children frequently have no proper secretion of milk until after the second or third day from delivery.

Before quitting this part of the subject it is proper to observe, that the custom of immediately pouring down purgatives, as if to prove to the little stranger that it has arrived in a world of physic and of evils, is, although very generally adopted, highly injudicious. The bowels do not, in general, require to be thus artificially cleansed.

With respect to the quantity and times of administering food, mothers and nurses are accustomed to err. Nothing can be more improper than to suckle or feed an infant two or three times in the course of an hour. A child judiciously regulated does not demand nourishment, even during the first months, more than once in three or

four hours; as it advances it requires feeding even less frequently, and less sleep during the day.

It has already been stated that, with the exceptions pointed out, the mother's breast ought, at least during the first two or three months, to be the sole repository and entire source of infantile nutriment. If the child is brought up by hand, cow's milk gently warmed is all the food that will be necessary for the first four or five months. After these times milk may be alternated, not by moist bread, biscuit, cakes, sugar, panadas, and gruel, but by ground rice or flour well baked; the gravy of boiled meat, which last will generally be taken with avidity; small quantities of beef-tea, or veal-jelly, and other substances of the like nature; still avoiding, unless during the actual existence of disease, and under professional direction, every article in the long list of fermented, fermenting, spicy, and spirituous materials; the withholding of which, however it may offend and alarm the nurse, will be of incalculable benefit to the child.

The time of weaning must be regulated entirely by circumstances. The process should not be abrupt, but gradual. It is very seldom advisable to refuse the breast entirely before the ninth or tenth month.

We have particularly insisted on the necessity of excluding those substances from the diet of infants which are disposed to ferment, or turn sour. A general acquaintance with the laws which regulate the existence and decomposition of such substances may be acquired with less labour than would be requisite to retain in the memory, without the aid of some connecting principle, all the individual articles which are prescribed or admitted as part of the diet in childhood and youth; and in consequence of such pleasing and easy acquisition, we should find knowledge and humanity joining issue in the joyous task of averting the artificial evils which ignorance and error have made to attach to the extremely susceptible, though not naturally unhealthy, state of the primary periods of existence. Whence does the perversity of nurses respecting the treatment of children arise? Solely from ignorance. Were they convinced that the plans which are adopted prove ultimately subversive of their intended object, they would readily consent to abandon them. "Obedience will always be more cheerful and steady after a reasonable explanation." "I have heard a variety of mothers (says Dr. Beddoes) complain that sugar, biscuit, and cakes, disagreed in the most evident manner; and yet that it was impossible, by any injunctions, to prevent the one from being made a part of the food, and the other (sugar) from being given to stop the hiccups, or produce a sensation that should suspend crying for a moment. Now it is well known that perpetually recurring complaints in the stomach and bowels arise from mere sourness; and the parties, by whose mistaken kindness, or by whose delicacy of ear they are occasioned, are perfectly informed so far. It remains only to carry their knowledge a step farther. Respecting the juice of the sugar-cane, it is a very striking particular, that the poorest sort will scarcely keep a quarter of an hour in the receiver without turning sour. This can only be *told*. The acescent nature of bread, of sugar, and of the various compositions into which bread and sugar enter, may be *shown*. For this purpose it is only necessary that a solution of sugar and water should be made into vinegar. In like manner bread and sweet cake should be placed in a heat nearly equal to that of the human body, and the servant be put to taste the infusion when it becomes acid. By an address suited to the object in view, there will surely be small difficulty in giving these simple experiments all the effect that can be desired.

"I shall very contentedly allow the childless wit to laugh at me for the whimsical idea of tutoring nursemaids in chemistry. I have a balm at hand for any wound the shafts or ridicule may inflict. Considerate parents will avail themselves of so practicable an expedient, and many little sufferers will escape the consequences of an improper regimen. And these are probably (the author might have said *certainly*) far more serious, even in respect to the future than the present. For it clearly results from a contemplation of the manner in which human feelings and ideas gain their connection, that frequent discomposure of the stomach in the morning of life may be instrumental in overcasting its meridian and its close with a cloud of misery, such as neither skill nor fortune can disperse." [Beddoes' Hygeia]. For further information on the subject of diet, consult the article MATERIA MEDICA, section Dietetics.

SEC. II.—*Of temperature, including remarks on the clothing, and likewise on the washing or bathing, of infants.*

The remarkable success with which the subject of animal temperature has been recently investigated, and the application of facts, deduced from a developement of its laws, to the living system, both in its healthy and disordered state, constitute perhaps the most material improvements in modern physiology and medical practice.

Respecting the generation and adjustment of animal heat, is it not the business of this article to inquire (see PHYSIOLOGY, and MEDICINE:) our present plan extends no farther than the statement of a few practical rules on the subject of heat and cold, absolutely necessary to be attended to by all who undertake the guardianship of infancy and childhood: "for the management of temperature is of high importance in the treatment of the infant. It runs through, and is connected with, every part of his general treatment. It is to be considered in his dress, in his covering while asleep, in his bathing or washing, in his treatment in the house as well as out of it, in his air and exercise. In short, with a competent knowledge of the management of temperature, a nurse can scarcely go wrong in any part of the general treatment of an infant." [Herdman.] It must be obvious to every one that the infant at birth necessarily undergoes a sudden and material alteration in the temperature of the medium by which, without clothing, it is surrounded. The effects which would result otherwise from this remarkable change, with respect to external warmth, are in some measure obviated by the immediate commencement of respiration. This, however, is not sufficient of itself to supply the defect of external heat. The change then must be artificially rendered as gradual and imperceptible as possible; and the infant, during the first month, ought scarcely to be exposed to any sensible degree of cold, even for the shortest period. It has been with many midwives a common practice to direct that the new-born child be immediately washed with cold water, and other irritating

substances, in order to cleanse the surface of the body previously to its being covered with clothing. All that is necessary, or even proper, is the use of warm water and sponge, without any further friction, after washing, than what is necessary completely to dry the skin; indeed the propriety of washing, or in any way cleansing, the skin of an infant at birth, has lately been denied by an author whom we have already quoted; but we think that the use of tepid water, applied with gentleness, and without any subsequent violence of friction, can in no case be objectionable, but ought always to be had recourse to.

As soon as the process is completed, the infant is to be immediately clothed; and now let the habits of the common routine of nurses and of friends be as sedulously watched, and as earnestly opposed, as in relation to its diet. If the customary mode of feeding infants has induced a long train of present and permanent evils, the manner of dressing, (and which, till of very late years, has been persisted in with all the cruel pertinacity of contumacious ignorance), has also been productive of incalculable mischief. The evil is now diminished, but is not by any means destroyed. It has happened in this, as on every other occasion where the clamour of senseless conceits has been made to silence the simple and artless dictates of nature, that the most preposterous customs have obtained. "Physicians speculated about the infant's imperfect structure at birth, about the imperfect structure of his bones, the shapeless forms of his head, and the injuries he might sustain in birth; about injuries and distortions from hurtful motions and unnatural positions. They thought the infant's body unable to support itself, and that even its own motions might destroy it. Then in came the midwives for their share of the concern. The task was theirs to model the head, and to straighten the limbs; to improve upon nature; and to support their improvements by the application of fillets, rollers, and swaddling-bands. They vied with each other who should work the work most cunningly; for, strange to tell, dexterity in working this work of cruelty was reckoned one of their most necessary and important qualifications." Dr. Herdman.

In clothing, then, nothing further is requisite than to guard against the variations of external temperature, and to preserve a genial warmth for the maintenance of functions: the fillets, rollers, and bandages, of the nursery are not useless merely, but beyond measure dangerous. They are to be entirely laid aside, as implements of torture and destruction. No pressure on any part is to be employed. A broad strip of flannel or cotton loosely folded round the body is all that is requisite, even as a bandage for the navel. A thin single cap is the whole of the covering that the head requires or should receive. The body should be enveloped with a shirt of fine cotton, made loose and easy, over which should be a covering of flannel: and in a word, the dress is to be so constructed, that the rapid motion of the circulating fluids may be preserved without the smallest impediment. It may be necessary before quitting this subject, to state, that the writer's experience has convinced him of the propriety and importance of the above regulations in regard to dress and diet, even where relationship has ensured an attentive and unprejudiced scrutiny into particulars.

But it is not as it regards clothing merely that the medium to which a young infant is exposed demands assiduous attention; much care ought to be taken in providing likewise "a fit habitation for the expected little visitor." The apartment devoted to the rearing of infants, during the first months especially, ought to be so constructed and situated as to ensure a steady, equable, and mild temperature. Small confined nurseries, where it is possible, ought to be avoided. In such apartments it is difficult to guard against the extremes of either heat or cold. An exposure to a stream or current of air, occasioned by an unsuspected breach in the window, directed on the body of a sleeping infant, has often been productive of serious injury. Dr. Beddoes directs that the air of the nursery be never suffered to fall below fifty degrees; and it is always to be carefully retained in the memory, that the deficiencies occasioned by ill-constructed buildings can never be compensated by heaping fuel on the fire; by this custom indeed not only is the air rendered impure, but the temperature of the room is made still more irregular, and the danger of colds consequently increased.

There is one caution which is especially necessary with respect to the management and economy of nurseries. All occasions and sources of *damp* should most assiduously be guarded against. This caution is the more needful, because the danger from this source appears to be the least understood or suspected. It is not uncommon to observe that parents and nurses who would dread the opening of a sash-window, at the same time unwittingly expose themselves and their charge to a much greater degree of cold by permitting the suspension of wet clothes, in order to dry, about different parts of the apartment, and even by carelessness respecting the washing of the floor. The process of drying is the process of producing cold, and that too of the most noxious kind; for cold, when combined with moisture, has been proved, in an excessive degree, inimical to the animal economy. Damp is equally insidious and detrimental. We are fully persuaded that from this cause originate many scrophulous and other infantile ailments; and that where the diseases have been fancifully attributed to deleterious impregnations in the waters we drink, and various other sources. By every individual, but more especially by the parents and guardians of infancy and youth, freedom from damp should be the first and great requisite in the choice of apartments and houses.

But to return to the infant's dress. The covering which we have recommended ought to be continued for the first six or seven weeks of infancy; during this period, as we have already observed, nourishment, warmth, and repose, are almost its only requisites. After this time, however, or towards the close of the second month, the infant economy begins to change; vascular action comes now to be connected with voluntary muscular motion; the percipient faculty is gradually developed; and the whole organization appears to undergo a change. The body is now warmed in a greater degree and more regular manner, by actions of its own production, and heat of its own formation. Exterior warmth is daily less necessary; and that quantity and kind of clothing, which before were proper and genial, now become irksome and

debilitating. If with this progress of growth the summer months are at the same time about to appear, the covering of the child may, in a short time, be reduced even to a shirt and single external garment: the utility of this light clothing will be rendered evident by the feelings and expressions of the infant. It is almost unnecessary to observe, that general precepts are incapable of undeviating and indiscriminate application. The changes of the weather, the season of the year, and the delicacy or robustness of the constitution, will interfere with every rule, and give exercise to the independant judgment of every parent. Providence, however, has so ordained it, that in this, as in every other respect, the dictates of nature, which are communicated by the desire and aversion of the infant, furnish the most faithful directories with respect to its management; and these are conveyed with such distinctness and precision as to be generally intelligible. It is only by disobeying nature's laws that, in the treatment of infancy, we have wandered wide of the path of rectitude, and are under the necessity of retracing our steps.

We now close the present section by a few additional remarks on the much-contested question of bathing. It has already been observed, that an infant, upon its first entrance into the world, should be immediately washed with tepid or warm water. Others recommend immersion rather than ablution. " For a new-born infant (says Dr. Beddoes) I should prefer instant immersion in water at eighty degrees to washing." It is perhaps immaterial to which mode of cleansing we have recourse, unless the latter may be deemed objectionable on account of the unnecessary shock it may occasion to the tender frame. It is likewise to be observed, that conveniences for the former are procured with more facility than the latter; and that it is not every nursery that can, without difficulty, be furnished with a " proper vessel for a warm bath." The question, however, now to be resolved is, in what mode, and at what temperature, bathing or washing should be continued through the period of childhood. This question, like others, is incapable of decision by an appeal to separate principles. By one writer, daily immersion in, or ablution with, cold water, for the first two or three years of life, is earnestly recommended; by another, it is condemned as an unnecessary piece of cruelty, while tepid washing is directed to supply its place. Like the different decisions past on the cameleon's hue, these precepts, although opposite, may each be equally just. The weakly infant shall be washed " with cold water into irrecoverable debility," into convulsions and death; while to the robust and hardy child the same element at the same temperature shall be congenial, and by its use he will be prepared for the variations of cold and heat, to which he will in the course of life be exposed. In a popular treatise on consumption, recently published by Dr. Reid, we meet with the following judicious regulations on the subject of bathing: " It may be proper to premise (says our author), that by the cold bath is understood water at an inferior standard to eighty degrees of Fahrenheit's thermometer. Between this point and that of 90 degrees the bath may be termed temperate; and it is only beyond this last degree of heat that the epithet warm can with propriety be applied. From neglecting accurately to observe these distinctions, which are of very material importance, a want of precision has often connected itself with directions for the employment of both warm and cold bathing.

" Immersion in cold water, during the period of infancy, has been very generally recommended, and too often had recourse to, in an indiscriminate manner, to preserve health, and ensure hardiness. The author has remarked several instances where sensible, and sometimes considerable, injury has arisen from neglecting to observe the precautions necessary to regulate the employment of this important agent in very early years. In infancy danger to the lungs from cold bathing has been stated to exist in a very inferior degree; and by the practice of dipping children in cold water, susceptibility to the injurious impression of cold, in succeeding years, has been thought to be materially diminished. This principle, in the abstract, is undoubtely correct; and, with the exceptions and precautions now to be mentioned, may be pursued with propriety and advantage. Two infants may be supposed of one family of reverse constitutions. In the one a general torpor, debility, and great susceptibility to the impression of cold, shall prevail: in the other comparative vigour, activity, and warmth. That degree of cold which would refresh and invigorate the one, would confirm, debility and augment torpor in the other. A bath which is not cold to the sensations must, in the first instance at least, be resorted to for the weaker infant; and in neither case should immersion in cold water be practised when the external warmth of the body is inferior in degree to its general standard; when after immersion the body appears to be chilled, or when returning heat is attended with febrile languor, instead of the grateful and genial warmth characteristic of the appropriate action of exciting powers. If the practice of immersion is guided by a cautious observance of these particulars, it may be adopted with safety, and will be attended with success; but a total neglect of bathing would be greatly preferable to the severe and incautious manner in which infants are frequently exposed to these violent and rapid changes in the temperature." It ought to be added, that whether washing or immersion is employed, much care should be taken in drying the skin, particularly in those parts in which it is loosely situated, as about the groin, and in the arm-pits.

It may be necessary likewise to observe, that the breast ought on no account to be given to the child while being washed and dressed. A perseverance in this respect will ultimately prove of essential advantage. The habits of the child are greatly under the command of the parent or nurse. At the expense of a few temporary tears permanent comfort may be attained.

Sect. III.—*Air and exercise.*

It has recently been conjectured that the air we breathe contributes equally, and nearly in the same manner, to the nourishment of the body, with the aliment that is taken into the stomach: respecting the grounds of this opinion it would not be in place, in the present article, to institute any inquiry. (See Physiology; and Materia Medica, section Dietetics). We have here only to impress the necessity of a constant and unremitting regard to ventilation, in order to ensure a healthful condition in the infantile economy.

Both the truth and importance of this principle would seem too obvious even to require notice by a writer on regimen, had he not daily opportunities of witnessing the mischief arising from neglecting its application. The public mind, however, appears to be at length awakening from a long lethargy of prejudice and error. We at length begin to breath and to live. Even among the poorer and least informed classes of society, cleanliness and ventilation come to be acknowledged as the surest barriers against the invasion of disease. Although, however, on this subject modern science has much to boast, much likewise remains to be accomplished; and even in the present day examples cannot be too frequently pressed upon public observation of the injurious tendency, especially in the susceptible and delicate period of infancy, of neglected ventilation. "There is reason to suppose that, from the inattention of our ancestors to fresh air, multitudes must have perished in the very dawn of existence. In our times grown persons have been dangerously affected by such a deficiency of this necessary of life, as did not even produce immediate uneasiness. *Infants have perished in great numbers by a slow suffocation, terminating in convulsions.* As soon as the want of ventilation was observed the mortality has ceased." Beddoes. A fact, of which the following relation furnishes irrefragable evidence. In the lying in hospital at Dublin 2,944 infants, out of 7,650, died in the year 1782, within the first fortnight from their birth: they almost all expired in convulsions; many foamed at the mouth, their thumbs were drawn into the palms of their hands, their jaws were locked, their faces swelled, and they presented, in a greater or inferior degree, every appearance of suffocation. This last circumstance at length induced an inquiry whether the rooms were not too close, and insufficiently ventilated. The apartments of the hospital were rendered more airy; and the consequence has been, that the proportion of deaths, according to the register of the succeeding years, is diminished from three to one.

Such facts as these cannot be too often made to pass under review. By the parent anxious for the well-being of her offspring they ought constantly to be enforced upon the minds of servants and nurses, whose supineness in respect to proper ventilation is often only to be equalled by their mismanagement in other particulars. This indolence is often by servants carried to such an extent as very materially to injure their own health. "In a large family (says Dr. Darwin) many female servants slept in one room, which they had contrived to render inaccessible to every blast of air. I saw four who were thus seized with convulsions. They were removed into more airy apartments, but were some weeks before they all regained their health." Had infants unfortunately been confined in the same tainted atmosphere, convulsions in these would have been more readily induced, and might perhaps have proved fatal! A child then ought never, if it can be avoided, to be permitted to sleep with many individuals in the same apartment. It should not be lulled to rest in its nurse's arms. When put to sleep in the couch or cradle the face must not be covered; at night the clothes should be entirely changed; after the first or second month it should be daily taken out in the open air, when the weather is not cold or damp: this is best done in the forenoon, immediately upon being washed and dressed; care being taken that the infant is not carried too much in one position, and that it does not suffer from cold. Every impediment to the purity of the air within doors is to be as speedily as possible removed; and when the skin is preternaturally hot, or the little patient becomes restless and febrile, the fires of the nursery are to be extinguished, the windows thrown open, or the apartments changed.

To the full enjoyment of the atmosphere the free use of the limbs must likewise be added. On exercise scarcely any thing remains to be said. Freedom from all constraint is implied in the mode of dress above recommended. To those, however, who imagine that nature can be assisted by the contrivances of art, or that symmetry of form is to be insured by unnatural restriction, it may not be improper to observe, that deformities are only known in those countries where mechanical dexterity has been called upon to prevent them. "The infants of the Caffres (says the author of Travels into the interior of Southern Africa), soon after birth, are suffered to crawl about perfectly naked; and at six or seven months they are able to run. A cripple or deformed person is never seen. In Egypt, again, the haram is the cradle or school of infancy. The new-born feeble being is not there swaddled and fillited up in a swathe, the source of a thousand diseases. Laid naked on a mat, exposed in a vast chamber to the pure air, he breathes freely, and with his delicate limbs sprawls at pleasure. The new element in which he is to live is not entered with pain and tears. Daily bathed beneath his mother's eye he grows apace. Free to act he tries his coming powers; rolls, crawls, rises, and should he fall, cannot much hurt himself on the carpet or mat that covers the floor."

PART II.

DISEASES OF INFANCY.

SEC. I.—*Mesenteric atrophy* (Tabes mesenterica, Atrophia infantilis).

This is, in a great measure, the origin and root of the major part of infantile diseases. An affection of the mesenteric glands in children is often connected with, is not unusually the occasion of, and is still more frequently mistaken for, worms; it is the medium through which rickets are produced; it is, in general, the more immediate cause of diarrhœas, and other bowel complaints; and in several instances has been the "forerunner, if not the cause, of hydrocephalus, or dropsy in the brain."

Than this no complaint bears more evident characters. The physician who has been accustomed to the general aspect of infantile disorders, will most commonly commence his inquiries by an inspection of the abdomen. If he perceives a fulness and tenseness about the navel, and a general protuberance and hardness about the belly, attended sometimes with a knotty irregularity, indicating glandular tumefaction; and if, combined with this symptom, a tendency to atrophy, or, as it is called, falling away in flesh and strength, is observed; a greater or inferior degree of mesenteric consumption is present. Such then are the never-failing attendants of the disorder now under notice; they are its distinct and prominent features. A variety, however, of other adjunctive symptoms, for the most part, display themselves, and constitute part of the malady. Sometimes an universal languor and

listlessness will be connected with aversion to food; at others an inordinate appetite is present. The bowels are at times costive, but at others the contrary; the evacuations are discoloured, and unhealthy in their appearance; they are, for the most part, slimy, or viscid in their consistence, but are discharged, both with respect to quantity and quality, with the utmost irregularity: the countenance is pale, "except when the hectic flush prints its deceitful and ill-omened animation on the cheek:" the features are, for the most part, full and tumid: the eye is dull: the breathing is oppressed, and spasmodic: the pulse is invariably feeble, but is sometimes slow, and at others inordinately accelerated. In the advanced stages swellings of the feet and ancles are sometimes observed. The little sufferer generally moans piteously; and this, if the disorder has arrived to any considerable extent, is almost the only sign which is given of consciousness or feeling.

Causes.—Mesenteric atrophy is most prevalent among the children of the poor, especially in large cities, and in dirty confined situations. "The noxious powers producing it," in the language of Dr. Brown, (see BRUNONIAN SYSTEM.) "are the same with those of every other asthenia. They are want of food, or diet of watery matter and bread; cold and moisture, the latter increasing the effects of the former; too little nursing (gestationis justo minus); habitual vomiting and purging; irregularities in the times of sleep, meals, and every other part of infantile management; filth; impure air; an inattention to the instincts of nature in the treatment of children." Elementa Medicinæ. To these causes Dr. Brown ought to have added the practice of giving children fermented or spirituous liquors, and those other artificial stimuli, to which we have referred in the former part of the present essay. This custom is extremely prevalent in the inferior classes of society; and hence, in part, the frequency of mesenteric atrophy among the offspring of the poor.

Immediate cause of, and constitutions most obnoxious to, mesenteric consumptions.—The unusual bulk of the abdomen, which is so characteristic of this disease, obviously depends upon a deranged state of the mesenteric glands. The tumefaction, however, does not arise from the source to which it is vulgarly referred, "the presence of tough, ropy humours, causing an obstruction in the tumefied parts." The theory of mechanical obstruction is indeed totally founded in error. It is inconsistent with the laws of the animal economy. It is incompatible with living action; and, as we shall immediately have occasion to observe, has been the cause of much and serious mischief, both in the domestic, and even the professional treatment, of this and other ailments. "The idea of attenuating humours, purifying blood, and clearing passages, rests upon a wrong principle." So far indeed from the glands of the mesentery being less permeable under disease than when in a state of health, the exact contrary is the fact; and not only is their area enlarged, but new vessels are often at the same time formed; and hence the morbid increase of bulk.

The attendant atrophy is easy of explanation. The deranged action of the glands in question interferes with the due preparation of the chyle, the whole of which has to undergo a preparation in these organs. The chyle is the fluid from which the blood is formed: on the quantity and quality of the blood depend health, growth, and life; by its deficiency, or want of due proportion in its component principles, debility, disease, and atrophy, are produced.

The attendant symptoms are not difficult to account for; the torpid and irregular state of the bowels is partly owing to the general inactivity in the lymphatics of the liver; hence the thinner portions of the bile remain unabsorbed, and this fluid is in consequence too diluted to afford a due excitation to the intestinal fibre. The sliminess and viscidity of the fæces arise from the disordered state of the glands of the intestines; and the œdematous swellings of the feet are evidences of a general inactivity, or deficient excitement, pervading the whole lymphatic system.

The constitutions in which tabes mesenterica most readily makes its appearance, are those which are denominated scrophulous. The marks of scrophula we shall not here enumerate; it may be sufficient to observe, that in habits of this description the lymphatic and glandular systems are especially prone to suffer from the exciting causes of disease. This indeed is more or less the case in every individual during growth, as, at this period of existence, the office which these vessels perform in the animal economy, is more important and complicated than in the succeeding stages of life.

Treatment.—The most effectual remedies are necessarily the converse of those which occasioned the disease. These we shall likewise enumerate from the Elements of Dr. Brown: "nourishing exciting milk; three or four meals in the course of the day, composed chiefly of warm milk; pure animal, and by no means weak, soups, mixed with wheaten flour or bread; a due temperature, so that a genial warmth may be preserved, without producing irritation, or occasioning too copious sweat; avoiding every species of evacuation; good nursing; a proper regulation of the times of sleep, food, and every other circumstance connected with the management of the susceptible and tender condition of infancy; cleanliness; tepid bathing in moderately cold weather, and cold bathing in warm; pure air; being sent out of doors as much as possible, excepting when the weather is damp; and, finally, a judicious attention to desires and propensities; this ought to be carried to such an extent as to obviate, if possible, the most trifling local irritation, as by the scratching of a part that itches.

The above are necessarily adapted to the milder forms of the complaint. When the disorder has arrived to a certain extent, medicinal is now required in aid of domestic treatment: for although the mesenteric atrophy, unless it is a consequence of defective structure, may at all times be prevented, and in its earlier stages with facility combated, without the aid of drugs; these, at length, come to be absolutely indispensable. It ought, however, to be impressed on the public mind, that pharmacy, although it may correct the errors, can in no wise become a substitute for, or supply the deficiencies of, regimen.

The objects of the medical practitioner, in the treatment of the disease in question, will be twofold. 1st. That of immediately and forcibly stimulating the lacteals and mesenteric glands; and, 2dly, the preservation

of a due and equable excitement in order to obviate the recurrence of the disorder.

[N. B. For the explanation of any terms that may not be familiar, the reader is referred to the articles ANATOMY, PHYSIOLOGY, and MEDICINE.]

The first of the above intentions is most speedily and effectually accomplished by mercurial purgatives: and of these calomel (submurias hydrargyri) is generally to be preferred. The benefit which has often resulted from preparations of mercury, particularly in the form of calomel, has frequently been accounted for upon very erroneous principles. It is customary to attribute every complaint of childhood, where the stomach and intestines show marks of derangement, to worms. With the signs of the actual existence of the animalculæ, we have already remarked those of tabes mesenterica are, from their affinity, often confounded. Advertisements of infallible cures for worms, as indeed for every other malady, are constantly before the public: these, for the most part, contain mercury, as the only agent of consequence in their composition; and from the operation of this medicine upon the diseased glands, provided, by accident, the quantity taken is proportioned to the age and constitution of the recipient, immediate, and temporary relief is perceptible. Worms are supposed to be expelled the system, and the infallible medicine is indiscriminately, and often fatally, circulated among the public.

A further error with respect to the agency of calomel in the mesenteric affections, is that of attributing its effects solely to its purgative quality. This last error is not confined to the unprofessional. Ill-founded notions, as we have above hinted, are still too general in regard to obstructing humours; and the cure of this disorder, with all others which are conjectured to arise from obstruction, is consequently imagined to be performed by evacuating medicines. We are disposed to believe that a recent publication, although in the main extremely useful, has, by the unqualified recommendation of purgatives, given too much encouragement to this mistaken principle.

Dr. Hamilton, the author of the work to which we allude, has classed, under the title of marasmus, the asthenic affections which are common to young persons, and of which the disorder now under consideration is one of the most general; and these affections he "is convinced have often been removed by the diligent exhibition of purgative medicines." Now we are fully persuaded, although actual, and even repeated, purgations are in many cases indispensable; that for the most part, especially in "incipient marasmus," such a qualification in the dose of cathartics is to be preferred as may ensure an excitation of the glandular, lacteal, and lymphatic organs (the organs principally concerned in the production of the complaints in question), without copiously evacuating the contents of the bowels. For this persuasion we have the authority of experience. Further, it is to be remarked, even where large and repeated evacuations, in these diseases of debility especially, have been followed by beneficial effects, that, even then, the evacuation itself has constituted but a share in the process of recovery. This principle may be evidenced in the example of either vomiting or purging. Let a case be supposed of mesenteric affection carried to such an extent, that the torpid condition of the lacteal glands has extended itself to the hepatic and biliary organs; where even dropsical effusions have taken place, and contributed to the enlargement of the belly; and where this abdominal protuberance is contrasted, in a most distressing degree, with the emaciation of the limbs. Under these circumstances (and the writer of the present article has witnessed them in the full extent described), if either a quantity of ipecacuana, emetic tartar, or any other emetic drug, is given sufficient to occasion vomiting, or such a dose of calomel as alone, or in combination, may produce a copious alvine discharge: the immediate result will prove, that the principal part of the medicinal agency has been constituted by a sudden and powerful impulse communicated to the glandular and absorbent vessels. The liver shall commence a regular secretion of bile, the fæces in consequence assume a proper colour and consistence, the skin shall lose suddenly its sallow sickly hue, the size of the abdomen be lessened, and even the swellings of the ancles be diminished; all evincing, in the most unequivocal manner, an increased action in the absorbent system.

By those who are aware of the importance of acquiring correct notions in respect to medicinal agency, the above remarks, although perhaps in some measure irregularly introduced, will not be deemed misplaced. They will, it is hoped, facilitate the conception, and serve to curtail the discussion, of the remaining disorders that are to be treated of in this article.

We now recur to the more immediate subject of the present section.

We have observed, that the first object of the physician, in cases of deeply rooted mesenteric disorder, is to produce an immediate and forcible excitement in the lacteal glands; the manner in which this object is to be attained may be gathered from the preceding remarks. Either calomel purgatives, or emetic substances, are to be employed, according to the circumstances of the case, or the inclination of the practitioner; and now the judicious regulations of diet and regimen prescribed by Brown, are to be assisted by medicines, in order to accomplish the second purpose, that of preserving a due excitement to secure against the recurrence of the disease.

The physician will be careful to keep in view, that the absorbent system is principally concerned in this, as well as in the other asthenia of infants. It is to this part of the frame that remedies are especially to be directed. Among the various stimuli, those therefore are to be preferred, the influence of which appears in an especial manner to be directed to this part of the organization. Chalybeates have this property in a remarkable degree; and accordingly one or other of the various preparations of steel has been judiciously and successfully had recourse to in tabes mesenterica: these are to be conjoined with pure air, and due exercise, without which the most appropriate medicines will be in vain administered. The continued use of small doses of calomel, or other mercurial preparations, either in conjunction with, and sometimes to the exclusion of, steel, will prove highly useful in restoring a due energy and action to the absorbents. These, like all other active medicinals, require much address and discrimination in

their employment. It is from the presence of mercury, as above hinted, that both the utility and dangerous tendency of quack medicines are for the most part derived.

In the practice of the writer of this article, extremely small, and very gradually augmented, doses of digitalis have appeared to restore, in a remarkable degree, the wonted vigour of the lacteal vessels. The free use of this very important and active medicine has long been admitted in dropsy, an affection generally attended with great debility. In tabes mesenterica we believe its employment is novel; but we are, at the same time, persuaded, from the result of several cases of this and other modifications of infantile asthenia, that foxglove might be made, under due regulation, a very successful agent in the treatment of these complaints. Under these circumstances, on account of the comparative minuteness of the dose, the digitalis is best given in the form of tincture; a preparation which has not hitherto been received into the London Pharmacopeia. See Materia Medica, and Pharmacy.

Sect. II.—*Water in the head.* (Hydrocephalus.)

The discriminating characters of this disease demand assiduous attention from the medical practitioner. It cannot be doubted that a great number of children are constantly destroyed by water in the brain, where the nature of the malady has been entirely misunderstood, and the symptoms referred to other sources, most commonly worms; while, on the other hand, hydrocephalus has been very frequently suspected, and the event has proved that the suspicion was destitute of any proper foundation.

Hydrocephalus is generally divided by authors into the internal, or that in which the fluid is contained in the ventricles of the brain; and external, where the disease is exterior to the substance of this organ, and the water is found in its investing membranes. The first species has likewise been denominated acute, the second chronic. This division, however, is calculated to mislead; not merely on account of the frequent connection between the two species (internal and external) of hydrocephalus, but because the former, as well as the latter, is oftentimes chronic, and by no means necessarily preceded by an inflammatory affection of the parts concerned in its production.

The chronic internal, chronic external, and the acute, species of hydrocephalus, would constitute a classification of the disease, approaching nearer to accuracy than that which has been hitherto adopted; and we shall proceed to give a brief description of each, requesting the reader to recollect that the different kinds are often mixed, and consequently exhibit characters in an almost endless variety.

Chronic internal.—This, although overlooked in the ordinary division, is perhaps the most usual form in which the affection presents itself; it arises from the same disposition in the habit, and is oftentimes combined with the disease treated of in the preceding section. More commonly, however, it is in a manner vicarious of this last; and the same causes may, perhaps from accidental circumstances, at one time occasion tabes mesenterica, which would at another have produced hydrocephalus. Its symptoms are less decided than those of the other species. When, however, in children of a sluggish habit, or scrophulous constitution, an unusual drowsiness or stupor is present, the child gradually loses his vivacity and spirits, is indisposed to make any exertion of his limbs, is unusually fretful and peevish, complains or exhibits signs of an uneasiness in the head, is affected with convulsive fits without any apparent cause, has an unusually tardy pulse, and more especially if the pupil of the eye is not found to contract upon the application of light, there is reason to suspect the presence of water in the brain, although there may be no symptoms of external disease, and no preternatural enlargement of the head, except what is usually met with in young persons of a torpid scrophulous habit; and the suspicion has been too often confirmed by dissection, even where a fatal termination has happened, without being preceded, during any period of the malady, by the symptoms immediately to be mentioned, characteristic of the acute species. This first kind of hydrocephalus is succinctly described by Dr. Heberden, in the following words: "Capitis dolores, manus ad caput crebro admotæ, clamores subiti, distensio nervorum, stupor, mentis perturbatio, motus venarum lentus, postremo cæcitas." He adds, "Justam hujus morbi suspicionem injiciunt hæc symptomata etiamsi capitis moles non fuerit aucta."

Chronic external.—The head of an infant at, or soon after, the period of birth exhibits a preternatural size and form; the regular process of ossification does not take place; but the principal part of the external surface of the cranium continues soft and yielding, while not unfrequently, in the progress of the complaint, an undulation of a fluid may be perceived by applying the hand to the sutures of the skull. As the disease continues to advance, the signs of its existence become shortly obvious to the most superficial observation; not only does the head increase to an enormous size, but the growth of other parts is in a proportionate ratio defective; the limbs do not often acquire a much greater bulk than at birth; at the ordinary period of teething no teeth present themselves; the percipient faculty is not gradually unfolded, as in other infants; and, indeed, although vitality is preserved, it appears to be a vitality almost entirely unconnected with feeling. In this state of torpid existence life however is, in some instances, prolonged for four, six, or even a greater number of years. In the Commentaries of Van Sweiten, we have the relation of life being maintained under this malady for thirty years: this, however, is an anomaly; and indeed the hydrocephalic patient seldom survives the second year.

Acute hydrocephalus.—The acute, phrenitic, inflammatory, or, as it has been termed by some writers, apoplectic hydrocephalus, is not, like the other species, entirely confined to any constitution. Although most frequent in children under twelve years, it is sometimes observed in adults. It has been divided by Dr. Whytt, and others who have followed him, into three distinct stages: the first of which is invariably characterised by a pulse of much celerity and comparative strength; in the second the pulsations become slower, and more feeble; in the third and last period their rapidity is increased even beyond that of the primary stage; but this increased action is now connected with extreme debility. These different changes in the circulation are not, however, always

to be traced even in the acute species of hydrocephalus, in that order which the observations of Dr. Whytt would lead us to suppose.

Obscure affections of the stomach, a general feeling of lassitude, with sometimes a kind of palsy of the limbs, or an affection of them, in some measure similar to that observed in St. Vitus's dance, if the child has previously been able to walk, sometimes present themselves as precursors of the first, or the inflammatory stage; at other times the feverish state, intolerance of light, violent pains in the head, and vomiting, are the first signs of disorder that are noticed. These symptoms are in some cases connected, according to the observations of Dr. Rush, with an impatience of sound; the pain of the head is often confined to one side; and in proportion to its intensity the nausea and vomiting becomes less urgent, while with the remission of the pain these affections of the stomach are disposed to recur. Respiration at this time is spasmodic and irregular; the bowels are generally so costive as to require very drastic purgatives, in order to produce evacuations. This state of the complaint continues sometimes for several days, but is more usually in a shorter period succeeded by the second, which commences by a sudden reduction of the pulse, and other symptoms of irritation. The pain of the head now becomes less urgent, torpor succeeds to watchfulness, the infant lifts his hands to his head, and frequently utters piercing screams (clamores subiti); a degree of strabismus takes place of the previously morbid susceptibility of light; the little patient lies in an horizontal posture, with the head low, and shows an indisposition to be taken up; the bowels still continue torpid; the urine not unfrequently deposits a thick sediment; and after these symptoms have lasted from seven to fourteen days, the complaint sometimes appears suddenly to decline. This semblance of returning health is, however, deceitful, and is but a prelude to the final period of the complaint: it is now that the pulse increases in frequency, and oftentimes so quick as not to be counted. Dr. Whytt informs us that in some children he has been able to number 210 pulsations in the space of a minute; this extraordinary rapidity, however, does not last through the whole of the day; it comes on and declines with the accessions and remissions of the hectic flush in the cheek. The eyes at length become insensible to the strongest light, convulsions come on, and life is terminated. The duration of this last period, like that of the others, is irregular. Sometimes the patient is carried off in less than a week from its commencement; at other times the child lingers in a hectic state for three, four, or six weeks; and Dr. Monro has informed us, that the last state has been known to be protracted even to the fourth month.

Causes.—The two first species of the complaint are decidedly of a scrophulous nature. They generally come on without any evident exciting cause, and, like other asthenic affections, in the early periods of life, originate from lymphatic debility, without previous excitement in the vessels of the brain to produce the effusion: the last species is perhaps always preceded by an inflammation in the internal vessels of the brain. The immediate cause of this irritation is not, however, in every instance to be detected; it may arise in subjects predisposed, in common with all other inflammations, from the sudden alternations of cold and heat. It has been observed to supervene upon the contagious eruptive affections, especially when these have been unusually violent; and Dr. Beddoes, in a letter to Dr. Darwin, inquires "whether it may not happen more frequently than has been suspected from external injury?" Zoonomia.

Treatment.—Evacuations of every kind, viz. cathartics, sudorifics, emetics, general and local blood-letting, as well as the external application of cold, and of blisters to the scalp, with due attention to the erect position of the head, had all, in conjunction or separately, been tried in the acute species of hydrocephalus, but, according to the general report of physicians, without effect. It is in what Dr. Whytt has called the first state of hydrocephalus that the above treatment should be vigorously put in practice, and it is only in this stage that we can look with confidence for a successful issue from any treatment. When a collection of water has actually taken place within the ventricles of the brain, the disease has almost invariably ended in death.

In consequence, therefore, of the ill success that had attended the common routine of treatment in hydrocephalus, Dr. Dobson, of Liverpool, was induced to make trial of mercurials, with an intention of exciting the absorbents of the brain, and in this manner removing the extravasated fluid. The event appeared to justify his theory; and we have several cases recorded by this physician and by others, in which mercury, carried to the extent of salivation, accomplished a speedy and effectual cure. The following case is from Dr. Percival: "One of my own children, a girl, aged three years and three months, has lately been a severe sufferer under this alarming malady. As soon as the characteristic symptoms of the disease clearly manifested themselves, I laid aside all other remedies, convinced by repeated observation of their insufficiency, and trusted solely, though with much solicitude, to the internal and external use of mercury. In forty-eight hours, signs of amendment appeared, and her recovery was perfected in six days. During this space of time, thirteen grains of calomel were administered, and seven scruples of unguentum mercuriale fortius carefully rubbed into the legs."

With the same design of exciting the absorbents, digitalis has recently been employed. "In one child," says Dr. Darwin, "I tried the foxglove in tincture, but it was given with too timid a hand and too late in the disease to determine its effects." In the work of Dr. Reid, to which we referred in a former part of this article, we meet with the following observations: "The universality of lymphatic absorbents is rather conceived than actually demonstrated. Dissection has hitherto not been able to detect these vessels in the brain; analogy, however, favours the supposition of their existence. If that frequent and too fatal disease of young persons, water in the brain, admits of cure, the remedies which effect it, must necessarily operate by producing an absorption of the effused fluid. The author imagines he has witnessed the cure of hydrocephalus by means of foxglove. The symptoms, however, of worms and other infantile affections, so oftem resemble those indicative of water in the ventricles of the brain, that it is scarcely possible to decide with absolute certainty on the interesting question of the

inevitable fatality or remediable nature of hydrocephalus."

If foxglove should be proved by future experience to succeed as a remedy for this alarming malady, its modus operandi must be referred to the extraordinary faculty which it possesses of repressing the arterial, while it stimulates the absorbent system. Both in the acute and chronic hydrocephalus, it appears to be deserving of a more extensive trial. To the earlier stages of the former we should, *a priori*, be disposed to conceive it more applicable than even mercury.

Sect. III.—*Worms.* (Vermes.)

The marks by which the presence of worms is indicated are confessedly at times, both in the infant and adult, obscure and equivocal. In the majority of cases, however, the phenomena which they present require only for their detection a careful and discerning scrutiny.

In persons affected with worms, the countenance in general has a peculiar livid and dirty kind of appearance, very different from that which characterizes mere lymphatic debility, as in tabes mesenterica, and hydrocephalus. The eyes become dull, the pupil dilated, but not averse to light, as in hydrocephalus, the upper lip swelled, the sides of the nostrils enlarged, and there is almost constantly a violent itching of their internal membrane. The breath is remarkably offensive, saliva is secreted in unusual abundance; during sleep there is most generally some grinding of the teeth, and epileptic affections are by no means uncommon; the pulse is intermittent, the febrile irritation is not always of the hectic kind, the appetite is often voracious, lancinating pains are complained of in the stomach and bowels, and tenesmus, attended with a distressing irritation about the anus, is, especially from some species of worms, exceedingly frequent. Cough is not uncommon. These last, however, are more frequent symptoms in the adult than in the child. See Medicine.

Causes.—"The tumid belly, bloated countenance, and swelled upper lip," says Dr. Darwin, "are concommitant circumstances attending the general inactivity of the absorbent system, which is therefore to be esteemed the remote cause of the generation of worms." Worms, however, are often produced through the medium of intestinal vicidities, independantly of the absorbent vessels. The immediately exciting causes are some of those already mentioned as productive of mesenteric atrophy, more especially the reception into the stomach of indigestible substances. Dr. Darwin, indeed, supposes, that not merely the nidus of worms is thus formed from aliment incapable of assimilation, but that these animalculæ are actually received from without: for this opinion, however, there does not appear any foundation. Worms are actually engendered in the alimentary passage.

Treatment.—Emetics; mercurial purgatives, chalybeates; vegetable bitters; avoiding indigestible aliment. For an account of the different kinds of worms, and specific anthelmintics, consult the articles Medicine and Materia Medica.

Sect. IV.—*Rickets.* (Rachites. Atrophia infantilis.)

This is likewise an affection of the lymphatic system. Every one knows the characters by which it is marked. An infant with a large head, protuberant forehead, swellings in the smaller joints, depressed flattened ribs, emaciated limbs, and tumid abdomen, is decidedly rickety. These symptoms, in common with the other astheniæ of infants, usually make their appearance before the second year. The first indication of a rickety tendency is a remarkable flaccidity of the muscular fibre; disinclination to exertion follows; and the irregularities above enumerated shortly supervene, followed by hectic, cough, confirmed atrophy, death, or permanently distorted limbs.

Causes.—Debility, most commonly of an hereditary nature, constitutes the predisposition to rickets. Bad air, bad nursing, improper diet, uncleanliness, and damp, are its exciting causes. Hoffman describes the proximate cause to be a deficient supply of nervous influence to the spinal marrow, preventing the due nutrition of parts. Dr. Cullen supposes, a deficiency of bony matter in the fluids constitutes the disease. A more correct account, however, of the essentials of rickets, would make it to consist in deficient excitement or power in those vessels, by the action of which osseous matter is thrown out, and bone constituted.

Treatment.—Indication 1st. To cleanse the first passages from obstructions. Methodus medendi: emetics, cathartics, calomel.

Indication 2d. To restore due energy to the secretory vessels of the bones. M. M. chalybeates, exercise, bathing.

Sect. V.—*Disorder in the bowels.* (Diarrhœa infantilis.)

Among the morbi infantiles in the yearly catalogue of every medical practitioner, diarrhœa occupies a conspicuous situation. The griping, green and otherwise discoloured fæces, pains in the abdomen, with drawing up of the knees towards the stomach, severe crying, febrile irritation, and a greater or less degree of actual convulsions, are perhaps the most common among the diseases of infancy.

Causes.—These affections, as we have already observed, are almost invariably occasioned by improper diet. Dr. Darwin gives us the following relation: "A child of a week old, which had been taken from the breast of its dying mother, and had by some uncommon error been suffered to take no food but water-gruel, became sick and griped in 24 hours, was convulsed on the second day, and died on the third!" He adds, "That among the poor children of Derby who are thus fed hundreds are starved into scrophula, and either perish or live in a state of wretched debility." Zoonomia.

Treatment.—Calomel, with rhubard, is to be immediately given, which is to be followed by antacids, such as prepared chalk and magnesia. With these are to be connected, according to the violence of the disorder, aromatics and stimulants, such as cinnamon, nutmeg, and opium. Sometimes it is necessary to give an emetic. In all cases indigestible food is to be avoided.

Sect. VI.—*Affections occasioned by teething.* (Dentitio.)

Pains in the head, convulsions, frequent and sudden startings, more especially in sleep, eruptions on the skin, disorders of the stomach and bowels, cough, and hectic fever, are not unfrequently occasioned by the process of toothing. Dr. Darwin conjectures, that "the pain of toothing often begins much earlier than is suspected;"

and that the apparent cause of the disease is in reality its cure, as the convulsions, which are oftentimes the most violent and then by far the most alarming of the above symptoms, are commonly relieved when "the gum swells and becomes inflammed; at other times a diarrhœa supervenes, which is generally esteemed a favourable circumstance."

In difficult dentition, the pains in the head, convulsions, vomiting, and hectic, sometimes give rise to the suspicion of hydrocephalus: from this, however, the disease in question may generally be distinguished with facility by the ease with which, in the last case, the bowels are evacuated; by the inflammatory redness of the gum, and by the pupil of the eye being dilated in an obscure, and contracted in a vivid light, the contrary of which takes place in hydrocephalus.

Treatment.—Frequent doses of rhubarb, with magnesia, will often allay the intestinal irritation, and mitigate the teething cough. The gums are to be lanced in all cases where the redness and swelling are considerable. This practice can indeed never be objectionable. Antispasmodics for the convulsions are inefficacious while the cause remains.

Sect. VII.—*Croup.* (Cynanche trachealis.)

The characteristics, or pathognomic symptoms of this disease are, difficult respiration, loud and stridulous cough, with the emission of a sound of a peculiar nature, which has been compared to the crow of a young cock.

These symptoms sometimes supervene, upon the common precursors of violent inflammation; at other times the disease is formed without previous warning, and has been known to prove fatal in a very few hours from its apparent commencement. If life is not speedily terminated in this manner, the disorder frequently runs on for the space of six days, and terminates for the most part by crisis, with the evacuation of much pale urine.

Causes.—The croup is an inflammation of the upper part, as the peripeneumony is of the lower part of the same organ, viz. the trachea or windpipe. It originates from the same sources as other inflammation. The circumstance of its frequent occurrence and fatal tendency in infants, appears to be owing to the extremely disproportionate smallness of the glottis at this period of life. The cause of death, when it happens suddenly, is a deposition of concreted mucus (consequent upon the inflammation), which lines the trachea, and fills up the bronchial cavities. Independantly, however, of this circumstance, sudden death may be occasioned by the great loss of power in the muscular fibres of the glottis, induced by the previously high excitement. "infantes enim miram incitationis vicissitucinem, brevissimis temporum spatiis, experiuntur."

Treatment.—This, to be effectual, must be speedy and decisive. Emetics; copious bleeding from the arm, and leeches applied near to the part affected; blisters; warm bath; antimonials. Recently, calomel in large doses has been tried, and with success. Might not digitalis prove useful in consequence of its extraordinary power in rapidly reducing arterial excitement?

N. B. Croup, in some instances, assumes more of the asthenic than of the inflammatory nature; and in this case the disorder of the glottis is often protracted to a longer period. The treatment in this latter species requires to be stimulating. Calomel; opiates; blisters; volatile embrocations to the throat; nourishing diet.

For those diseases of young persons which often require local, in connection with general treatment, such as distortions of the spine, affections of the eyes, scrophulous swellings of lymphatic glands, &c. consult the article Surgery.

For eruptive and contagious diseases, see Medicine.

INFANT. From the observations daily made on the actions of infants, as to their arriving at discretion, the laws and customs of every country have fixed upon particular periods, on which they are presumed capable of acting with reason and discretion; in our law the full age of man or woman is 21 years. 3 Bac. Abr. 118.

The ages of male and female are different for different purposes: a male at 12 years of age may take the oath of allegiance; at 14 is at discretion, and therefore may consent or disagree to marriage; may choose his guardian, and if his discretion is actually proved, may make his testament of his personal estate; at 17 he may be a procurator or an executor; and at 21 is at his own disposal, and may alien his lands, goods, and chattels. A female at seven years of age may be betrothed or given in marriage; at nine is entitled to dower; and at 12 is of years of maturity, and therefore may consent or disagree to marriage, and if proved to have sufficient discretion may bequeath her personal estate; at 14 is at years of legal discretion, and may choose a guardian; at 17 may be executrix; and at 21 may dispose of herself and her lands. 1 Black. 463.

An infant is capable of inheriting, for the law presumes him capable of property; also an infant may purchase, because it is intended for his benefit, and the freehold is in him till he disagrees thereto, because an agreement is presumed, it being for his benefit, and because the freehold cannot be in the grantor contrary to his own act, nor can be in abeyance, for then a stranger would not know against whom to demand his right; and if at his full age the infant agrees to the purchase, he cannot afterwards avoid it; but if he dies during his minority his heirs may avoid it, for they shall not be bound by the contracts of a person who wanted capacity to contract. Co. Litt. 2.

As to infants being witnesses, there seems to be no fixed time at which children are excluded from giving evidence; but it will depend in a great measure on the sense and understanding of the children, as it shall appear on examination in court. Bull. N. P. 293.

And where they are admitted, concurrent testimony seems peculiarly desirable. 4 Bla. 214.

An infant is not bound by his contract to deliver a thing; so if one deliver goods to an infant upon a contract, &c. knowing him to be an infant, he shall not be chargeable in trover and conversion, or any other action for them; for the infant is not capable of any contract but for necessaries, therefore such delivery is a gift to the infant; but if an infant, without any contract, wilfully takes away the goods of another, trover lies against him; also it is said, that if he takes the goods under pretence that he is of full age, trover lies, because it is a wilful and fraudulent trespass. 1 Sid. 129.

Infants are disabled to contract for any thing but neces-

saries for their person, suitable to their degree and quality; and what is necessary must be left to the jury. Co. Litt. 172.

An infant, knowing of a fraud, shall be as much bound as if of age. 13 Vin. Abr. 536.

But it is held that this rule is confined to such acts only as are voidable; and that a warrant of attorney given by an infant being absolutely void, the court will not confirm it, though the infant appeared to have given it, knowing it was not good, and for the purpose of collusion.

As to acts of infants being void, or only voidable, there is a diversity between an actual delivery of the thing contracted for, and a bare agreement to deliver it; the first is voidable, but the last absolutely void.

As necessaries for an infant's wife are necessaries for him, he is chargeable for them, unless provided before marriage; in which case he is not answerable, though she wore them afterward. 1 Str. 168.

An infant is also liable for the nursing of his lawful child.

Where goods are furnished to the son, he is himself liable if they are necessaries. If tradesmen deal with him, and he undertakes to pay them, they must resort to him for payment; but if they furnished the infant on the credit of his father, the father only is liable. 2 Esp. 471.

With respect to education, &c. infants may be charged, where the credit was given bona fide to them. But where the infant is under the parent's power, and living in the house with them, he shall not be liable even for necessaries. 2 Black. Rep. 1325.

If a taylor trusts a young man, under age, for clothes to an extravagant degree, he cannot recover; and he is bound to know whether he deals at the same time with any other taylor. 1 Esp. Rep. 212.

If one lends money to an infant to pay a debt for necessaries, and he pays it, although he is not bound in law, it is said he is in equity; but if the infant misapplies the money it is at the peril of the lender.

A promissory note given by an infant for board and lodging. and for teaching him a trade, is valid, and will support an action for the money. 1 T. R. 41.

And debts contracted during infancy are good considerations to support a promise made to them when a person is of full age; but the promise must be express.

A bond without a penalty for necessaries will bind an infant, but not a bond with a penalty. Esp. Rep. 164.

Legacies to infants cannot be paid either to them or their parents.

An infant cannot be a juror, neither can he be an attorney, bailiff, factor, or receiver. Co. Lit. 172.

By the custom of London an infant unmarried, and above the age of 14, if under 21, may bind himself apprentice to a freeman of London, by indenture with proper covenants, which covenants, by the custom of London, will be as binding as if of age.

If an infant draws a bill of exchange, yet he shall not be liable on the custom of merchants; but he may plead infancy in the same manner as he may to any other contract.

An infant cannot be sued but under the protection and joining the name of his guardian; but he may sue either by his guardian, or his next friend, who is not his guardian. Co. Lit. 135.

An action on an account stated will not lie against an infant, though it should be for necessaries. Co. Lit. 172.

INFINITE, or INFINITELY GREAT LINE, in geometry, denotes only an indefinite or indeterminate line, to which no certain bounds, or limits, are prescribed.

INFINITESIMALS, among mathematicians, are defined to be infinitely small quantities.

In the method of infinitesimals, the element, by which any quantity increases or decreases, is supposed to be infinitely small, and is generally expressed by two or more terms, some of which are infinitely less than the rest, which being neglected as of no importance, the remaining terms form what is called the difference of the proposed quantity. The terms that are neglected in this manner, as infinitely less than the other terms of the element, are the very same which arise in consequence of the acceleration, or retardation, of the generating motion, during the infinitely small time in which the element is generated; so that the remaining terms express the elements that would have been produced in that time, if the generating motion had continued uniform: therefore those differences are accurately in the same ratio to each other as the generating motions or fluxions. And hence, though in this method infinitesimal parts of the elements are neglected, the conclusions are accurately true without even an infinitely small error, and agree precisely with those that are deduced by the method by fluxions.

For example, (see Plate LXXII. Miscel. fig. 136), when DG, the increment of the base AD, of the triangle ADE, is supposed to become infinitely little, the trapezium DGHE (the simultaneous increment of the triangle) consists of two parts, the parallelogram EG, and the triangle EIH; the latter of which is infinitely less than the former, their ratio being that of one-half DG to AD: therefore, according to this method in fluxions, the part EIH is neglected, and the remaining part, viz. the parallelogram EG, is the difference of the triangle ADE. Now it might be shown, that EG is precisely that part of the increment of the triangle ADE which is generated by the motion with which the triangle flows, and that EIH is the part of the same increment which is generated in consequence of the acceleration of this motion, while the base, by flowing uniformly, acquires the augment DG, whether DG be supposed finite or infinitely less.

Example 2. The increment DELMHG (fig. 137) of the rectangle AE, consists of the parallelograms EG, EM, and I*h*; the last of which, I*h*, becomes infinitely less than EG, or EM, when DG and LM, the increments of the sides, are supposed infinitely small; because I*h* is supposed to be to EG as LM to AL, and to EM as DG to AD; therefore, I*h* being neglected, the sum of the parallelograms EG and EM is the difference of the rectangle AE: and the sum of EG and EM is the space that would have been generated by the motion with which the rectangle AE flows continued uniformly, but that I*h* is the part of the increment of the rectangle which is generated in consequence of the acceleration of this motion, in the time that AD and AL, by flowing uniformly, acquire the augments DG and LM. The same may be observed in propositions wherein the fluxions of quan-

tities are determined; and thus the manner of investigating the differences, or fluxions of quantities, in the method of infinitesimals, may be deduced from the principles of the method of fluxions. For instead of neglecting EIH because it is infinitely less than EG, (according to the usual manner of reasoning in that method), we may reject it; because we may thence conclude, that it is not produced in consequence of the generating motion DG, but of the subsequent variations of this motion. And it appears why the conclusions in the method of infinitesimals are not to be represented as if they were only near the truth, but are to be held as accurately true.

In order to render the application of this method easy, some analogons principles are admitted, as that the infinitely small elements of a curve are right lines, or that a curve is a polygon of an infinite number of sides, which being produced, give the tangents of the curve; and by their inclination to each other measure the curvature. This is as if we should suppose, when the base flows uniformly, the ordinate flows with a motion which is uniform for every infinitely small part of time, and increases or decreases by infinitely small differences at the end of every such time.

But however convenient this principle may be, it must be applied with caution and art on various occasions. It is usual therefore, in many cases, to resolve the element of the curve into two or more infinitely small right lines; and sometimes it is necessary, if we would avoid error, to resolve it into an infinite number of such right lines, which are infinitesimals of the second order. In general, it is a postulatum in this method, that we may descend to the infinitesimals of any order whatever, as we find it necessary; by which means any error that might arise in the application of it may be discoverd and corrected by a proper use of this method itself. For an example of this, see Maclaurin's Fluxions.

INFLAMMABILITY, that property of bodies which disposes them to kindle or catch fire. See CALORIC, CHEMISTRY, &c.

INFLAMMATION. See SURGERY and MEDICNE.

INFLECTION, or *point of inflection*, in the higher geometry, is the point where a curve begins to bend a contrary way. See FLEXURE.

To determine the point of inflection in curves, whose semi-ordinates CM, Cm (Pl. LXXII. Misc. fig. 134) are drawn from the fixed point C; suppose CM to be infinitely near Cm, and make mH = Mm; let Tm touch the curve in M. Now the angle CmT, CMm, are equal; and so the angle CmH, while the semi-ordinates increase, does decrease, if the curve is concave towards the centre C, and increases if the convexity turns towards it. Whence this angle, or, which is the same, its measure, will be a minimum or maximum, if the curve has a point of inflection or retrogression; and so may be found, if the arch TH, or fluxion of it, be made equal to 0, or infinity. And in order to find the arch TH, draw mL, so that the angle TmL be equal to mCL; then if CM $= y$, $mr = x$, mT $= \dot{t}$, we shall have $y : \dot{x} :: \dot{t} : \frac{\dot{t}\dot{x}}{y}$. Again, draw the arch HO to the radius CH; then the small right lines mr, OH, are parallel; and so the triangles OLH, mLr, are similar; but because HI is also perpendicular to mL, the triangles LHI, mLr, are also similar: whence $\dot{t} : \dot{x} :: y : \frac{\dot{x}\ddot{y}}{\dot{t}}$; that is, the quantities mT, mL, are equal. But HL is the fluxion of Hr, which is the distance of C$m = y$; and HD is a negative quantity, because while the ordinate CM increases, their difference rH decreases; whence $\dot{x}x + \dot{y}y - \dot{y}y = 0$, which is a general equation for finding the point of inflection, or retrogradation. See FLUXIONS.

INFORMATION, in law. An information may be defined an accusation or complaint exhibited against a person for some criminal offence, either immediately against the king, or against a private person, which, from its enormity or dangerous tendency, the public good requires should be restrained and punished. It differs principally from an indictment in this, that an indictment is an accusation found by the oath of 12 men, but an information is only the allegation of the officer who exhibits it. 3 Bac. Abr. 164.

Informations are of two kinds: first, those which are partly at the suit of the king, and partly at the suit of a subject; and, secondly, such as are only in the name of the king: the former are usually brought upon penal statutes, which inflict a penalty on conviction of the offender, one part to the use of the king, and another to the use of the informer; and are called qui tam, or popular actions, only carried on by a criminal instead of a civil process.

Informations that are exhibited in the name of the king alone are also of two kinds: first, those which are truly and properly his own suits, and filled ex officio by his own immediate officer, the attorney-general; secondly, those in which, though the king is the nominal prosecutor, yet it is at the relation of some private person, or common informer; and they are filed by the master of the crown office, under the express direction of the court. The objects of the king's own prosecutions, filed ex officio by the attorney-general, are properly such enormous misdemeanours as peculiarly tend to disturb or endanger the government. The objects of the other species of informations, filed by the master of the crown office, upon the complaint or relation of a private subject, are any gross and notorious misdemeanors, riots, batteries, libels, or other immoralities, of an atrocious kind, not peculiarly tending to disturb the government, but which, on account of their magnitude or pernicious example, deserve the most public animadversion. And when an information is filed either thus, or by the attorney-general ex officio, it must be tried by a petty jury of the county where the offence arises; after which, if the defendant is found guilty, he must resort to the court of king's bench for his punishment. 4 Black. 308.

If a common informer should willingly delay his suit, or discontinue, or he non suited, or shall have a verdict or judgment against him, he shall pay costs to the defendant. 18 Eliz. c. 5.

And in the court of king's bench, particularly if the defendant shall appear and plead to issue, and the prosecutor shall not at his own costs, within a year after issue joined, procure the same to be tried; or if a verdict pass for the defendant, or the informer procure a noli prosequi to be entered; the said court of king's bench

may award the defendant his costs, unless the judge shall certify that there was a reasonable cause for exhibiting such information; and if the informer shall not, in three months after such costs taxed, and demand made, pay the same, the defendant shall have the benefit of the recognizance, to compel him thereunto. 4 and 5 W. c. 18.

INFRALAPSARIANS, in church history. an appellation given to such predestinarians as think the decrees of God, in regard to the salvation and damnation of mankind, were formed in consequence of Adam's fall.

INFUSION, a method of obtaining the virtues of plants, roots, &c. by steeping them in a hot or cold liquid.

INFUSORIA, in natural history, minute simple animalcules, seldom visible to the naked eye. When water is examined with the microscope, particularly that which has long been stagnant, and has vegetable matter growing in it, or water in which vegetables have been infused, thousands of minute animals have been discovered, which have been arranged together in this order. When wheat that is rickety is infused in water, small eel-shaped worms are discovered, which were the cause of the disease. Wheat thus injured is very different from smutty wheat. The grains are brown, shrivelled, and of irregular forms; each contains one or more of these worms, which lie dormant as long as the grain is dry; but as soon as it is moistened by being sown, or otherwise, the worms are revivified, feed on the flour, and lay their eggs. If such grain vegetates, the young as soon as they are hatched, eat their way up the stem, and bury themselves in the young succulent ear.

INGRESS, in astronomy, signifies the sun's entering the first scruple of one of the four cardinal signs, especially Aries.

INGROSSER. See FORESTALLING.

INHALER, in medicine, a machine for steaming the lungs with warm water, recommended by Mr. Mudge in the cure of the catarrhous cough. The body of the instrument resembles a porter-pot, holds about a pint, and the handle, which is fixed to the side of it, is hollow. In the lower part of the vessel, where it is soldered to the handle, is a hole, by means of which and three others on the upper part of the handle, the water, when it is poured into the inhaler, will rise to the same level in both. To the middle of the cover a flexible leathern tube, about six or seven inches long, is fixed, with a mouth-piece of wood or ivory. In the cover there is a valve fixed, which opens and shuts the communication between the upper and internal part of the inhaler and external air. This valve is extremely simple: being formed only of a short tube descending inwards from the cover, and having beneath a small hole upon which a ball of cork plays. When the mouth is applied to the end of the tube in the act of inspiration, the air rushes into the handle, and up through the body of warm water, and the lungs become, consequently, filled with hot vapour. In exspiration, the mouth being still fixed to the tube, the breath, together with the steam on the surface of the water in the inhaler, is forced up through the valve in the cover.

INHERITANCE, is a perpetuity in lands or tenements to a man and his heirs; and the word inheritance is not only intended where a man has lands or tenements by descent, but also every fee-simple, or fee-tail, which a person has by purchase, may be said to be an inheritance, because his heirs may inherit it. Lit. s. 9.

Inheritances are corporeal or incorporeal. Corporeal inheritances relate to houses and lands, which may be touched or handled; and incorporeal hereditaments are rights issuing out of, annexed to, or exercised with, corporeal inheritances; as advowsons, tithes, annuities, offices, commons, franchises, privileges, and services. 1 Inst. 49.

There are several rules of inheritances of lands, according to which estates are transmitted from ancestor to heir, viz. 1. That inheritances shall lineally descend to the issue of the person last actually seized, in infinitum, but shall never lineally ascend. 2. The male issue shall be admitted before the female. 3. Where there are two or more males in equal degree the eldest only shall inherit; but the females all together. 4. The lineal descendants, in infinitum, of any person deceased shall represent their ancestor; that is, shall stand in the same place as the person himself would have done had he been living: thus the child, grandchild, or great-grandchild (either male or female), of the eldest son, succeeds before the younger son, and so infinitum. 5. On failure of issue of the person last seized, the inheritance shall descend to the blood of the first purchaser. 6. The collateral heir of the person last seized must be his next collateral kinsman of the whole blood. 7. In collateral inheritances the male stocks shall be preferred to the female, unless where lands are descended from a female: thus the relations on the father's side are admitted in infinitum before those on the mother's side are admitted at all; and the relations of the father's father before those of the father's mother, and so on. 2 Black. c. 14.

INHIBITION, a writ to inhibit or forbid a judge from farther proceedings in the cause depending before him. F. N. B. 39.

INJUNCTION. An injunction is a prohibitory writ, restraining a person from committing or doing a thing which appears to be against equity and conscience. 3 Bac. Abr. 172.

An injunction is usually granted for the purpose of preserving property in dispute pending a suit; as to restrain the defendant from proceedings at the common law against the plaintiff, or from committing waste, or doing any injurious act. Milf. Treat. Chan. Plead.

Injunctions issue out of the courts of equity in several instances. The most usual injunction is to stay proceedings at law; as, if one man brings an action at law against another, and a bill is brought to be relieved either against a penalty, or to stay proceedings at law, or some equitable circumstances, of which the party cannot have the benefit at law. In such case the plaintiff in equity may move for an injunction either upon an attachment, or praying a dedimus, or praying a farther time to answer; for it being suggested in the bill that the suit is against conscience, if the defendant is in contempt for not answering, or prays time to answer, it is contrary to conscience to proceed at law in the mean time; and therefore an injunction is granted of course: but this injunction only stays execution touching the matter in question; and there is always a clause giving liberty to call for a plea to proceed to trial, and

for want of it to obtain judgment; but execution is stayed till answer, or farther order. 3 Bac. Abr. 178.

When a bill in chancery is filed in the office of the six clerks, if an injunction is prayed therein, it may be had, at various stages of the cause, according to the circumstances of the case. If the bill is to stay execution upon an oppressive judgment, and the defendant does not put in his answer within the time allowed by the rules of the court, an injunction will issue of course; and when the answer comes in, the injunction can only be continued upon a sufficient ground appearing from the answer itself. But if an injunction is wanted to stay waste, or other injuries of an equally unjust nature, then upon the filing of the bill, and a proper case supported by affidavits, the court will grant an injunction immediately; to continue till the defendant has put in his answer, and till the court shall make some further order concerning it; and when the answer comes in whether it shall then be dissolved, or continued till the hearing of the cause, is determined by the court upon argument, drawn from considering the answer and affidavits together. 3 Bla. 443.

The method of dissolving injunctions are various; when the answer comes in, and the party has cleared his contempt by paying the costs of the attachment, if there is one, he obtains an order to dissolve nisi, and serves it on the plaintiff's clerk in court: this order takes notice of the defendant's having fully answered the bill, and thereby denied the full equity thereof, and being regularly served, the plaintiff must show cause at the day; or the defendant's counsel, where there is no probability of showing cause, may move to make the order absolute, unless cause, sitting the court. 3 Bac. Abr. 177.

If the plaintiff who has an injunction die pending the suit, in strictness the whole proceedings are abated, and the injunction with them; but even in this case the party shall not take out execution without special leave of the court; he must move the court for the plaintiff to revive his suit within a limited time, or the injunction to stand dissolved; and as this is never denied, so if the suit is not revived, the party takes out execution. There are some instances where a plaintiff may move to revive his injunction; but as that rarely happens, so it is rarely granted, especially where the injunction has been before dissolved; but where a bill is dismissed, the injunction and every thing else are gone, and execution may be taken out the next day. 3 Bac. Abr. 178.

INJURY, a wrong or damage to a man's person or goods. The law will suffer a private injury rather than a public evil; and the act of God or the law does injury to none. 4 Rep. 124.

INK. There are two principal kinds of ink, writing and printing ink.

Writing-ink. When to an infusion of gall-nuts some solution of sulphate of iron (green copperas) is added, a very dark blue precipitate takes place. This precipitate is the gallic acid of the galls united to the iron of the green vitriol, forming gallat of iron, which is the basis of writing-ink. If galls and sulphate of iron only were used, the precipitate would fall down, leaving the water colourless; and in order to keep it suspended in the water, forming a permanently black, or rather a very dark blue fluid, gum arabic is added, which, by its viscid nature, prevents the precipitate from falling down.

Various receipts have been given for the composition of writing-ink, but very few have been founded upon a knowledge of its real nature. The receipt given by M. Rihancourt is as follows: Take eight ounces of Aleppo galls, in coarse powder; four ounces of logwood, in thin chips; four ounces of sulphate of iron (green copperas); three ounces of gum arabic in powder; one ounce of sulphate of copper (blue vitriol); and one ounce of sugar-candy. Boil the galls and logwood together in twelve pounds of water for one hour, or till half the liquid has been evaporated. Strain the decoction through a hair sieve, or linen cloth, and then add the other ingredients. Stir the mixture till the whole is dissolved, more especially the gum; after which leave it to subside for 24 hours. Then decant the ink, and preserve it in bottles of glass or stone ware, well corked.

The following will also make a good ink: To one quart of soft water add four ounces of galls, one ounce of copperas roughly bruised, and two ounces of gum arabic. Let the whole be kept near the fire a few days, and occasionally well shaken.

Red writing-ink is made in the following manner: Take of the raspings of Brazil wood a quarter of a pound, and infuse them two or three days in vinegar. Boil the infusion for an hour over a gentle fire, and afterwards filtre it while hot. Put it again over the fire, and dissolve in it, first, half an ounce of gum arabic; and afterwards of alum and white sugar, each half an ounce.

Printing-ink is a black paint, composed of lampblack and linseed or suet oil boiled, so as to acquire considerable consistence and tenacity. The art of preparing it is kept a secret; but the obtaining good lampblack appears to be the chief difficulty in making it.

The ink used by copper-plate printers differs from the last only in the oil not being so much boiled, and the black which is used being Frankford black.

Sympathetic inks are such as do not appear after they are written with, but which may be made to appear at pleasure, by certain means to be used for that purpose. A variety of substances have been used for this purpose. We shall describe the best of them.

1. Dissolve some sugar of lead in water, and write with the solution. When dry, no writing will be visible. When you want to make it appear, wet the paper with a solution of alkaline sulphuret (liver of sulphur), and the letters will immediately appear of a brown colour. Even exposing the writing to the vapours of these solutions will render it apparent.

2. Write with a solution of gold in aqua regia, and let the paper dry gently in the shade. Nothing will appear; but draw a sponge over it wetted with a solution of tin in aqua regia, the writing will immediately appear of a purple colour.

3. Write with an infusion of galls, and when you wish the writing to appear, dip it into a solution of green vitriol; the letters will appear black.

4. Write with distilled sulphuric acid, and nothing will be visible. To render it so, hold it to the fire, and the letters will instantly appear black.

5. Juice of lemons, or onions, a solution of sal ammo-

niac, green vitriol, &c. will answer the same purpose, though not so easily, nor with so little heat.

6. Green sympathetic ink. Dissolve cobalt in nitro-muriatic acid, and write with the solution. The letters will be invisible till held to the fire, when they will appear green, and will disappear completely again when removed into the cold. In this manner they may be made to appear and disappear at pleasure.

A very pleasant experiment of this kind is to make a drawing representing a winter scene, in which the trees appear void of leaves, and to put the leaves on with this sympathetic ink; then, upon holding the drawing near to the fire, the leaves will begin to appear in all the verdure of spring, and will very much surprise those who are not in the secret.

7. Blue sympathetic ink. Dissolve cobalt in nitric acid; precipitate the cobalt by potass; dissolve this precipitated oxide of cobalt in acetic acid, and add to the solution one-eighth of common salt. This will form a sympathetic ink, that, when cold, will be invisible, but will appear blue by heat.

INK, *removing stains of.* The stains of ink on cloth, paper, or wood, may be removed by almost all acids; but those acids are to be preferred which are least likely to injure the texture of the stained substance. The muriatic acid, diluted with five or six times its weight of water, may be applied to the spot, and, after a minute or two, may be washed off, repeating the application as often as may be found necessary. But the vegetable acids are attended with less risk, and are equally effectual. A solution of the oxalic, citric (acid of lemons), or tartareous acids, in water, may be applied to the most delicate fabrics without any danger of injuring them; and the same solutions will discharge writing, but not printing-ink. Hence they may be employed in cleaning books which have been defaced by writing on the margin, without impairing the text. Lemon-juice, and the juice of sorrel, will also remove ink-stains, but not so easily as the concrete acid of lemons, or citric acid.

INNS AND INNKEEPES. Common inns were instituted for passengers; and the duty of inkeepers extends chiefly to the entertaining and harbouring of travellers, finding them victuals and lodging, and securing the goods and effects of their guests; and therefore if one who keeps a common inn refuses either to receive a traveller as a guest into his house, or to find him victuals or lodging, upon his tendering a reasonable price for the same, he is not only liable to render damages for the injury in an action on the case, at the suit of the party grieved, but also may be indicted and fined at the suit of the king. Dyer, 158.

In return for such responsibility the law allows him to retain the horse of his guest until paid for his keep; but he cannot retain such horse for the bill of the owner, although he may retain his goods for such bill; neither can he detain one horse for the food of another. 1 Bulst. 207, 217.

An innkeeper, however, is not bound to receive the horse, unless the master lodge there also. 2 Brown, 254.

Neither is a landlord bound to furnish provisions unless paid beforehand. 9 Co. 87.

If an innkeeper makes out unreasonable bills, he may be indicted for extortion; and if either he or any of his servants knowingly sell bad wine or bad provisions, they will be responsible in an action of deceit.

Any person may set up a new inn, unless it is inconvenient to the public, in respect of its situation, or to its increasing the number of inns, not only to the prejudice of other ancient and well-governed inns: for the keeping of an inn is no franchise, but a lawful trade, open to every subject, and therefore there is no need of any licence from the king for that purpose. 2 Roll. Abr. 84.

An innkeeper is distinguished from other trades in that he cannot be a bankrupt; for though he buys provisions to be spent in his house, yet he does not properly sell them, but utter them at such rates as he thinks reasonable; and the attendance of his servants, furniture of his house, &c. are to be considered; and the statutes of bankruptcy only mention merchants that use to buy and sell in gross, or buy retail, and such as get their living by buying and selling; but the contracts with innkeepers are not for any commodities in specie, but they are contracts for house-room, trouble, attendance, lodging, and necessaries, and therefore cannot come within the design of such words, since there is no trade carried on by buying and bartering commodities. 1 Jones, 437.

But where an innkeeper is a chapman also, and buys and sells, he may, on that account, be a bankrupt, though not barely as an innkeeper, and this has been frequently seen. 7 Vin. Abr. 57.

Innkeepers are clearly chargeable for the goods of guests stolen or lost out of their inns, and this without any contract or agreement for that purpose; for the law makes them liable in respect of the reward, as also in respect of their being places appointed and allowed by law, for the benefit and security of traders and travellers. Dyer, 266.

But if a person comes to an innkeeper, and desires to be entertained by him, which the inkeeper refuses, because his house is already full; whereupon the party says he will shift among the rest of his guests, and there he is robbed, the host shall not be charged. Dyer, 158.

If a man comes to a common inn to harbour, and desires that his horse may be put to grass, and the host put him to grass accordingly, and the horse is stolen, the host shall not be charged; because by law the host is not bound to answer for any thing out of his inn, but only for those that are infra hospitium. 8 Co. 32 b.

Innkeepers may detain the person of the guest who eats, or the horse which eats, till payment, and this he may do without any agreement for that purpose; for men that get their livelihood by entertainment of others, cannot annex such disobliging conditions, that they should retain the party's property in case of non-payment, nor make such disadvantageous and impudent a supposition, that they shall not be paid; and therefore the law annexed such a condition without the agreement of the parties. Roll. Abr. 85.

By the custom of London and Exeter, if a man commits a horse to a hostler, and he eats out the price of his head, the hostler may take him as his own, upon the reasonable appraisement of four of his neighbours; but the innkeeper has no power to sell the horse, by the general custom of the whole kingdom. Moor. 876. 3 Bulst. 271.

But it has been held, that though an innkeeper in

London may, after long keeping, have the horse appraised, and sell him; yet when he has, in such case, had him appraised, he cannot justify the taking him to himself, at the price it was appraised at. 1 Vin. Abr. 233.

INNS OF COURT, are so called, because the students therein study the law, to enable them to practise in the courts at Westminster, or elsewhere; and also because they use all other gentle exercises, as may render them better qualified to serve the king in his court. Fortesq. c. 49.

INNOMINATA OSSA. See ANATOMY.

INNUENDO, is a word used in declarations and law proceedings, to ascertain a person or thing which was named before; as to say he (innuendo the plaintiff) did so and so, when there was mention before of another person.

Innuendo may serve for an explanation where there is precedent matter, but never for a new charge; it may apply what is already expressed, but cannot add or enlarge the importance of it. 2 Salk. 513.

INOCULATION. See MEDICINE.

INOCULATION, or *Budding*. See GRAFTING.

INOLITHUS, in mineralogy, a stone consisting of carbonate of lime, carbonic acid gas, and a little iron; entirely soluble in nitric acid with effervescence; fibrous, parasitic, soft, lightish, breaking into indeterminate fragments. There are several species: of the filamentosius there are three varieties; the satin spar, so called from its rich satiny lustre, is found in Russia, Poland, Germany, Saxony, and Bohemia, with the fibres straight and a little curved. It is found also about a mile from Alston in Cumberland, washed by the river Tyne, near the level of its bed; colour white, with sometimes a rosy tinge from a diluted oxide of iron, and transmits light from the edges, or in thinner pieces: fracture in the direction of the striæ fibrous, straight or curved; specific gravity about 2.71, contains carbonic acid 47, carbonate of lime 50, water crystallization 2, and a small portion of iron.

INORDINATE PROPORTION, is where there are three magnitudes in one rank, and three others proportional to them in another, and you compare them in a different order. Thus suppose the numbers in one rank to be 2, 3, 9; and those of the other rank 8, 24, 36; which are compared in a different order, viz. 2 : 3 : : 24 : 36; and 3 : 9 : : 8 : 24. Then rejecting the mean terms of each rank, you conclude 2 : 9 : : 8 : 36.

INQUEST, in law, signifies an inquiry made by a jury, in a civil or criminal cause, by examining witnesses. There is also an inquest of office, used for the satisfaction of the judges, and sometimes to make an inquiry, whether a criminal is a lunatic or not; upon which inquest, if it is found that the criminal only feigns himself to be a lunatic, and at the same time refuses to plead, he may be dealt with as one standing mute. Where a person is attainted of felony, and escapes, and afterwards, on being retaken, denies that he is the same man, inquest must be made into the identity of the person by a jury, before he can be executed.

INQUISITION, in law, a manner of proceeding by way of search or examination used on the king's behalf, in cases of outlawry, treason, felony, self-murder, &c. to discover lands, goods, and the like, forfeited to the crown. Inquisition is also had upon extents of lands, tenaments, &c. writs of elegit, and where judgment being had by default, damages and costs are recovered.

INQUISITION, in the church of Rome, a tribunal in several Roman-catholic countries, erected by the popes for the examination and punishment of heretics.

This court was founded in the 12th century by father Dominica and his followers, who were sent by pope Innocent III. with orders to excite the catholic princes and people to extirpate heretics, to search into their number and quality, and to transmit a faithful account thereof to Rome. Hence they were called inquisitors; and this gave birth to the formidable tribunal of the inquisition, which was received in all Italy, and the dominions of Spain, except the kingdom of Naples, and the Lower-countries. See ACT OF FAITH.

INROLLMENT, in law, is the registering, recording, or entering in the rolls of the chancery, king's-bench, common-pleas, or exchequer, or by the clerk of the peace in the records of the quarter-sessions, of any lawful act; a statute of recognizance acknowledges a deed of bargain and sale of lands, and the like; but the inrolling a deed does not make it a record, though it thereby becomes a deed recorded; for there is a difference between a matter of record and a thing recorded to be kept in memory; a record being the entry in parchment of judicial matters controverted in a court of record, and whereof the court takes notice, whereas an inrollment of a deed is a private act of the parties concerned, of which the court takes no cognizance at the time of doing it, although the court permits it. 2 Lill. Abr. c. 9.

By stat. 27 H. VIII. c. 16, no lands shall pass, whereby any estate of inheritance or freehold shall take effect, or any use thereof be made, by reason only of any bargain and sale thereof, except the bargain and sale is made by writing indented, sealed, and within six months inrolled within one of the king's courts of record at Westminster; or else within the county where the lands lie, before the clerk of the peace, and one or more justices.

But by 5 Eliz. c. 26, in the counties palatine, they may be inrolled at the respective courts there, or at the assizes.

Every deed before it is inrolled is to be acknowledged to be the deed of the party, before a master of chancery, or a judge of the court wherein it is inrolled, which is the officer's warrant for inrolling the same; and the inrollment of a deed, if it is acknowledged by the grantor, will be a good proof of the deed itself upon trial. 2 Lill. Abr. 69.

But a deed may be inrolled without the examination of the party himself; for it is sufficient if oath is made of the execution. If two are parties, and the deed is acknowledged by one, the other is bound by it. And if a man lives abroad, and would pass lands in England, a nominal person may be joined with him in the deed, who may acknowledge it here, and it will be binding. 1 Salk. 389.

INSANITY. See MEDICINE.

INSCRIBED, in geometry. A figure is said to be inscribed in another when all its angles touch the sides or planes of the other figure.

INSECTS. See ENTOMOLOGY.

INSOLATION, in chemistry, a term made use of to

denote an exposure to the sun, to promote the chemical action of one substance upon another.

INSTALLMENT, the instating or establishing a person in some dignity. This word is chiefly used for the induction of a dean, prebendary, or other ecclesiastical dignitary, into the possession of his stall, or other proper seat in the cathedral to which he belongs. It is always used for the ceremony whereby the knights of the garter are placed in their rank in the chapel of St. George at Windsor, and on many other like occasions. It is sometimes termed installation.

INSTITUTES, in literary history, a book containing the elements of the Roman law, and constituting the last part of the civil law. The institutes are divided into four books, and contain an abridgment of the whole body of the civil law, being designed for the use of students.

INSTITUTION, in general, signifies the establishing or founding something.

In the canon and common law it signifies the investing a clerk with the spiritualities of a rectory, &c. which is done by the bishop, who uses the formula, "I institute you rector of such a church, with cure of souls, and receive your care and mine." This makes him a complete parson as to spirituality, but not as to temporality, which depends on induction. The term institutions is also used, in a literary sense, for a book containing the elements of any art or science: such are institutions of medicine, institutions of rhetoric, &c.

INSTRUMENT, in law, some public act or authentic deed, by which any truth is made apparent, or any right or title established in a court of justice. See DEED.

INSTRUMENTS, in music, are either played on by means of wind, as the organ, &c.; or by strings, as the violin, &c.

INSTRUMENTS, ASTRONOMICAL. We shall, under the word OBSERVATORY, give an account of the several instruments made use of in practical astronomy.

INSTRUMENTS, *mathematical.* A pocket case of mathematical instruments contains the following particulars, viz. 1. A pair of plain compasses. 2. A pair of drawing compasses, with its several parts. 3. A drawing-pen and pointer. 4. A protractor, in form of a semicircle, or sometimes of a parallelogram. 5. A parallel ruler. 6. A plain scale. 7. A sector, besides the black-lead pencil for drawing lines. The general uses of the above instruments are as follows: see Pl. LXXIII. Mathematical Instruments.

I. *Of the plain compasses,* Fig. 1. The use of the common or plain compasses is, (1.) to draw a blank line A B, by the edge of a ruler, through any other given point or points C D, &c. (2.) Take any extent or length between the points of the compasses, and to set it off, or apply it successively upon any line, as from C to D, fig. 2. (3.) To take any proposed line C D between the points, and, by applying it to the proper scale, to find its length. (4.) To set off equal distances upon a given line, by making a dot with the point at each, through which to draw parallel lines. (5.) To draw any blank circle, intersecting arches, &c. (6.) To lay off an angle of a given quantity upon an arch of a circle from the line of chords, &c. (7.) To measure any arch or angle, upon the chords, &c. (8.) To construct any proposed figure, in plotting or making plans, &c. by setting off the quantity of the sides and angles from proper scales. In short, the use of the compasses occurs in every branch of practical mathematics.

II. *Of the drawing-compasses.* These compasses are chiefly designated for drawing circles, and circular arches; and it is often necessary they should be drawn with different materials; and therefore this pair of compasses has, in one of its legs a triangnal socket, screw, to receive and fasten the following parts or points for that purpose. viz. (1.) A steel point, which being fixed in the socket, makes the compasses then but a plain pair, and has all the same uses as just now described in drawing blank circles, setting off lines, &c. (2.) A port-crayon with a black-lead pencil, cut to a fine point, for drawing lines that may be easily rubbed out again, if not right. A piece of slate-pencil may also be used in this part for drawing on slate. (3.) The dotting-point, or dotting-pen, with a small rowel, or indented wheel at the end, moving very freely; and receiving ink from the brass pen over it, communicates the same in equal and regular dots upon the paper, where dotted lines are chosen. (4.) The steel pen or point, for drawing and describing black lines with ink; for this purpose the two parts or sides of the pen are opened or closed with an adjusting screw, that the line drawn may be as fine or as coarse as you please.

In the port-crayon, dotter, and steel pen, there is a joint, by which you can set the lower part always perpendicular to the paper, which is necessary for drawing a line well, in every extent or opening of the compasses.

In some of the better sort of instruments, these points slide into the socket, and are kept tight by a spring on the inside that is not seen.

The steel point is sometimes made with a joint, and furnished with a fine spring and screw; by which, when you have opened the compasses nearly to the extent required, you can, by turning the screw, move the point to the true extent as it were, to a hair's breadth; which is the reason these are called hair-compasses.

The common compasses, at large, are not altogether so well adapted for small drawings; and therefore a small sort called bows, are contrived to answer all such purposes; they consist only of a steel point and drawing-pen, with a joint, and of a small length, so that very small circles may be nicely drawn with them, as they are to be conveniently moved and turned about in the hand, by a short stem or shaft.

III. *Of the drawing pen and pencil.* The drawing-pen is only the common steel pen at the end of a brass rod, or shaft, of a convenient length, to be held in the hand for drawing all kinds of straight black lines by the edge of a rule. The shaft or handle has a screw in the middle part; and, when unscrewed, there is a fine steel round pin or point, by which you make as nice a mark or dot upon the paper as you please, for terminating your lines in curious draughts.

The black-lead pencil, if good, is of frequent use for drawing straight lines, and for supplying the place of the drawing-pen, where lines of ink are not necessary; it is also often substituted for the common pen in writing, figuring, &c. Because in all cases, if what be drawn with it be not right, or does not please, it may be very easily rubbed out with a piece of crumb-bread, or indian rubber, and the whole new-drawn.

IV. *Of the protractor.* The protractor is a semicircle of brass, ADB, divided into 180 degrees, and numbered each way from end to end of the semicircle by 10°, 20°, 30°, &c. The central line is the external edge of the protractor's diameter, or straight side, sloped down to the under side, and is generally called a fiducial edge; in the middle of which is a small line or fine notch in the very edge, for the centre of the protractor. The uses of the protractor are two: (1.) To measure any angle proposed. (2.) To lay down any angle required.

For example: suppose it required to find what number of degrees are contained in the angle ACB (fig. 4); you place the centre of the protractor upon the angular point C, and the fiducial edge exactly upon the line CA; then observe what number of degrees the line CB cuts upon the graduated limb of the protractor, and that will be the measure of the angle ACB as required.

Secondly, suppose it required to protract or lay off from the line AC, an angle ACB, equal to 35 degrees. To do this, you place the centre of the protractor upon the given point C, and the straight edge upon AC very exactly; then make a fine point or dot at 35 degrees on the limb at B, and the protractor being removed, you draw through B the straight line CB, and it will make the angle ACB required.

Protractors in form of a parallelogram, or long square, as *a* E F *b* fig. 3, are usually made in ivory or brass; are more exact than the common semicircular ones, for angles to 40 or 50 degrees, because at and about each end, the divisions (being farther from the centre) are larger.

V. *Of the parallel ruler.* The parallel ruler is so called, because as it consists of two straight rules, connected together by two brass bars, yet so as to admit a very free motion to each: the one rule must always move parallel-wise to the other, that is, one rule will be every where equidistant from the other, and by this means it becomes naturally fitted for drawing one or more lines parallel to, or equally distant from, any line proposed. The manner of doing which is thus:

Let it be required to draw a straight line parallel to a given line AB, and at the distance AC, from it. (fig. 5.) First open the rulers to a greater distance than AC, and place the edge of the rulers exactly on the line AB; then holding the other rule (or side) firmly on the paper, you move the upper rule down from A to the point C, by which (holding it fast) you draw the line CD, which will be parallel to the given line AB as required.

Many very useful problems in the mathematics are performed by this instrument, of which the following are examples.

Let it be required to find a fourth proportional to three right lines given, AB, BC, and AD (fig. 6). To do this, draw the lines AC, AE, making any angle at pleasure. Upon AC with the compasses set off the lines AB and BC; and upon AE set off the line AD; join DB, and parallel to it draw EC, then will DE be the fourth proportional required. For AB : BC : : AD : DE.

Again, suppose it required to divide any line, AB, as another line AC is divided (fig. 7). To do this, join the extremities of each line CB, and parallel to CB draw EI, EH, DG, through the given points DEF in the line AC; and by these lines the line AB will be divided exactly similar to the line AC.

The parallel ruler is seldom put into a case of instruments, but those of the larger and better sort; being generally sold by itself of various sizes, from 6 inches to 2 feet in length.

Of the plain scale. The lines generally drawn on the plain scale, are these following:

		Marked
I.	Lines of equal parts.	E. P.
II.	——— Chords.	Cho.
III.	——— Rhumbs.	Ru.
IV.	——— Sines.	Sin.
V.	——— Tangents.	Tan.
VI.	——— Secants.	Sec.
VII.	——— Half Tangents.	S. T.
VIII.	——— Longitude.	Long.
IX.	——— Latitude.	Lat.
X.	——— Hours.	Ho.
XI.	——— Inclinations.	In. Mer.

Of the lines of equal parts. Lines of equal parts are of two sorts, viz. simply divided, and diagonally divided.

1. Simply divided. Draw three lines parallel to one another, at unequal distances (fig. 8), and of any convenient length; divide this length into what number of equal parts is thought necessary, allowing some certain number of these parts to an inch, such as 2, $2\frac{1}{2}$, 3, $3\frac{1}{2}$, 4, $4\frac{1}{2}$, &c. which divisions distinguish by lines drawn across the three parallels. Divide the left-hand division into 10 equal parts, which distinguish by lines drawn across the lower parallels only; but for distinction's sake, let the fifth division be somewhat longer than the others: and it may not be inconvenient to divide the same left hand division into 12 equal parts, which are laid down on the upper parallel line, having the third, sixth, and ninth divisions distinguished by longer strokes than the rest, whereof that at the sixth division make the longest.

There are, for the most part, several of these simply divided scales put on rulers, one above the other, with numbers on the left hand, showing in each scale, how many equal parts an inch is divided into; such as 20, 25, 30, 35, 40, 45, &c. and are severally used, as the plan to be expressed should be larger or smaller.

The use of these lines of equal parts, is to lay down any line expressed by a number of two places or denominations, whether decimally or duodecimally divided; as leagues, miles, chains, poles, yards, feet, inches, &c. and their tenth parts, or twelfth parts; thus, if each of the divisions be reckoned 1, as 1 league, mile, chain, &c. then each of the subdivisions will express $\frac{1}{10}$ part thereof; and if each of the large divisions be called 10, then each small one will be 1; and if the large divisions be 100, then each small one will be 10, &c.

Therefore to lay off a line $8\frac{7}{10}$, 87, or 870 parts, let them be leagues, miles, chains, &c. set one point of the compasses on the 8th of the large divisions, counting from the left hand towards the right, and open the compasses, till the other point falls on the 7th of the small divisions, counting from the right hand toward the left, then are the compasses opened to express a line of $8\frac{7}{10}$ 87, or 870 leagues, miles, chains, &c. and bears such proportion in the plan, as the line measured does to the thing represented.

But if a length of feet and inches was to be expressed, the same large divisions may represent the feet, but the

inches must be taken from the upper part of the first division, which (as before noted) is divided into twelve equal parts.

Thus if a line of 7 feet 5 inches was to be laid down, set one point of the compass on the fifth division among the twelve, counting from the right hand towards the left, and extend the other to 7, among the large divisions: and that distance laid down in the plan, shall express a line of 7 feet 5 inches; and the like is to be understood of any other dimensions.

2. Diagonally divided. Draw eleven lines parallel to each other, and at equal distances; divide the upper of these lines into such a number of equal parts, as the scale to be expressed is intended to contain; and from each of these divisions draw perpendiculars through the eleven perallels (fig. 9): subdivide the first of these divisions into 10 equal parts, both in the upper and lower lines; then each of these subdivisions may be also subdivided into ten equal parts, by drawing diagonal lines; viz. from the 10th below, to the ninth above; from the ninth below to the eighth above; from the eighth below to the seventh above, &c. till from the first below to the 10th above, so that by these means one of the primary divisions on the scale will be divided into 100 equal parts.

There are generally two diagonal scales laid on the same plane or face of the ruler, one being commonly half the other (fig. 9.)

The use of the diagonal scale is much the same with the simple scale; all the difference is, that a plan may be laid down more accurately by it; because in this, a line may be taken of three denominations, whereas from the former, only two could be taken.

Now from this construction it is plain, if each of the primary divisions represent 1, each of the first subdivisions will express $\frac{1}{10}$ of 1; and each of the second subdivisions (which are taken on the diagonal lines, counting from the top downwards) will express $\frac{1}{10}$ of the former subdivisions or 100th of the primary divisions; and if each of the primary divisions express 10, then each of the first subdivisions will express 1, and each of the 2d, $\frac{1}{10}$; and if each of the primary divisions represent 100, then each of the first subdivisions will be 10, and each of the 2d will be 1, &c.

Therefore to lay down a line, whose length is expressed by 347, $34\frac{7}{10}$ or $3\frac{47}{100}$, whether leagues, miles, chains, &c.

On the diagonal line, joined to the 4th of the first subdivisions, count 7 downwards, reckoning the distance of each parallel 1; there set one point of the compass, and extend the other, till it falls on the intersection of the third primary division with the same parallel in which the other foot rests, and the compasses will then be opened to express a line of 347, $34\frac{7}{10}$, or $3\frac{47}{100}$, &c.

Those who have frequent occasion to use scales, perhaps will find, that a ruler with the 20 following scales on it, viz. 10 on each face, will suit more purposes than any set of simply divided scales hitherto made public, on one ruler.

One side.—The divisions to an inch.
10, 11, 12, $13\frac{1}{2}$, 15, $16\frac{1}{2}$, 18, 20, 22, 25.
Other side.—The divisions to an inch.
28, 32, 36, 40, 45, 50, 60, 70, 85, 100.

The left-hand primary division, to be divided into 10 and 12 and 8 parts; for these subdivisions are of great use in drawing the parts of a fortress, and of a piece of cannon.

It will here be convenient to show, how any plan expressed by right lines and angles, may be delineated by the scales of equal parts, and the protractor. Suppose three adjacent things in any right-lined triangle being given, to form the plan thereof.

Example. Let ABC (fig. 10,) be a triangular field, the side AB = 327 yards; AC = 208 yards; and the angle at A = $44\frac{1}{2}$ degrees.

Construction. Draw a line AB at pleasure; then from the diagonal scale take 327 between the points of the compasses, and lay it from A to B; set the centre of the protractor to the point A, lay off $44\frac{1}{2}$ degrees, and by that mark draw AC; take with the compasses from the same scale 208, lay it from A to C, and join C B; so shall the parts of the triangle A B C, in the plan, bear the same proportion to each other, as the real parts in the field do.

The side C B may be measured on the same scale from which the sides A B, A C, were taken; and the angles at B and C may be measured by applying the protractor to them.

If two angles and the side contained between them were given.

Draw a line to express the side (as before); at the ends of that line, point off the angles, as observed in the field; lines drawn from the ends of the given line through those marks, shall form a triangle similar to that of the field.

Five adjacent things, sides and angles, in a right-lined quadrilateral, being given, to lay down the plan thereof, fig. 11.

Example. Given $\angle$ A = 70°; AB = 215 links; $\angle$ B = 115°; BC = 596 links; $\angle$ C = 114°.

Construction. Draw A D at pleasure; from A draw A B, so as to make with A D an angle of 70°: make AB = 215 (taken from the scales); from B, draw B C, to make with A B an angle of 115°; make B C = 596; from C, draw C D, to make with C B an angle of 114°; and by the intersection of C D with A D, a quadrilateral will be formed similar to the figure in which such measures could be taken as are expressed in the example.

If three of the things were sides, the plan might be formed with equal ease.

Following the same method, a figure of many more sides may be delineated; and in this manner, or some other like to it, surveyors make their plans or surveys.

The remaining lines of the plain scale are thus constructed.

Describe a circumference with any convenient radius, and draw the diameters fig. 12 A B, D E, at right angles to each other; continue B A at pleasure towards F; through D, draw D G parallel to B F; and draw the chords B D, B E, A D, A E. Circumscribe the circle with the square H M N, whose sides H M, M N, shall be parallel to AB, E D.

1. *To construct the line of chords.* Divide the arc A D into 90 equal parts: mark the 10th divisions with the figures 10, 20, 30, 40, 50, 60, 70, 80, 90; on D, as a

centre, with the compasses, transfer the several divisions of the quadrantal arc, to the chord A D, which marked with the figures corresponding, will become a line of chords.

Note. In the construction of this, and the following scales, only the primary divisions are drawn; the intermediate ones are omitted, that the figure may not appear too much crowded.

2. *The line of rhumbs.* Divide the arc B E into 8 equal parts, which mark with the figures 1, 2, 3, 4, 5, 6, 7, 8, and divide each of those parts into quarters; on B, as a centre, transfer the divisions of the arc to the chord B E, which marked with the corresponding figures, will be a line of rhumbs.

3. *The line of sines.* Through each of the divisions of the arc A D, draw right lines parallel to the radius A C; and C D will be divided into a line of sines which are to be numbered from C to D for the right sines, and from D to C for the versed sines. The versed sines may be continued to 180 degrees by laying the divisions of the radius C D, from C to E.

4. *The line of tangents.* A ruler on C, and the several divisions of the arc A D, will intersect the line D G, which will become a line of tangents, and is to be figured from D to G, with 10, 20, 30, 40, &c.

5. *The line of secants.* The distances from the centre C to the divisions on the line of tangents being transferred to the line C F from the centre C, will give the divisions of the line of secants; which must be numbered from A towards F, with 10, 20, 30, &c.

6. *The line of half tangents (or the tangents of half the arcs.)* A ruler on E, and the several divisions of the arc A D, will intersect the radius C A, in the divisions of the semi or half tangents; mark these with the corresponding figures of the arc A D.

The semitangents on the plane scales are generally continued as far as the length of the ruler they are laid on will admit; the divisions beyond 90° are found by dividing the arc A E like the arc A D, then laying a ruler by E and these divisions of the arc A E, the divisions of the semitangents above 90 degrees will be obtained on the line C A continued.

7. *The line of longitude.* Divide A H into 60 equal parts; through each of these divisions, parallels to the radius A C, will intersect the arc A E, in as many points; from E as a centre, the divisions of the arc E A, being transferred to the chord E A, will give the divisions of the line of longitude.

The points thus found on the quadrantal arc, taken from A to E, belong to the sines of the equally increasing sexagenary parts of the radius; and those arcs reckoned from E, belong to the cosines of those sexagenary parts.

8. *The line of latitude.* A ruler on A, and the several divisions of the sines on C D, will intersect the arc BD, in as many points; on B as a centre, transfer the intersections of the arc B D, to the right line B D; number the divisions from B to D, with 10, 20, 30, &c. to 90; and B D will be a line of latitude.

9. *The line of hours.* Bisect the quadrantal arcs B D, B E, in a, b; divide the quadrantal arc ab into 6 equal parts (which gives 15 degrees for each hour), and each of these into 4 others (which will give the quarters). A ruler on C, and the several divisions of the arc ab, will intersect the line MN in the hour, &c. points which are to be marked as in the figure.

10. *The line of inclinations of meridians.* Bisect the arc E A in c; divide the quadrantal arc bc into 90 equal parts; lay a ruler on C and the several divisions of the arc bc, and the intersections of the line HM will be the divisions of a line of inclinations of meridians.

Of the sector. A sector is a figure formed by two radii of a circle, and that part of the circumference comprehended between the two radii.

The instrument called a sector, consists of two flat rulers moveable round an axis or joint; and from the centre of this joint several scales are drawn on the faces of the rulers.

The two rulers are called legs, and represent the radii of a circle; and the middle of the joint expresses the centre.

The scales generally put on sectors, may be distinguished into single, and double.

The single scales are such as are commonly put on plain scales, and from whence dimensions or distances are taken, as have been already directed.

The double scales are those which proceed from the centre; each scale is laid twice on the same face of the instrument, viz. once on each leg: from these scales, dimensions or distances are to be taken, when the legs of the instrument are in an angular position, as will be shown hereafter.

The SCALES *commonly put on the best* SECTORS *are,*

Single	1	a line of	Iches, each Inch divided into 8 and 10 parts.		
	2		Decimals, containing 100 parts.		
	3		Chords,	marked	Cho.
	4		Sines,		Sin.
	5		Tangents,		Tang.
	6		Rhumbs,		Rum.
	7		Latitude,		Lat.
	8		Hours,		Hou.
	9		Longitude,		Lon.
	10		Inclin. Merid.		In. Me.
	11		the Logarithms of Numbers,		Num.
	12		the Logarithms of Sines,		Sin.
	13		the Logarithms of Versed Sines,		V. Sin.
	14		the Logarithms of Tangents,		Tan.

Double	1	a line o	Lines, or of equal parts,	marked	Lin.
	2		Chords,		Cho.
	3		Sines,		Sin.
	4		Tangents to 45°,		Tan.
	5		Secants,		Sec.
	6		Tangents above 45°,		Tan.
	7		Polygons,		Pol.

The scales of lines, chords, sines, tangents, rhumbs, latitudes, hours, longitude, incl. merid. may be used, whether the instrument is shut or open, each of these scales being contained on one of the legs only. The scales of inches, decimals, log. numbers, log. sines, log. versed sines, and log. tangents, are to be used with the sector quite opened, part of each scale lying on both legs.

The double scales of lines, chords, sines, and lower tangents, or tangents under 45 degrees, are all of the same radius or length; they begin at the centre of the instrument, and are terminated near the other extremity of each leg; viz. the lines at the division 10, the chords at 60, the sines at 90, and the tangents at 45; the remainder of the tangents, or those above 45 degrees, are on other scales beginning at $\frac{1}{4}$ of the length of the former, counted from the centre, where they are marked with 45, and run to about 76°.

The secants also begin at the same distance from the centre, where they are marked with 0, and are from thence continued to as many degrees as the length of the sector will allow, which is about 75 degrees.

Each double scale, one being on each leg and proceeding from the centre, make an angle; and in an equal angular position are all the double scales, whether of lines, or of chords, or of sines, or of tangents to 45 degrees.

And the angles made by the scales of upper tangents, and of secants, are also equal; and sometimes these angles are made equal to those made by the other double scales.

The scales of polygons are put near the inner edge of the legs: their beginning is not so far removed from the centre, as the 60 on the chords is: where these scales begin, they are marked with 4, and from thence are figured backwards, or towards the centre, to 12.

From the disposition of the double scales, it is plain, that those angles which were equal to each other, while the legs of the sector were close, will still continue to be equal, although the sector be opened to any distance it will admit of.

We shall now illustrate the nature of this instrument by examples.

Let CL, CL, (fig. 13) be the two lines of lines upon the sector, opened to an angle LCL; join the divisions 4 and 4, 7 and 7, 10 and 10, by the dotted lines *a, b, c d*, LL. Then by the nature of similar triangles, it is CL, to C *b*, as L L to *a b*; and C L to C *d*, as L L to *cd*; and therefore *a b* is the same part of L L as C *b* is of C L. Consequently, if L L be 10, then *a b* will be 4, and *c d* will be 7 of the same parts.

And hence, though the lateral scale C L be fixed, yet a parallel scale LL, is obtainable at pleasure; and therefore though the lateral radius is of a determined length in the lines of chords, sines, tangents and secants, yet the parallel radius may be had of any size you want, by means of the sector, as far as its length will admit; and all the parallel sines, &c. peculiar to it; as will be evident by the following examples in each pair of lines.

Ex. 1. *In the lines of equal parts.* Having 3 numbers given, 4, 7, 16, to find out a 4th proportional. To do this, take the lateral extent of 16 in the line C L, and apply it parallel-wise, from 4 to 4, by a proper opening of the sector; then take the parallel distance from 7 to 7 in your compasses, and applying one foot in C, the other will fall on 28 in the line of lines C L, and is the number required; for 4 : 7 : : 16 : 28.

Ex. 2. *In the lines of chords.* Suppose it required to lay off an angle A C B, (fig. 4) equal to 35 degrees; then with any convenient opening of the sector, take the extent from 60 to 60, and with it (as radius) on the point C describe the arch A D indefinitely; then in the same opening of the sector take the parallel distance from 35 degrees to 35 degrees, and set it from A to B in the arch A D and draw A B, and it makes the angle at C required.

Ex. 3. *In the lines of sines.* The lines of sines, tangents, and secants, are used in conjunction with the lines of lines in the solution of all the cases of plain trigonometry; thus let there be given in the triangle A B C, (fig. 14) the side A B = 230; and the angle A B C = 36° 30′; to find the side A C. Here the angle at C is 53° 30′. Then take the lateral distance 230, from the line of lines, and make it a parallel from 53° 30′ to 53° 30′ in the line of sines; then the parallel distance between 36° 30′ in the same lines, will reach laterally from the centre to 170, 19 in the line of lines for the side A C required.

Ex. 4. *In the lines of tangents.* If instead of making the side B C radius (as before) you make A B radius; then A C which before was a sine, is now the tangent of the angle B; and therefore to find it, you use the lines of tangents, thus:

Take the lateral distance 230 from the line of lines, and make it a parallel distance on the tangent radius, viz. from 45° to 45°, then the parallel tangent from 36° 30′, to 36° 30′, will measure laterally on the line of lines 170, 19, as before, for the side A C.

Ex. 5. *In the lines of secants.* In the same triangle, in the base A B, and the angles at B and C given, as before, to find the side or hypothenuse B C. Here B C is the secant of the angle B.

Take the lateral distance 230 from the line of lines, and make it a parallel distance on the tangent radius or beginnings of the lines of secants; then the parallel secant of 60° 30′ will measure laterally on the line of lines 287, 12, for the length of B C as required.

Ex. 6. *In the lines of sines and tangents conjointly.* In the solution of spherical triangles, you use the line of sines and tangents only, as in the following example. In the spherical triangle A B C (fig. 15) right-angled at A, there are given the side A B = 36° 15′, and the adjacent angle B = 42° 34′, to find the side A C. The analogy is radius: sine of A B : : tangent of B : tangent of AC;

therefore make the lateral sine of 36° 15′ a parallel at radius, or between 90 and 90; then the parallel tangent of 42° 34′ will give the lateral tangent of 28° 30′ for the side A C.

Ex. 7. *In the lines of polygons.* It has been observed that the chord of 60 degrees is equal to radius; and 60° is the sixth part of 360°; therefore such a chord is the side of a hexagon, inscribed in a circle: so that in the line of polygons, if you make the parallel distance between 6 and 6, the radius of a circle, as A C (fig. 16), then if you take the parallel distance between 5 and 5, and place it from A to B, the line A B will be the side of a pentagon A B D E F, inscribed in the circle; in the same manner may any other polygon, from 4 to 12 sides, be inscribed in a circle, or upon any given line A B.

Ex. 8. *Of Gunter's lines.* We have now shown the use of all that are properly called sectoral lines, or that are to be used sector-wise; but there is another set of lines usually put upon the sector, that will in a more ready and simple manner give the answers to the questions in the above examples, and these are called artificial lines of numbers, sines, and tangents: because they are only the logarithms of the natural numbers, sines, and tangents, laid upon lines of scales, which method was first invented by Mr. Edmund Gunter, and is the reason why they have ever since been called Gunter's lines, or the Gunter.

Logarithms are only the ratios of numbers, and the ratios of all proportional numbers are equal. Now all questions in multiplication, division, the rule of three, and the analogies of plain and spherical trigonometry, are all stated in proportional numbers or terms; therefore, if in the compasses you take the extent (or ratio) between the first and second terms, that will always be equal to the extent (or ratio) between the third and fourth terms; and consequently, if with the extent between the first and second terms, you place one foot of the compasses on the third term, then turning the compasses about, the other foot will fall on the fourth term sought.

Thus in example 1, of the three given numbers 4, 7, and 16, if you take the extent from 4 to 7 in the compasses, and place one foot in 16, the other will fall on 28 the answer, in the lines of numbers marked *n*.

Again, the artificial lines of numbers and sines, are used together in plain trigonometry, as in example 3, where the two angles B and C, and the side AB are given; for here if you take the extent of the two angles 53° 30′ and 36° 30′ in the line of sines marked *s*, then placing one foot upon 230 in the line of numbers *n*, the other will reach to 170, 19 the answer.

Also the lines of numbers and tangents are used conjointly, as in the example 4, for take in the line of tangents *t*, the extent from 45° (radius) to 36° 30′; that will reach from 230 to 170, 19 the answer as before.

Lastly, the artificial lines of sines and tangents are used together in the analogies of spherical triangles.

Thus example 6 is solved by taking in the line of sines *s*, the extent from 90° (radius) to 36° 15′, then that in the line of tangents *t*, will reach from 42° 34′ to 23° 30′, the answer required.

We shall only further observe that each pair of sectoral lines contain the same angle, viz. 6 degrees in the common 6-inch sector; therefore to open these lines to any given angle, as 35° for instance, you have only to take 35° laterally from the line of chords, and apply it parallelwise from 60° to 60° in the same lines, and they will all be opened to the given angle of 35°.

If to the angle 35° you add the angle 6°, which they contain, the sum is 41°: then take 41° laterally from the line of chords, and apply it parallelwise, from 60 to 60, then will the sides or edges of the sector contain the same angle of 35 degrees.

Of proportional compasses. Though this sort of compass does not pertain to a common case of instruments, yet a short account of their nature and use may not be unacceptable to those who are not acquainted with them. They consist of two parts or sides of brass, which lie upon each other, so nicely as to appear but one when they are shut. These sides easily open, and move about a centre, which is itself moveable in a hollow canal cut through the greatest part of their length. To this centre on each side is affixed a sliding piece of a small length, with a fine line drawn on it serving as an index, to be set against other lines or divisions placed upon the compasses on both sides. These lines are: 1. A line of lines. 2. A line of superficies, areas, or plans. 3. A line of solids. 4. A line of circles, or rather of polygons to be inscribed in circles.

These lines are all unequally divided, the three first from 1 to 10, the last from 6 to 20; their uses are as follow:

By the line of lines you divide a given line into any number of equal parts; for by placing the index against 1, and screwing it fast, if you open the compasses, then the distance between the points at each end will be equal. If you place the index against 2, and open the compasses, the distance between the points of the longer legs will be twice the distance between the shorter ones; and thus a line is bisected, or divided into two equal parts. If the index be placed against 3, and the compasses opened, the distances between the points will be as 3 to 1, and so a line is divided into three equal parts; and so you proceed for any other number of parts under 10.

The numbers of the line of plans answer to the squares of those in the line of lines; for because superficies or plans are to each other, as the square of their like sides; therefore if the index be placed against 2 in the line of plans, then the distance between the small points will be the side of a plan whose area is 1; but the distance of the larger points will be the like side of a plan whose area is 2, or twice as big. If the index be placed at 3, and the compasses opened, the distances between the points at each end will be the like sides of plans, whose areas are 1 to 3, and so of others.

The numbers of the line of solids answer to the cubes of those in the line of lines; because all solids are to each other as the cubes of their like sides or diameters; therefore, if the index be placed to No. 2, 3, 4, &c. in the line of solids, the distances between the lesser and larger points will be the like sides of solids, which are to each other as 1 to 2, 1 to 3, 1 to 4, &c. For example, if the index be placed at 10, and the compass be opened, so that the small points may take the diameter of a bullet weighing 1 ounce, then the distance between the larger points will be the diameter of a bullet or globe of 10 ounces, or which is 10 times as big.

Lastly the numbers in the line of circles are the sides of polygons to be inscribed in a given circle, or by which

a circle may be divided into those equal parts from 6 to 20. Thus if the index be placed at 6, the points of the compasses at either end, when opened to the radius of a given circle, will contain the side of a hexagon, or divide the circle into 6 equal parts. If the index be placed against 7, and the compasses opened, so that the larger points may take in the radius of the circle; then the shorter points will divide the circle into 7 equal parts for inscribing a heptagon. Again, placing the index to 8, and opening the compasses, the larger points will contain the radius, and the lesser points divide the circle into 8 equal parts, for inscribing an octagon or square. And thus you proceed for others.

Instruments, *surgical*. A case of pocket instruments for surgeons, which they ought always to carry about with them, contains lancets of different sizes; scissars fit for several uses; forceps, plain and furnished with teeth; incision-knives, straight and crooked; a spatula, probes, needles, &c. See Surgery.

INSURANCE, laws of. Insurance is regarded by the laws as a contract between two or more parties; that on one paying a certain premium he shall be indemnified or insured against certain risks set forth in the policy. This is extremely convenient in commerce, but was made use of as a kind of gambling till the statute 14 Geo. III. c. 48, that no insurance shall be made on lives, or on any other event, wherein the party insured hath no interest; that in all policies the name of such interested party shall be inserted, and nothing more shall be recovered thereon than the amount of the interest of the insured. This, however, does not extend to marine insurances. But as it was a common practice of insuring large sums without having property on board, and which were called wager policies or insurances, interest or no interest, and of ensuring the same goods several times over, it was enacted, that all insurances, interest or no interest, or without further proof of the interest than the policy, or by way of gaming, or without benefit of salvage to the insurer, should be void, except on privateers, or on ships or goods from the Spanish or Portuguese dominions; and that no re-assurance shall be legal, unless the former insurer be insolvent or dead; and that in the East India trade the lender of money on bottomry, or at respondentia, shall alone have a right to be insured for the money lent; and the borrower shall recover no more upon any insurance than the surplus of his bottomry or respondentia bond. No insurance can be made on any illegal voyage.

It is generally stipulated in policies that the insurer shall not be answerable for any partial loss on certain articles, but on others less difficult to be preserved at sea, but liable to partial injuries, shall be liable for any partial loss above five per cent.; and as to all other goods, and the ship and freight, he shall only be liable for such losses above three per cent. But he is liable on all losses, however small, called general average or losses occasioned by the ship stranding; but this loss must be an immediate, not a remote, consequence of the stranding.

The commencement of the risk on the ship varies in most cases, and usually continues till the ship has been 24 hours at safe anchor. Upon goods it commences when they are on board, and continues till they are removed or landed. The ship insured must be sound, and in every respect fit to bear the sea, and perform the voyage; and if she deviates from the usual course, and stops at places not usually stopped at, without a proper cause, the contract is void.

Insurance upon life is a contract by which the insurer, for a certain sum proportioned to the age, health, and profession of the person whose life is to be insured, engages that the person shall not die within a certain period, or if he do, the underwriter will pay a sum of money to the person to whom the policy is granted.

Insurance against fire. The insurer undertakes, in consideration of a premium, to indemnify the insured against all losses by fire which he may sustain in his house or goods during the time mentioned in the policy.

INTAGLIOS, precious stones on which are engraven the heads of great men, inscriptions, and the like; such as we frequently see set in rings, seals, &c.

INTEGER, in arithmetic, a whole number, in contradistinction to a fraction.

INTERCALARY, in chronology. See Bissextile, &c.

INTERCOMMONING, in law, is when the commons of two manors lie together, and the inhabitants of both have, time out of mind, caused their cattle to feed promiscuously on them.

INTERCOSTAL. See Anatomy.

INTERDICT, an ecclesiastical censure, by which the church of Rome forbids the performance of divine service in a kingdom, province, town, &c. This censure has been frequently executed in France, Italy, and Germany; and in the year 1170 pope Alexander III. put all England under an interdict, forbidding the clergy to perform any part of divine service, except baptising of infants, taking confessions, and giving absolution to dying penitents.

INTEREST, a sum of money, paid or allowed for the loan or use of some other sum, lent for a certain time, according to some fixed rate or proportion. The sum lent, and on which the interest is reckoned, is called the principal; and in any case where there is hazard of the loss or diminution of the principal, a proportionately greater interest is usually paid. The current rate of interest is generally considered as the barometer of public credit; and its lowness is a sign almost infallible of the flourishing condition of a state; it proves the increase of industry, and the free circulation of wealth, little inferior to a demonstration. In order to prevent individuals from taking unjust advantages of the necessities of others, it has been found necessary in most countries to establish by law a fixed rate of interest for the use of money: this however must, in a great measure, depend on the current rate of interest in the country; for if it is attempted to reduce by law the common rate of interest below the lowest ordinary market rate, the restriction will be sure to be evaded. This was the case in France in 1766, when, although the legal rate of interest was reduced from five to four per cent, money continued to be lent at five per cent.

The first act of parliament for regulating the interest for money lent in England was 37 Hen. VIII. c. 9. by which interest was fixed at 10 per cent.; before that time interest had usually been taken at higher rates. In 1552 an act was passed against usury, or taking any interest

whatever for money lent: the impolicy and oppression of this measure soon became evident; and in 1571 the statute of Henry VIII. which fixed interest at 10 per cent., was revived. As the increase of commerce brought wealth into the country, the rate of interest lowered; and in 1625 it was, by 21 James I. c. 17, reduced to eight per cent. The first positive law made in Scotland for fixing the rate of interest was in 1587, when an act was passed, by which the rate of interest was not for the future to exceed 10 per cent. In France, in 1601, Henry IV. issued an edict for reducing the public or national interest of money in that kingdom to six and a quarter per cent. In 1651 the interest of money in several parts beyond sea being lower than the legal interest in England, the Rump-parliament reduced the legal rate from eight to six per cent.; and upon the Restoration it was confirmed by 12 Cha. II. c. 13. The last act of parliament for regulating the interest of money was 12 Ann. st. 2. c. 16, by which it was fixed at five per cent. per annum, the present legal rate. But although this is the utmost interest which can be taken for money lent in Great Britain, yet if a contract which carries interest was made in a foreign country, our courts will direct the payment of interest according to the laws of the country in which the contract was made: thus American, Turkish, and Indian interest have been allowed, to the amount of even 12 per cent.

The various rates which have been paid in Great Britain at different periods, as the current interest for money, are as follows:

	Per cent. per ann.		
In 1255 - -	*L.*50	0	0
1263, 2*d.* a-week for 1*l.* or	43	6	8
1270 to 1307 -	45	0	0
1422 to 1470 -	15	0	0
1545 restricted to	10	0	0
1553 to 1558 -	12	0	0
1571 restricted to	10	0	0
1524 to 1604, about	9	16	0
1625 reduced to -	8	0	0
1645 to 1660 -	6	0	0
1660 to 1690 - -	7	6	6
1690 to 1697 - -	7	10	0
1697 to 1706 - -	6	0	0
1714 reduced to -	5	0	0

In the United States of America, the lawful interest of money is 6 per cent. in most of the states; in a few it is 7 per cent.; in one it is 5 per cent. In Greece, the mean rate of interest is 20 per cent, and in the other parts of Turkey nearly the same; in Persia 25 per cent.; and in the Mogul Empire 30 per cent. In these countries there is no fixed rate of interest, and the usual high rate arises chiefly from the insecurity of lending. In Sydney and the other English settlements in New South Wales, the rate of interest is fixed by an ordinance, dated 14th June, 1804, at 8 per cent. per annum.

Interest is disguished into *Simple Interest* and *Compound Interest.*

Interest, *Simple*, is that which is reckoned on the principal only, at a certain rate for a year. and at a proportionately greater or less sum for a greater or less time; thus, if 5*l.* is the rate of interest of 100*l.* for a year, 10*l.* is the interest for two years, 15l. for three years, &c. In most computations of interest the work is much shortened if the interest of 1*l.* for a given term is known, as the interest of any other sum for the same term will then be found by only multiplying by the given sum. The interest of 1*l.* for a year must be in the same proportion as the interest of 100*l.* to its principal; therefore at 5 per cent, as $100 : 5 :: 1 : \frac{5}{100} = ,05$; and thus:—

The interest of One Pound for One Year.

L.	*L.*
at 3 per cent. is -	,03
$3\frac{1}{2}$ - - -	,035
4 - - -	,04
$4\frac{1}{2}$ - - -	,045
5 - - -	,05
$5\frac{1}{2}$ - - -	,055
6 - - -	,06

The interest of One Pound for any number of years.

Years.	3 per Cent.	$3\frac{1}{2}$ per Cent.	4 per Cent.	$4\frac{1}{2}$ per Cent.	5 per Cent.
10	,3	,35	,4	,45	,5
20	,6	,7	,8	,9	1,0
30	,9	1,05	1,2	1,35	1,5
40	1,2	1,4	1,6	1,8	2,0
50	1,5	1,75	2,0	2,25	2,5
60	1,8	2,1	2,4	2,7	3,0
70	2,1	2,45	2,8	3,15	3,5
80	2,4	2,8	3,2	3,6	4,0
90	2,7	3,15	3,6	4,05	4,5
100	3,0	3,5	4,0	4,5	5,0

Although the law forbids any person lending money to take more than 5*l.* for the interest of 100*l.* for a year; yet by allowing the proportionate part of 5*l.* to be taken for part of a year, it permits any one who lends money for a less term than a year, to receive more than he ought if he were to make only five per cent. per annum of his money; for, if he lends 100*l.* for six months, he receives 102*l.* 10*s.*, and this being lent again for the remaining six months, amounts to 105*l* 1*s.* 3*d.*; if the time is less than six months the difference must be still greater. The letter of the law is however the rule in practice, and therefore the 365th part of the yearly interest is always considered as the proper interest for a day, and its multiples as the interest for any number of days.

As tables of Simple Interest are chiefly referred to, in order to find the interest or discount on bills of exchange, and as by far the greater number of bills which are discounted have less than 100 days to run, the following table will answer most useful purposes; but those who have constant occasion to make such computations,

will derive much assistance from the extensive tables which have been computed by Smart, Thomson, King, Reid, and others. See also DISCOUNT.

TABLE

Showing the Simple Interest of One Pound, for any number of days, not exceeding 100, at 5 per Cent.

days	Amount.	days	Amount.	days	Amount.
1	,0001369	35	,0047945	69	,0094520

21	,0028767	55	,0075342	89	.0121917
22	,0030137	56	,0076712	90	,0123287
23	,0031506	57	,0078082	91	.0124657
24	,0032876	58	,0079452	92	.0126027
25	,0034246	59	,0080821	93	.0127397
26	,0035616	60	,0082191	94	,0128767
27	,0036986	61	,0083561	95	,0130137
28	,0038356	62	,0084931	96	.0131506
29	,0039726	63	,0086301	97	.0132876
30	,0041095	64	,0087671	98	.0134246
31	,0042465	65	,0089041	99	.0135616
32	,0043835	66	,0090411	100	,0136986
33	,0045205	67	,0091780		
34	,0046575	68	,0093150		

The interest of any sum for any number of days contained in the table, is found by only multiplying the figures corresponding with the number of days by the sum: thus, if the interest of 150*l.* for 61 days is required, the interest of one pound for 61 days is, by the table, ,0083561, which multiplied by 150, gives 1*l.* 5*s.* 0$\frac{3}{4}$*d.* If the given sum contains shillings and pence, they must be reduced to the decimal of a pound. The interest for any greater number of days than are contained in the table, is easily found by means of it; thus, if it is required to find the interest of 100*l.* for 165 days, the interest for 100 days by the table is 1,36986, and for 65 days ,89041, which two sums added together, make 2,26027, or 2*l.* 5*s.* 2*d.* But, although it is most convenient in common practice to make use of tables for finding the interest for days, the interest of any sum for any number of days may be correctly and expeditiously obtained without the use of any table, by the following rule:

"Multiply the given sum by the number of days, and divide by 7300."

Example 1. What is the interest of 356*l.* for 112 days?

356 multiplied by 112, and divided by 7300, gives 5,4619, or 5*l.* 9*s.* 2$\frac{3}{4}$*d.*

Example 2. What is the interest of 137*l.* 18*s.* for 97 days?

137,9 multiplied by 97, and divided by 7300, gives 1,8323, or 1*l.* 16*s.* 7$\frac{3}{4}$*d.*

The amount of a given sum in any time may be found by multiplying the Principal, Time, and Rate together; and adding the product to the principal.

Example 1. What sum will 37*l.* 10*s.* amount to in 3 years and 146 days, at 4 per cent. per annum?

37,5 multiplied by 3,4, and the product multiplied by ,04, gives 5,1; which added to 37,5, makes 42,6, or 42*l.* 12*s.*

Example 2. What sum will One Penny amount to in 1816 years, at 5 per cent. per annum?

,004166 multiplied by 1816, and the product multiplied by ,05, gives ,3782728, which, added to the principal, makes ,3824388, or 7*s.* 7$\frac{3}{4}$*d.*

This example sets the difference between simple and compound interest in a most striking point of view; it appears that one penny put out at interest at the birth of Christ, would (at 5 per cent. simple interest) have amounted at the present time to 7*s.* 7$\frac{3}{4}$*d.*, but at compound interest, it would have increased in the same period to a greater sum than would be contained in six hundred millions of globes, each equal to the earth in magnitude, and all solid gold.

INTEREST, *compound*, is that which is reckoned on the principal and its interest put together, as the interest becomes due, so as to form a new capital from each period at which the interest is payable: it is sometimes called interest upon interest. It is not lawful to lend money at compound interest; but in the granting or purchasing of annuities, leases, or reversions, it is usual to allow the purchaser compound interest for his money; and the difference from simple interest is so great, in all cases in which the period of time is considerable, that almost all computations relating to annual payments of money for a number of years, are made at compound interest, unless it is otherwise agreed.

Let $r =$ the amount of 1*l.* in one year, viz. principal and interest.

$n =$ the number of years, in which

$p =$ the principal, increases to

$a =$ the amount:

then $1 : r :: r : r^2$ the amount of 1*l.* in 2 years

$1 : r :: r^2 : r^3$ the amount of 1*l.* in 3 years

$1 : r :: r^3 : r^4$ the amount of 1*l.* in 4 years.

&c.;

threfore r^n, or r raised to the power whose exponent is is the number of years, will be the amount of 1*l.* in those years; and as

1*l.* : $r^n :: p : a$, the amount of a given principal in the same time. Thus,

If Principal, Time, and Rate, are given, to find the Amount?

Theo. 1. $p \times r^n = a$.

If Amount, Time, and Rate, are given, to find the Principal?

Theo. 2. $\frac{a}{r^n} = p.$

If Principal, Amount, and Time, are given, to find the Rate?

Theo. 3. $\sqrt[n]{\frac{a}{p}} = r.$

If Principal, Amount, and Rate, are given, to find the Time?

Theo. 4. $\left\{\begin{array}{l}\frac{a}{p} = r^n, \text{ therefore } \frac{a}{p} \text{ being divided by } r \\ \text{till nothing remains, the number of di-} \\ \text{visions will } = n.\end{array}\right.$

But for greater convenience in practice, these theorems may be expressed in logarithms, as follows:

1. $\log. p + \overline{n \times \log. r} = \log. a.$
2. $\log. a - \overline{n \times \log. r} = \log. p.$
3. $\frac{\log. a - \log. p}{n} = \log. r.$
4. $\frac{\log. a - \log. p}{\log. r} = n.$

On these principles all tables of Compound Interest are formed, of which the following are the most useful.

TABLE I.

Showing the Sum to which 1l. Principal will increase at 5 per Cent. Compound Interest, in any number of years not exceeding a hundred.

Yrs.	Amount.	Yrs.	Amount.	Yrs.	Amount.
1	1.05	35	5.516015	69	28.977548

26	3.555672	60	18.678185	94	98 128263
27	3.733456	61	19.613145	95	03.034676
28	3.920129	62	20.593802	96	108.186410
29	4.116135	63	21.623492	97	113.595730
30	4.321942	64	22.704667	98	119.275517
31	4.538039	65	23.839900	99	125.239293
32	4.764941	66	25.031895	100	131.501257
33	5.003188	67	26.283490		
34	5.253347	68	27.597664		

In order to find what any sum will amount to in a given number of years, it is only necessary to multiply the number in the Table opposite to the term of years by the sum, and the product will be the answer.

Example. To what sum will 50*l.* increase in 69 years, at 5 per cent. compound interest?

The number in the table corresponding with 69 years is 28.977548, which multiplied by 50, gives 1448.8774, or 1448*l.* 17*s.* 6*d.*

The number of years in which a given sum will increase to another given sum in consequence of being improved at interest, is found by dividing the latter sum by the former, and the sum in the table which is nearest to the quotient will show the term required.

Example. In what time will 100*l.* increase to 500*l.*, if improved at 5 per cent?

Divide 500 by 100, and the number in the table nearest to 5 the quotient, is 5.003188, which shows that 33 years is the answer.

TABLE II.

Showing the present Value of 1l. to be received at the end of any number of years, not exceeding 100; discounting at 5 per Cent. Compound Interest.

Yrs.	Value.	Yrs.	Value.	Yrs.	Value.
1	.952381	35	.181290	69	.034509
2	.907029	36	.172657	70	.032866
3	.863838	37	.164436	71	.031301
4	.822702	38	.156605	72	.029811

32	.209866	66	.039949	100	.007604
33	.199873	67	.038047		
34	.190355	68	.036235		

In order to find the present worth of any sum which is to be received at the end of a certain number of years, multiply the number in the table opposite to the term of years, by the sum, and this product will be the answer.

Example. What is the present value of 500*l.* to be received at the expiration of 14 years?

The number in the table corresponding with 14 years, is .505068, which multiplied by 500, gives 252,534, or 252*l.* 10*s.* 8*d.*

For the present value or amount of annual payments, as Annuities, Pensions, Leases, &c. at Compound Interest, see ANNUITIES.

INTEREST, in law, is generally taken for a chattel real, or a lease for years, &c. but more for a future term.

An estate in lands, &c. is better than a bare interest therein; yet, according to the legal sense of the word, an interest extends to estates and titles which a person has in or out of lands, &c.; for by grant of a person's whole interest in land, a reversion, as well as possession, in fee-simple, passes.

INTERJECTION, in grammar, an indeclinable part of speech, signifying some passion or emotion of the mind.

INTERLOCUTORY ORDER, in law, an order that does not decide the cause, but only some matter incident to it, which happens between the beginning and end of a cause; as when, in chancery or exchequer, the plaintiff obtains an order for an injunction until the hearing of the cause; which order, not being final, is called interlocutory.

INTERMITTENT, or INTERMITTING FEVERS. See MEDICINE.

INTERNAL, in general, signifies whatever is within a thing.

Euclid proves that the sum of the three internal angles of every triangle is equal to two right angles; whence he deduces several useful corollaries. He likewise adduces, from the same proposition, this theorem, viz. that the sum of the angles of every rectilinear figure, is equal to twice as many right angles, as the figure hath sides, excepting or subtracting four.

INTERROGATORIES, are questions exhibited in writing to be asked witnesses or contemnors to be examined. Those interrogatories are in the nature of a charge or accusation; and if any of them is improper, the defendant may refuse to answer it, and move the court to have it struck out. Str. 444.

INTERSECTION, in the mathematics, signifies the cutting of one line or plane by another: thus we say, that the mutual intersection of two planes is a right line.

INTERVAL, in music, the difference in point of gravity or acuteness between any two sounds. Taking the word in its more general sense, we must allow that the possible intervals of sound are infinite, but we only speak of those intervals which exist between the different tones of any established system. The ancients divided the intervals into simple, or uncomposite, which they call diastems, and composite intervals, which they call systems. The least of all the intervals in the Greek music was, according to Bacchius, the enharmonic diesis, or fourth of a tone; but our scale does not notice so small a division, since all our tones concur in consonances, to which order only one of the three ancient genera, viz. the diatonic, was accommodated. Modern musicians consider the semitone as a simple interval, and only call those composite which consist of two or more semitones: thus from B to C is a semitone, or simple interval, but from C to D is two half-tones, or a compound interval.

INTESTATES. There are two kinds of intestates; one that makes no will at all; and another that makes a will, and nominates executors, but they refuse; in which case he dies an intestate, and the ordinary commits administration. 2 Par. Inst. 397.

The ordinary by special acts of parliament is required to grant administration of the effects of the deceased to the widow or next of kin, who shall first pay the debts of the deceased, and then distribute the surplus among the kindred, in the manner and according to the proportions directed by 22 and 23 Car. II. c. 10.

INTESTINA, in natural history, an order of vermes. The individuals of this order are of a formation the most simple, and live some of them within other animals, some in waters, and a few in the earth. The gordius perforates clay to give a passage to springs and water; the lumbricus pierces the earth, that it may be exposed to the action of the air and moisture: in like manner the teredo penetrates wood; and the phloas and mytillus rocks, to effect their dissolution.

INTESTINES. See ANATOMY, and PHYSIOLOGY.

INTRUSION, in law, is when the ancestor diesse ised of any estate of inheritance, expectant upon an estate for life; and then the tenant for life dies, between whose death, and the entry of the heir, a stranger intrudes.

INVECTED, in heraldry, denotes a thing fluted or furrowed. See HERALDRY.

INVENTION. See PAINTING.

INVESTITURE, in law, is the giving possession of lands by actual seisin. The ancient feudal investiture was, where the vassal on descent of land was admitted into the lord's court, and there received his seisin, in the nature of a renewal of his ancestor's grant, in the presence of the rest of the tenants: but in aftertimes, entering on any part of the lands, or other notorious possession, was admitted to be equivalent to the formal grant of seisin and investiture. 2 Black. 209.

The manner of grant was by words of pure donation, "have given and granted:" which are still the operative words in our modern infeodations or deeds of feoffment. This was perfected by the ceremony of corporal investiture, or open and notorious delivery of possession in the presence of the other vassals.

But a corporeal investiture being sometimes inconvenient, a symbolical delivery of possession was in many cases anciently allowed of; by transferring something near at hand, in the presence of credible witnesses, which by agreement should serve to represent the very thing designed to be conveyed; and an occupancy of this sign or symbol was permitted as equivalent to the occupancy of the land itself. And to this day, the conveyance of many of our copyhold estates is made from the seller to the lord, or his steward, by delivering a rod or verge, and then from the lord to the purchaser, by a re-delivery of the same, in the presence of a jury of tenants. 2 Black. 313.

INULA, fleabane, a genus of the syngenesia polygamia-superflua class of plants, with radiated flowers: the receptacle is naked; the down is simple; and the antheræ terminate in setæ at their bases. There are thirty-four species, of no note.

INVOICE, an account in writing of the particulars of merchandise, with their value, custom, charges, &c. transmitted by one merchant to another in a distant country.

One copy of every invoice is to be inserted verbatim in the invoice-book, for the merchant's private use; and another copy must, immediately upon shipping off the goods, be despatched by post, or otherwise, to the correspondent. This copy is commonly drawn out upon a sheet of large post-paper, to the end of which is subjoined a letter of advice.

INVOLUCRUM. See BOTANY.

INVOLUTION. See ALGEBRA.

IONIC ORDER. See ARCHITECTURE.

IPECACUANHA. See MATERIA MEDICA.

IPOMEA, *quamoclit*, or scarlet convolvulus, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 29th order, campanaceæ. The corolla is funnel-shaped; the stigma round-headed; the capsule trilocular. There are twenty-seven species; but not more than one (the coccinea) cultivated in our gardens. This has long, slender, twining stalks, rising upon support six or seven feet high, from the sides of which arise many slender footstalks, each supporting several large and beautiful funnel-shaped and scarlet flowers. There is a variety with orange-coloured flowers. Both of them are annual.

IRELAND. By statutes 39 and 40 Geo. III. c. 67. the kingdoms of Great Britain and Ireland shall, upon the first day of Jan. 1801, and for ever after, be united, by the name of the United Kingdom of Great Britain and Ireland; and the royal style and titles appertaining to the imperial crown of the said united kingdom and its dependancies, and also the ensigns armorial, flags and banners thereof, shall be such as his majesty, by his royal proclamation under the great seal of the united kingdom, shall be pleased to appoint.

Where a debt is contracted in England, and a bond is taken for it in Ireland, it shall carry Irish interest; for it must be considered as referable to the place where it is made: but if it was a simple-contract debt only, it ought to carry English interest, the variation of place in this case making no difference. 2 Atk. 382.

IRESINE, a genus of the pentandria order, in the diœcia class of plants; and in the natural method ranking under the 54th order, miscellaneæ. The male calyx is diphyllous, the corolla pentapetalous, and there are five nectaria. The female calyx is dyphyllous, the corolla pentapetalous; there are two sessile stigmata, and a capsule with flocky seeds. There is one species, a herb of Jamaica.

IRIDIUM, a new metal lately discovered by Mr. Tennant in the ore of platina. It is of a white colour, and perfectly infusible. It does not combine with sulphur or arsenic. Lead unites with it, but may be separated by cupellation. Copper, silver, and gold, are found to combine with it.

IRIS, the flower-de-luce, or flag-flower, &c.; a genus of the monogynia order in the triandria class of plants; and in the natural method ranking under the sixth order, ensatæ. The corolla is divided into six parts; the petals alternately reflexed; the stigmata resembling petals.

There are fifty species, all herbaceous flowering perennials, both of the fibrous, tuberous, and bulbous-rooted kind, producing thick annual stalks from three or four inches to a yard high, terminated by large hexapetalous flowers, having three of the petals reflexed quite back, and three erect; most of which are very ornamental, appearing in May, June, and July. All the species are easily propagated by offsets from the roots, which should be planted in September. October, or November, though almost any time from September to March will do. They may also be raised from seed, which is the best method for procuring varieties. It is to be sown in autumn, soon after it ripens, in a bed or border of common earth, and raked in. The plants will rise in the spring, and are to be transplanted next autumn.

IRON, the most abundant, and the most useful of all metals, was neither known so early, nor wrought so easily as gold, silver, and copper.

Iron is of a blueish white colour; and when polished, has a great deal of brilliancy. It has a styptic taste, and emits a smell when rubbed. Its specific gravity varies from 7.6 to 7.8. It is attracted by the magnet or loadstone, and is itself the substance which constitutes the loadstone. But when iron is perfectly pure, it retains the magnetic virtue a very short time. It is malleable in every temperature, and its malleability increases in proportion as the temperature augments; but it cannot be hammered out nearly so thin as gold or silver, or even copper. Its ductility, however, is more perfect; for it may be drawn out into wire as fine at least as human hair. Its tenacity is such, that an iron wire 0.078 of an inch in diameter is capable of supporting 549,25 lbs. avoirdupois without breaking. When heated to about 158° Wedgewood, it melts. This temperature being nearly the highest to which it can be raised, it has been impossible to ascertain the point at which this melted metal begins to boil and to evaporate. Neither has the form of its crystals been examined: but it is well known that the texture of iron is fibrous; that is, it appears when broken to be composed of a number of fibres or strings bundled together.

When exposed to the air, its surface is soon tarnished, and it is gradually changed into a brown or yellow powder, well known under the name of rust. This change takes place more rapidly if the atmosphere is moist. It is occasioned by the gradual combination of the iron with the oxygen of the atmosphere, for which it has a very strong affinity.

When iron filings are kept in water, provided the temperature is not under 70°, they are gradually converted in a black powder, while a quantity of hydrogen gas is emitted. This is occasioned by the slow decomposition of the water. The iron combines with its oxygen, while the hydrogen makes its escape under the form of gas.

If the steam of water is made to pass through a red-hot iron tube, it is decomposed instantly. The oxygen combines with the iron, and the hydrogen gas passes through the tube, and may be collected in proper vessels. This is one of the easiest methods of procuring pure hydrogen gas.

These facts are sufficient to show that iron has a strong affinity for oxygen, since it is capable of taking it from air and water. It is capable also of taking fire and burning with great rapidity. Twist a small iron wire into the form of a cork-screw, by rolling it round a cylin-

der; fix one end of it into a cork, and attach to the other a small bit of cotton thread dipt in melted tallow. Set fire to the cotton, and plunge it while burning into a jar filled with oxygen gas. The wire catches fire from the cotton, and burns with great brilliancy, emitting very vivid sparks in all directions. For this very splendid experiment we are indebted to Dr. Ingenhousz. During this combustion the iron combines with oxygen, and is converted into an oxide. Mr. Proust has proved that there are only two oxides of iron; and the protoxide has usually a black colour, but the peroxide is red.

The protoxide of iron may be obtained by four different processes. 1. By keeping iron filings a sufficient time in water at the temperature of 70°. The oxide thus formed is a black powder, formerly much used in medicine under the name of martial ethiops, and seems to have been first examined by Lemeri; but a better process is that of De Roover. He exposes a paste formed of iron filings and water to the open air, in a stone-ware vessel; the paste becomes hot, and the water disappears. It is then moistened again, and the process repeated till the whole is oxydized. The mass is then pounded, and the powder is heated in an iron vessel till it is perfectly dry, stirring it constantly. 2. By making steam pass through a red-hot iron tube, the iron is changed into a brilliant black brittle substance, which, when pounded, assumes the appearance of martial ethiops. This experiment was first made by Lavoisier. 3. By burning iron wire in oxygen gas. The wire as it burns is melted, and falls in drops to the bottom of the vessel, which ought to be covered with water, and to be of copper. These metallic drops are brittle, very hard, and blackish, but retain the metallic lustre. They were examined by Lavoisier, and found precisely the same with martial ethiops. They owe their lustre to the fusion which they underwent. By dissolving iron in sulphuric acid, and pouring potass into the solution. 4. A green powder falls to the bottom, which assumes the appearance of martial ethiops when dried quickly in close vessels. This first oxide of iron, however formed, is always composed of 73 parts of iron and 27 of oxygen, as Lavoisier and Proust have demonstrated. It is attracted by the magnet, and is often itself magnetic. It is capable of crystallizing, and is often found native in that state.

The peroxide or red oxide of iron may be formed by keeping iron filings red-hot in an open vessel, and agitating them constantly till they are converted into a dark red powder. This oxide was formerly called saffron of Mars. Common rust of iron is merely this oxide combined with carbonic acid gas. The red oxide may be obtained also by exposing for a long time a diluted solution of iron in sulphuric acid to the atmosphere, and then dropping into it an alkali, by which the oxide is precipitated. This oxide is also found native in great abundance. Proust proved it to be composed of 48 parts of oxygen and 52 of iron. Consequently the protoxide, when converted into red oxide, absorbs 0.40 of oxygen; or, which is the same thing, the red oxide is composed of 66.5 parts of black oxide and 33.5 parts of oxygen. One hundred parts of iron, when converted into a protoxide, absorb 37 parts of oxygen, and the oxide weighs 137; when converted into peroxide, it absorbs 52 additional parts of oxygen, and the oxide weighs 189.

The peroxide cannot be decomposed by heat; but when heated along with its own weight of iron filings, the whole, as Vauquelin first observed, is converted into black oxide. The reason of this conversion is evident: This 100 parts of peroxide are composed of 52 parts of iron, combined with two different doses of oxygen: 1. With 14 parts, which, with the iron, make 66 of protoxide: 2. With 34 parts, which, with the protoxide, make up the 100 parts of peroxide. Now, the first of these doses has a much greater affinity for the iron than the second has. Consequently the 34 parts of oxygen, which constitute the second dose, being retained by a weak affinity, are easily abstracted by the 100 parts of pure iron; and combining with the iron, the whole almost is converted into black oxide: for 100 parts of iron, to be converted into black oxide, require only 37 parts of oxygen.

The peroxide of iron is not magnetic. It is converted into black oxide by sulphureted hydrogen gas and many other substances; which deprive it of the second dose of oxygen, for which they have a stronger affinity, though they are incapable of decomposing the protoxide. Iron is capable of combining with all the simple combustible bodies.

A small mixture of it constitutes that particular kind of iron, known by the name of cold short iron, because it is brittle when cold, though it is malleable when hot.

Rinman has shown that the brittleness and bad qualities of cold short iron may be removed by heating it strongly with limestone, and with this the experiments of Levavasseur correspond.

There are a great many varieties of iron, which artists distinguish by particular names; but all of them may be reduced under one or other of the three following classes: cast iron; wrought or soft iron; and steel.

Cast iron, or pig iron, is the name of the metal when first extracted from its ores. The ores from which iron is usually obtained are composed of oxide of iron and clay. The object of the manufacturer is to reduce the oxide to the metallic state, and to separate all the clay with which it is combined. These two objects are accomplished at once, by mixing the ore reduced to small pieces with a certain portion of limestone and of charcoal, and subjecting the whole to a very violent heat in furnaces constructed for the purpose. The charcoal absorbs the oxygen of the oxide, flies off in the state of carbonic acid gas, and leaves the iron in the metallic state; the lime combines with the clay, and both together run into fusion, and form a kind of fluid glass; the iron is also melted by the violence of the heat, and being heavier than the glass, falls down, and is collected at the bottom of the furnace. Thus the contents of the furnace are separated into two portions; the glass swims at the surface, and the iron rests at the bottom. A hole at the lower part of the furnace is now opened, and the iron allowed to flow out into moulds prepared for its reception.

The cast iron thus obtained is distinguished by the following properties: It is scarcely malleable at any temperature. It is generally so hard as to resist the file. It can neither be hardened nor softened by ignition and cooling. It is exceeding brittle. It melts at 130° Wedgewood. It is more sonorous than steel. For the most part it is of a dark-grey or blackish colour; but sometimes it

is whitish, and then it contains a quantity of phosphuret of iron, which considerably impairs its qualities. A great number of utentials are formed of iron in this state.

To convert it into wrought iron, it is put into a furnace, and kept melted, by means of the flame of the combustibles, which is made to play upon its surface. While melted, it is constantly stirred by a workman, that every part of it may be exposed to the air. In about an hour the hottest part of the mass begins to heave and swell, and to emit a lambent blue flame. This continues nearly an hour; and by that time the conversion is completed. The heaving is evidently produced by the emission of an elastic fluid. As the process advances, the iron gradually acquires more consistency; and at last, notwithstanding the continuance of the heat, it congeals all together. It is then taken while hot, and hammered violently, by means of a heavy hammer driven by machinery. This not only makes the particles of iron approach nearer each other, but drives away several impurities which would otherwise continue attached to the iron.

In this state it is the substance described under the name of iron. As it has never yet been decomposed, it is considered at present, when pure, as a simple body; but it has seldom or never been found without some small mixture of foreign substances. These substances are either some of the other metals, or oxygen, carbon, or phosphorus.

When small pieces of iron are stratified in a close crucible, with a sufficient quantity of charcoal-powder, and kept in a strong red heat for eight or ten hours, they are converted into steel, which is distinguished from iron by the following properties.

It is so hard as to be unmalleable while cold, or at least it acquires this property by being immersed while ignited into a cold liquid: for this immersion, though it has no effect upon iron, adds greatly to the hardness of steel.

It is brittle, resists the file, cuts glass, affords sparks with flint, and retains the magnetic virtue for any length of time. It loses this hardness by being ignited and cooled very slowly. It melts at above 130° Wedgewood. It is malleable when red-hot, but scarcely so when raised to a white heat. It may be hammered out into much thinner plates than iron. It is more sonorous; and its specific gravity, when hammered, is greater than that of iron.

By being repeatedly ignited in an open vessel, and hammered, it becomes wrought iron, which is a simple substance, and if perfectly pure would contain nothing but iron.

Steel is iron combined with a small portion of carbon, and has been for that reason called carbureted iron. The proportion of carbon has not been ascertained with much precision. From the analysis of Vauquelin, it amounts, at an average, to $\frac{1}{140}$ part. Mr. Clouet seems to affirm that it amounts to $\frac{1}{32}$ part; but he has not published the experiments which led him to a proportion, which so far exceeds what has been obtained by other chemists.

That steel is composed of iron combined with pure carbon, and not with charcoal, has been demonstrated by Morveau, who formed steel by combining together directly iron and diamond. At the suggestion of Clouet, he inclosed a diamond in a small crucible of pure iron, and exposed it completely covered up in a common crucible to a sufficient heat.

The diamond disappeared, and the iron was converted into steel. The diamond weighed 907 parts, the iron 57800, and the steel obtained 56384; so that 2313 parts of the iron had been lost in the operation. From this experiment it follows, that steel contains about $\frac{1}{60}$ of its weight of carbon. This experiment was objected to by Mr. Mushet, but the objections were fully refuted by sir George M'Kenzie.

Rinman, long ago, pointed out a method by which steel may be distinguished from iron. When a little diluted nitric acid dropt upon a plate of steel, allowed to remain a few minutes, and then washed off, it leaves behind it a black spot; whereas the spot formed by nitric acid on iron is whitish-green. We can easily see the reason of the black spot: it is owing to the carbon of the iron which is converted into charcoal by the acid. This experiment shows us, that carbon is much more readily oxidated when combined with iron than when crystallized in the diamond.

Cast iron, is iron combined with a still greater proportion of carbon than is necessary for forming steel. The quantity has not yet been ascertained with precision: Mr. Clouet makes it amount to $\frac{1}{8}$ of the iron. The blackness of the colour, and the fusibility of cast iron, are proportional to the quantity of carbon which it contains. Cast iron is almost always contaminated with foreign ingredients: these are chiefly oxide of iron, phosphuret of iron, and silica.

It is easy to see why iron is obtained from its ore in the state of cast iron. The quantity of charcoal, along with which the ore is fused, is so great, that the iron has an opportunity of saturating itself with it.

The conversion of cast iron into wrought iron is effected by burning away the charcoal, and depriving the iron wholly of oxygen: this is accomplished by heating it violently while exposed to the air. Mr. Clouet has found, that when cast iron is mixed with $\frac{1}{4}$ of its weight of black oxide of iron, and heated violently, it is equally converted into pure iron. The oxygen of the oxide, and the carbon of the cast iron, combine, and leave the iron in a state of purity.

The conversion of iron into steel is effected by combining it with carbon. This combination is performed in the large way by three different processes, and the products are distinguished by the names of natural steel, steel of cementation, and cast steel.

Natural steel is obtained from the ore by converting it first into cast iron, and then exposing the cast iron to a violent heat in a furnace while its surface is covered with a mass of melted scoriæ five or six inches deep. Part of the carbon combines with the oxygen which cast iron always contains, and flies off in the state of carbonic acid gas. The remainder combines with the pure iron, and constitute it steel. This steel is inferior to the other species; its quality is not the same throughout; it is softer, and not so apt to break; and as the processes by which it is obtained are less expensive, it is sold at a lower price than the other species.

It is obvious that iron and carbon are capable of combining together in a variety of different proportions. When the carbon exceeds, the compound is carburet of

iron, or plumbago. When the iron exceeds, the compound is steel or cast iron in various states, according to the proportion. All these compounds may be considered as subcarburets of iron. The hardness of iron increases with the proportion of charcoal with which it combines, till the carbon amounts to about $\frac{1}{60}$ of the whole mass. The hardness is then a maximum; the metal acquires the colour of silver, loses its granulated appearance, and assumes a crystallized form. If more carbon is added to the compound, the hardness diminishes in proportion to its quantity.

The affinities of iron, and its oxides, are arranged by Bergman as in the following table:

Iron.	Oxide of Iron.
Nickel,	Oxalic acid,
Cobalt,	Tartaric,
Manganese,	Camphoric,
Arsenic,	Sulphuric,
Copper,	Saclatic,
Gold,	Muriatic,
Silver,	Nitric,
Tin,	Phosphoric,
Antimony,	Arsenic,
Platinum,	Fluoric,
Bismuth,	Succinic,
Lead,	Citric,
Mercury,	Lactic,
	Acetic,
	Boracic,
	Prussic,
	Carbonic.

Iron-sick, in the sea-language, is said of a ship or boat, when her bolts or nails are so eaten with rust, and so worn away, that they occasion hollows in the planks, whereby the vessel is rendered leaky.

IRRATIONAL, an appellation given to surd numbers and quantities. See Algebra.

IRREGULAR, in grammar, such inflections of words as vary from the general rules; thus we say, irregular nouns, irregular verbs.

ISATIS, woad; a genus of the siliquosa order, in the tetradynamia class of plants; and in the natural method ranking under the 39th order, the siliquosa. The siliqua is lanceolated, unilocular, monospermous, bivalved, and deciduous; the valves navicular or canoe-shaped. There are four species; but the only one worthy of notice in the tinctoria, or common woad, which is cultivated in several parts of Britain for the purposes of dyeing, being used as a foundation for many of the dark colours. See Dyeing.

ISCHÆMUM, a genus of the monœcia order, in the polygamia class of plants; and in the natural method ranking under the 4th order, gramina. The calyx of the hermaphrodite is a biflorous glume; the corolla bivalved; there are three stamina, two styles, and one seed. The calyx and corolla of the male, as in the former, with three stamina. There are eight species.

ISCHURY. See Medicine.

ISERTIA, a genus of the hexandria monogynia class and order; the cal. is coloured, four or six toothed; cor. six-cleft, funnel-form; pome subglobular, six-celled. There is one species, a tree of Cayenne.

ISINGLASS, in the materia medica, &c. See Accipenser.

ISNARDIA, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 17th order, calycanthemæ. There is no corolla; the calyx is quadrifid; the capsule quadrilocular, and girt with the calyx. There is one species, an aquatic and annual.

ISOCELES Triangle, in geometry, one that has two equal sides.

ISOCHRONAL, Isochrone, or Isochronous, is applied to such vibrations of a pendulum, as are performed in the same space of time; as all the vibrations or swings of the same pendulum are, whether the arches it describes are longer or shorter: for when it describes a shorter arch, it moves so much the slower, and when a long one proportionably faster.

Isochronal line, that in which a heavy body is supposed to descend without any acceleration.

ISOETES, a genus of the natural order of filices, belonging to the cryptogamia class of plants. The antheræ of the male flower are within the base of the frons or leaf. The capsule of the female flower is bilocular, and within the base of the leaf. There are two species.

ISOPERIMETRICAL Figures, in geometry, are such as have equal perimeters, or circumferences.

1. Of isoperimetrical figures, that is the greatest that contains the greatest number of sides, or the most angles, and consequently a circle is the greatest of all figures that have the same perimeter as it has.

2. Of two isoperimetrical triangles, having the same base, whereof two sides of one are equal, and of the other unequal, that is the greater whose two sides are equal.

3. Of isoperimetrical figures, whose sides are equal in number, that is the greatest which is equilateral and equiangular. From hence follows that common problem of making the hedging or walling that will wall in one acre, or even any determinate number of acres a, fence or wall in any greater number of acres whatever b. In order to the solution of this problem, let the greater number b be supposed a square. Let x be one side of an oblong, whose area is a; then will $\frac{a}{x}$ be the other side; and $2\frac{a}{x} + 2x$ will be the perimeter of the oblong, which must be equal to four times the square-root of b; that is, $2\frac{a}{2} + 2x = 4\sqrt{b}$. Whence the value of x may be easily had, and you may make infinite numbers of squares and oblongs that have the same perimeter, and yet shall have different given areas, thus

Let $\sqrt{b} = d$,

$$\text{Then, } \frac{2a + 4xx}{x} = 4d$$

$$a + 2xx = 2dx$$

$$2xx - 2dx = -a$$

$$xx - dx = -\frac{a}{2}$$

$$xx - dx + \tfrac{1}{4}dd = -\frac{a}{2} + \tfrac{1}{4}dd$$

$$x = \sqrt{-\frac{a}{2} + \tfrac{1}{4}dd} + \tfrac{1}{2}d.$$

Thus, if one side of the square be 10; and one side of an oblong be 19, and the other 1: then will the perimeters of that square and oblong be equal, viz. each 40, and yet the area of the square will be 100, and of the oblong but 19.

ISOPYRUM, in botany, a genus of the polygynia order, in the polyandria class of plants; and in the natural method ranking under the 26th order, multisiliquæ. There is no calyx, but five petals; the nectaria trifid and tubular; the capsules recurved and polyspermous. There are two species, of no note.

ISSUE, in law, has several significations, it being sometimes taken for the children begotten between a man and his wife; sometimes for profits arising from amercements and fines; and sometimes for the profits issuing out of lands or tenements: but this word generally signifies the conclusion, or point of matter, that issues from the allegations and pleas of the plaintiff and defendant in a cause to be tried by a jury or court.

There are two kinds of issues in relation to causes, that upon a matter of fact, and that upon a matter of law: that of fact is where the plaintiff and defendant have fixed upon a point to be tried by a jury: and that in law is where there are a demurrer to a declaration, &c. and a joinder in demurrer, which is determinable only by the judges. Issues of fact are either general or special: they are general, when it is left to the jury to find whether the defendant has done any such thing as the plaintiff has alleged against him; and special, where some special matter, or material point alleged by the defendant in his defence, is to be tried. General issue also signifies a plea in which the defendant is allowed to give the special matter in evidence, by way of excuse or justification; this is granted by several statutes, in order to prevent a prolixity in pleading, by allowing the defendant to give any thing in evidence, to prove that the plaintiff had no cause for his action.

Issues *on sheriffs*, are such amercements and fines to the crown, as are levied out of the issues and profits of the lands of sheriffs, for their faults and neglects: but these issues, on showing a good and sufficient cause, may be taken off before they are estreated into the exchequer.

Issues. See Surgery.

ITEA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The petals are long, and inserted into the calyx; the capsule unilocular and bivalved. There are two species, natives of North America.

IVA, a genus of the pentandria order, in the monœcia class of plants; and in the natural method ranking under the 49th order, compositæ. The male calyx is common and triphyllous; the florets of the disc monopetalous and quinquefid; the receptacle divided by small hairs. There is no female calyx nor corolla; but five florets in the radius; two long styles; and one naked and obtuse seed. There are two species, natives of America.

IVORY, ebur, in natural history, &c. a hard, solid, and firm substance, of a white colour, and capable of a very good polish. It is the tusk of the elephant, and is hollow from the base to a certain height, the cavity being filled up with a compact medullary substance, seeming to have a great number of glands in it. It is observed that the Ceylon ivory, and that of the island of Achem, do not become yellow in the wearing, as all other ivory does; for this reason the teeth of these places bear a larger price than those of the coast of Guinea.

To soften ivory and other bones, lay them for twelve hours in aqua fortis, and then three days in the juice of beets, and they will become so soft that they may be worked into any form. To harden them again, lay them in strong vinegar. Dioscorides says, that by boiling ivory for the space of six hours with the root of mandragoras, it will become so soft that it may be managed as one pleases.

Ivory-*black* is the coal of ivory or bone formed by great heat, while deprived of all access of air.

IVY. See Hedera.

IXIA, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the sixth order, ensatæ. The corolla is hexapetalous, patent, and equal; there are three stigmata, a little upright and petalous. There are fifty-four species, consisting of herbaceous, tuberous, and bulbous-rooted flowery perennials, from one to two feet high, terminated by hexapetalous flowers of different colours. They are propagated by offsets, which should be taken off in summer at the decay of the leaves: but as all the plants of this genus are natives of warm climates, few of them can bear the open air of this country in winter.

IXORA, a genus of the tetrandria monogynia class of plants. The corolla consists of a single petal; the tube is cylindric, very long and slender; the limb is plane, and divided into four oval segments; the fruit is a berry of a roundish figure, with only one cell; the seeds are four in number, convex on one side, and angular on the other. There are nine species, very ornamental shrubs for the stove.

J.

JACK, in mechanics, an instrument in common use for raising heavy timber, or very great weights of any kind, being a powerful combination of teeth and pinions, and the whole inclosed in a strong wooden stock or frame BC, and moved by a winch or handle HP; the outside appearing as in Plate LXXII. Miscel. fig. 131. In fig. 132, the wheel or rack work is shown, being the view of the inside when the stock is removed. Though it is not drawn in the just proportions and dimensions, for the rack AB must be supposed at least four times as long in proportion to the wheel Q, as the figure represents it; and the teeth, which will be then four times more in number, to have about three in the inch. Now if the handle HP is seven inches long, the circumference

of this radius will be 44 inches, which is the distance or space the power moves through in one revolution of the handle; but as the pinion of the handle has but four leaves, and the wheel Q suppose 20 teeth, or five times the number, therefore to make one revolution of the wheel Q, it requires five turns of the handle, in which case it passes through 5 times 44 or 220 inches; but the wheel having a pinion R of three leaves, these will raise the rack three teeth, or one inch, in the same space. Hence, then, the handle or power moving 220 times as fast as the weight, will raise or balance a weight of 220 times its own energy. And if this is the hand of a man who can sustain 50 pounds weight, he will, by the help of this jack, be able to raise or sustain a weight or force of 11000 pounds, or about five tons weight.

This machine is sometimes open behind from the bottom almost up to the wheel Q, to let the lower claw, which in that case is turned up as at B, draw up any weight. When the weight is drawn or pushed sufficiently high, it is kept from going back by hanging the end of the hook S, fixed to a staple, over the curved part of the handle at *h*.

The Society of Arts rewarded Mr. Mocock of Southwark, with a premium of 20 guineas, for his contrivance to prevent a jack from taking a retrogade course whenever the weight by any accidental circumstance overbalances the power. The improved jack only differs from those in common use in this respect, that it has a pall or clock, and ratchet, applied in such manner as to stop the motion of the machine as soon as it begins to run back again. As the difference in the mechanism is very trifling, the improvement may be easily applied to any common jacks already made.

Jack is also the name of a well-known engine in the kitchen, used for turning a spit. Here the weight is the power applied, acting by a set of pulleys; the friction of the parts, and the weight with which the spit is charged, are the forces to be overcome; and a steady uniform motion is maintained by means of a fly.

The common worm-jack is represented at Plate LXXII. Miscel. fig. 130. ABC is the barrel round which the cord QR is wound; KL the main wheel, commonly containing 60 teeth; N the worm-wheel of about thirty teeth, cut obliquely; LM the pinion, of about 15; O the worm or endless screw, consisting of two spiral threads, making an angle of sixty or seventy degrees with its axis; X the stud, and Z the loop of the worm-spindle; P a heavy wheel or fly, connected with the spindle of the endless screw to make the motion uniform; DG the struck wheel fixed to the axis FD; S,S,S, are holes in the frame, by which it may be nailed to a board, and thence to any wall, the end D being permitted to pass through it; HI the handle going upon the axis ET, to wind up the weight when it has run down. R is a box of fixed pulleys, and V a corresponding one of moveable pulleys carrying the weight. The axis ET is fixed in the barrel AC, which axis being hollow, both it and the barrel turn round upon the axis FD, which is fixed to the wheel KL, when it turns in the order BTA; but cannot turn the contrary way, by reason of a catch nailed to the end AB, which lays hold of the cross-bars in the wheel LK.

The weight by means of the cord QR, in consequence of its descent, carries about the barrel AB, which by the action of the catch carries the wheel KL, and this moves the pinion LM and wheel N, the latter moving the worm O and the fly P. Also the wheel LM carries the axis FD with the wheel DG, which carries the cord or chain that goes about the wheel or pulley at the head of the spit. But when the handle H gives motion to the axis in a contrary order to that given by the weight, the catch is depressed; so that although the barrel BC moves and winds the cord upon it, the wheel DG continues at rest. The time which the jack will continue in motion depends upon the number of pulleys at R and V: and as these increase or decrease, so must the weight which communicates the motion, in order to perform the same work in the same time.

Jack, *smoke*, is an engine used for the same purpose as the common jack; and is so called from its being moved by means of the smoke, or rarefied air, ascending the chimney, and striking against the sails of the horizontal wheel AB (Plate LXXII. Miscel. fig. 129), which being inclined to the horizon, is moved about the axis of the wheel, together with the pinion C, which carries the wheels D and E; and E carries the chain F, which turns the spit. The wheel AB should be placed in the narrow part of the chimney, where the motion of the smoke is swiftest, and where also the greatest part of it must strike upon the sails. The force of this machine depends upon the draught of the chimney, and the strength of the fire.

Smoke-jacks are sometimes moved by means of spiral flyers coiling about a vertical axle; and at other times by a vertical wheel with sails like the float-boards of a mill; but the above is the more customary construction.

JACK-flag, in a ship, that hoisted up at the sprit-sail top-mast head.

JACKALL. See Canis.

JACOB's staff, a mathematical instrument otherwise called cross-staff. See Cross.

JACOBITES, in church history, a sect of christians in Syria and Mesopotamia; so called either from Jacob, a Syrian, who lived in the reign of the emperor Mauricius; or from one Jacob, a monk, who flourished in the year 550.

JACOBUS, an ancient gold coin worth twenty-five shillings.

JACQUINIA, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is decemfid; the stamina inserted into the receptacle; the berry monospermous. There are four species, shrubs of South America.

JADE-stone, lapis nephriticus, or Jaspachates, a genus of siliceous earths. It gives fire with steel, and is semitransparent like flint. It does not harden in the fire, but melts in the focus of a burning-glass into a transparent green glass with some bubbles. A kind brought from the river of the Amazons in S. America, and called circoncision stone, melts more easily in the focus into a brown opaque glass, far less hard than the stone itself. The jade-stone is unctuous to the touch; whence Mr. Kirwan seems to suspect, that it contains a portion of argillaceous earth, or rather magnesia. The specific gravity is from 2.970 to 3.389; the texture granular,

with a greasy look, but exceedingly hard, being superior in this respect even to quartz itself. It is infusible in the fire, nor can it be dissolved in acids without a particular management; though M. Saussure seems to have extracted iron from it. Sometimes it is met with of a whitish milky colour from China; but mostly of a deep or pale green from America. The common lapis nephriticus is of a grey, yellowish, or olive colour. It has its name from a supposition of its being capable of giving ease in nephritic pains, by being applied externally by the loins. It may be distinguished from all other stones by its hardness, semipellucidity, and specific gravity.

According to Hoepfner it is composed of,

47	silica
38	carbonat of magnesia
9	iron
4	alumina
2	carbonat of lime
—	
100	

JALAP, *jalapa*, in botany, a plant of the pentandria monogynia class. See CONVOLVULUS, and MATERIA MEDICA.

JAMES, or *knights of St. James*, a military order in Spain, first instituted about the year 1170, by Ferdinand II. king of Leon and Galicia.

JANIZARIES, an order of the Turkish infantry, reputed the grand signior's guards, and the main strength of the Ottoman army.

JANSENISTS, in church-history, a sect of the Roman catholics in France, who follow the opinions of Jansenius, bishop of Ypres, and doctor of divinity of the universities of Louvain and Douay, nearly those of Calvin in relation to grace and predestination.

JAPANNING is properly the art of varnishing and painting ornaments on wood, in the same manner as is done by the natives of Japan in the East Indies.

The substances which admit of being japanned are almost every kind that are dry and rigid, or not too flexible; as wood, metals, leather, and paper, prepared for the purpose.

Wood and metals do not require any other preparation, but to have their surface perfectly even and clean; but leather should be securely strained, either on frames or on boards; as its bending, or forming folds, would otherwise crack and force off the coats of varnish. Paper should be treated in the same manner, and have a previous strong coat of some kind of size; but it is rarely made the subject of japanning till it is converted into papier mache, or wrought by other means into such form, that its original state, particularly with respect to flexibility, is changed.

One principal variation from the method formerly used in japanning is, the omitting any priming, or undercoat; on the work to be japanned. In the other practice, such a priming was always used; the use of which was to save in the quantity of varnish, by filling up the inequalities in the surface of the substance to be varnished. But there is a great inconvenience arising from the use of it, that the Japan coats are constantly liable to be cracked, and peeled off, by any violence, and will not endure near so long as the articles which are japanned without any such priming.

Of the nature of Japan grounds.—When a priming is used, the work should first be prepared by being well smoothed with fish-skin or glass-paper, and being made throughly clean, should be brushed over once or twice with hot size, diluted with two thirds water, if it is of the common strength. The priming should then be laid on as even as possible, and should be formed of a size, of a consistency between the common kind and glue, mixed with as much whiting as will give it a sufficient body of colour to hide the surface of whatever it is laid upon, but not more. This must be repeated till the inequalities are completely filled up, and then the work must be cleaned off with Dutch rushes, and polished with a wet rag.

When wood or leather is to be japanned, and no priming is used, the best preparation is to lay two or three coats of coarse varnish, composed in the following manner.

Take of rectified spirit of wine one pint, and of coarse seed-lac and resin each two ounces; dissolve the seed-lac and resin in the spirit, and then strain off the varnish.

This varnish, as well as all others formed of spirit of wine, must be laid on in a warm place; and if it can be conveniently managed, the piece of work to be varnished should be made warm likewise; and for the same reason, all dampness should be avoided; for either cold or moisture chills this kind of varnish, and prevents its taking proper hold of the substance on which it is laid.

When the work is so prepared, or by the priming with the composition of size and whiting above described, the proper japan ground must be laid on, which is much the best formed of shell-lac varnish, and the colour desired, except white, which requires a peculiar treatment; and if brightness is wanted, then also other means must be pursued.

The colours used with the shell-lac varnish may be any pigments whatever, which give the tint of the ground desired.

As metals never require to be under-coated with whiting, they may be treated in the same manner as wood or leather.

Method of painting Japan work.—Japan work ought properly to be painted with colours in varnish; though, for the greater dispatch, and in some very nice work in small, for the freer use of the pencil, the colours are sometimes tempered in oil; which should previously have a fourth part of its weight of gum animi dissolved in it; or in default of that gum sandarach, or gum mastich. When the oil is thus used, it should be well diluted with oil of turpentine, that the colours may lie more evenly and thin; by which means fewer of the polishing or upper coats of varnish become necessary.

In some instances, water-colours are laid on grounds of gold, in the manner of other paintings; and are best, when so used in their proper appearance, without any varnish over them; and they are also sometimes so managed as to have the effect of embossed work. The colours employed in this way, for painting, are best prepared by means of isinglass size, corrected by honey or sugar-candy. The body, of which the embossed work is raised, need not, however, be tinged with the exterior colour, but may be best formed of very strong gum-water, thickened to a proper consistence by bole armenian and

whiting in equal parts; which being laid on the proper figure, and repaired when dry, may be then painted with the proper colours, tempered with the isinglass size, or, in the usual manner, with shell-lac varnish.

Manner of varnishing japan work.—The finishing of japan-work depends on the laying on, and polishing, the outer coats of varnish which are necessary, as well in the pieces that have only one simple ground of colour, as with those that are painted. This is in general done best with common seed-lac varnish, except in the instances, and on those occasions, where particular methods are deemed to be more expedient; and the same reasons which decide as to the fitness or impropriety of the varnishes, with respect to the colours of the ground, hold equally with regard to those of the painting. For where brightness is the most material point, and a tinge of yellow will injure it, seed-lac must give way to the whiter gums; but where hardness and a greater tenacity are most essential, it must be adhered to; and where both are so necessary, that it is proper one should give way to the other in a certain degree reciprocally, a mixed varnish must be adopted.

This mixed varnish, as we have already observed, should be made of the picked seed-lac. The common seed-lac varnish, which is the most useful preparation of the kind hitherto invented, may be thus made.

Take of seed-lac three ounces, and put it into water, to free it from the sticks and filth that are frequently intermixed with it; and which must be done by stirring it about, and then pouring off the water, and adding fresh quantities, in order to repeat the operation, till it is freed from all impurities, as is very effectually done by this means. Dry it then, and powder it grossly, and put it, with a pint of rectified spirit of wine, into a bottle, of which it will not fill above two-thirds. Shake the mixture well together, and place the bottle in a gentle heat, till the seed-lac appears to be dissolved; the shaking being in the mean time repeated as often as may be convenient; and then pour off all that can be obtained clear by this method, and strain the remainder through a coarse cloth. The varnish thus prepared, must be kept for use in a bottle well stopped.

When the spirit of wine is very strong, it will dissolve a greater proportion of the seed-lac; but this quantity will saturate the common, which is seldom of a strength sufficient to make varnishes in perfection. As the chilling, which is the most inconvenient accident attending varnishes of this kind, is prevented or produced more frequently, according to the strength of the spirit; we shall therefore take this opportunity of showing a method by which weaker rectified spirits may with great ease at any time be freed from the phlegm, and rendered of the first degree of strength.

Take a pint of the common rectified spirit of wine, and put it into a bottle, of which it will not fill above three parts; add to it half an ounce of pearl-ashes, salt of tartar, or any other alkaline salt, heated red-hot, and powdered as well as it can be without much loss of its heat. Shake the mixture frequently for the space of half an hour; before which time, a great part of the phlegm will be separated from the spirit, and will appear, together with the undissolved part of the salts, in the bottom of the bottle. Let the spirit be poured off, or freed from the phlegm and the salts, by means of a tritorium, or separating funnel; and let half an ounce of the pearl-ashes, heated and powdered as before, be added to it, and the same treatment repeated. This may be done a third time, if the quantity of phlegm separated by the addition of the pearl-ashes appears considerable. An ounce of alum reduced to powder, and made hot, but not burnt, must then be put into the spirit, and suffered to remain some hours, the bottle being frequently shaken: after which the spirit, being poured off from it, will be fit for use.

The addition of the alum is necessary to neutralize the remains of the alkaline salt, which would otherwise greatly deprave the spirit, with respect to varnishes and lacquer where vegetable colours are concerned, and must consequently render another distillation necessary.

The manner of using the seed-lac, or white varnish, is the same, except with regard to the substance used in polishing: which, where a pure white of a great clearness of other colours is in question, should be itself white; whereas the browner sorts of polishing-dust, as being cheaper, and doing their business with greater despatch, may be used in other cases. The pieces of work to be varnished, should be placed near a fire, or in a room where there is a stove, and made perfectly dry; and then the varnish may be rubbed over them by the proper brushes made for that purpose, beginning in the middle, and passing the brush to one end, and then with another stroke from the middle, passing it to the other. But no part should be crossed, or twice passed over, in forming one coat, where it can be possibly avoided. When one coat is dry, another must be laid over it; and this must be continued at least five or six times, or more, if on trial, there is not sufficient thickness of varnish to bear the polish, without laying bare the painting or ground-colour underneath.

When a sufficient number of coats is thus laid on, the work is fit to be polished; which must be done, in common cases, by rubbing it with a rag dipped in tripoli, or rottenstone, finely powdered; but, towards the end of the rubbing, a little oil of any kind should be used along with the powder; and when the work appears sufficiently bright and glossy, it should be well rubbed with the oil alone, to clean it from the powder, and give it a still brighter lustre.

JARGON. See Zircon.

JASIONE, a genus of the monogamia order, in the sygenesia class of plants, and in the natural method ranking under the 49th order, campanaceæ. The common calyx is ten-leaved; and the corolla has five regular petals; the capsule beneath, two-celled. There are four species, shrubs of the West Indies.

JASMINUM, Jasmine, or Jessamine tree, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking under the 44th order, sepiariæ. The corolla is salver-shaped, the berry dicoccous; the seeds arillated, the antheræ within the tube. There are 17 species. The most remarkable are: 1. The officinalis, or common white jasmine, with shrubby long slender stalks and branches, rising upon supports 15 or 20 feet high, with numerous white flowers from the joints and ends, of a very fragrant odour. There is a variety with white-striped, and another with yellow-striped

sail extended from the outer end of the bowsprit prolonged by the jib-boom, towards the fore-top-mast head. See SAIL.

JIB-*boom*, a boom run out from the extremity of the bowsprit, parallel to its length, and serving to extend the bottom of the jib, and the stay of the fore-top-gallant-mast.

JOINT ACTIONS: in personal actions, several wrongs may be joined in one writ; but actions founded upon a tort and a contract cannot be joined, for they require different pleas and different process. 1 Vent. 336.

JOINT AND SEVERAL: an interest cannot be granted jointly and severally; as if a man grants the next advowson, or makes a lease for years, to two jointly and severally; these words (severally) are void, and they are joint tenants. 5 Rep. 19.

JOINT LIVES: lease for years to husband and wife, if they or any issue of their bodies should so long live, has been adjudged so long as either the husband, wife, or any of their issue, should live; and not only so long as the husband and wife, &c. should jointly live. Moor, 539.

JOINT TENANTS, are those that come to, and hold lands or tenements by one title pro indiviso, or without partition.

These are distinguished from sole or several tenants, from parceners, or from tenants in common: and they must jointly implead, and jointly be impleaded by others, which properly is common between them and coparceners; but joint tenants have a sole quality of survivorship, which coparceners have not; for if there are two or three joint tenants, and one has issue and dies, then he or those joint tenants that survive, shall have the whole by survivorship. Cowel.

The creation of an estate in joint tenantcy depends on the wording of the deed or device, by which the tenant claims title; for this estate can only arise by purchase or grant, that is, by the act of the parties; and never by the mere act of law. Now if any estate is given to a plurality of persons, without adding any restrictive, exclusive, or explanatory words, as if an estate is granted to A and B and their heirs, this makes them immediately joint tenants in fee of the lands; for the law interprets the grant, so as to make all parts of it take effect, which can only be done by creating an equal estate in them both. As therefore the grantor has thus united their names, the law gives them a thorough union in all other respects. 2 Black. 180.

If there are two joint tenants, and one releases the other, this passes a fee without the word heirs; because it refers to the whole fee, which they jointly took, and are possessed of by force of the first conveyance; but the tenants in common cannot release to each other, for a release supposes the party to have the thing in demand, but tenants in common have several distinct freeholds, which they cannot transfer otherwise than as persons who are sole seized. Co. Lit. 9.

Although joint tenants are seized per mie et per tout, yet to divers purposes each of them has but a right to a moiety; as to enfeoff, give, or demise, or to forfeit or lose by default in a præcipe; and therefore where there are two or more joint tenants, and they all join in a feoffment, or each of them in judgment gives but his part. Co. Lit. 186.

The right of survivorship shall take place immediately upon the death of the joint tenant, whether it is a natural or civil death; as if there was no joint tenants, and one of them enters into religion, the survivor shall have the whole. Co. Lit. 181.

At common law, joint tenants in common were not compellable to make partition, except by the custom of some cities and boroughs. Co. Lit. 187.

But now joint tenants may make partition; the one party may compel the other to make partition, which must be by deed: that is to say, all the parties must by deed actually convey and assure to each other the several estates, which they are to take and enjoy severally and separately. 2 Black. 324.

Joint tenants being seized per mie et per tout, and deriving by one and the same title, must jointly implead, and be jointly impleaded with others. Co. Lit. 180.

If one joint tenant refuses to join in action, he may be summoned and severed; but herein it is to be observed, that if the person severed dies, the writ abates, because the survivor then goes for the whole, which he cannot do on that writ, where on the summons and severance he went only for a moiety before; for the writ cannot have a double effect, to wit, for a moiety in case of summons and severance, and for the whole in case of survivorship. Co. Lit. 188.

But in personal and mixed actions where there is summons and severance, and yet after such summons and severance the plaintiff goes on for the whole, there if one of them dies, yet the writ shall not abate, because they go on for the whole after summons and severance; and if they were to have a new writ, it would only give the court authority to go on for the whole. Co. Lit. 197.

JOINTURE. A jointure strictly speaking; signifies a joint estate, limited to both husband and wife; but in common acceptation, it extends also to a sole estate, limited to the wife only, and may be thus defined, viz. a competent livelihood of freehold for the wife of lands and tenements, to take effect, in profit or possession, presently after the death of the husband; for the life of the wife at least. 2 Black. 137.

By the statute of the 27th H. VIII. c. 10, if a jointure is made to the wife, it is a bar of her dower, so that she shall not have both jointure and dower. And to the making of a perfect jointure within that statute six things are observed: 1. Her jointure is to take effect presently after her husband's decease. 2. It must be for the term of her own life, or greater estate. 3. It should be made to herself. 4. It must be made in satisfaction of her whole dower, and not of part of her dower. 5. It must either be expressed or averred to be in satisfaction of her dower. 6. It should be made during the coverture. 1 Inst. 32.

The estate must take effect presently after her husband's disease; therefore if an estate is made to the husband for life, remainder to another person for life, remainder to the wife for her jointure, this is no good jointure, for it is not within the words or intent of the statute; for the statute designed nothing as a satisfaction for dower, but that which came in the same place, and is of the same use to the wife; and though the other person dies during the life of the husband, yet this is not good; for every interest not equivalent to dower not being

within the statute, is a void limitation to deprive the wife of her dower. 4 Co. 3.

The estate must be for the term of the wife's life, or a greater estate; therefore if an estate is made for the life or lives of many others, this is no good jointure; for if she survives such lives, as she may, then it would be no competent provision during her life, as every jointure within the statute ought to be. Co. Lit. 36.

The estate should be made to herself; but as the intention of the statute was to secure the wife a competent provision, and also to exclude her from claiming dower, and likewise her settlement, it seems that a provision or settlement on the wife, though by way of trust, if in other respects it answers the intention of the statute, will be inforced in a court of equity.

The estate must be in satisfaction of the whole dower; the reason hereof is, that if it is made in satisfaction of part only, it is uncertain for what part it is in satisfaction of her dower, and therefore void in the whole. Co. Lit. 36.

The estate must be expressed or averred to be in satisfaction of her dower. Lord Coke says, that it must be expressed or averred to be in satisfaction of her dower; but quære, for this does not seem requisite either within the words or intention of the statute. Co. Lit. 36.

It should be made during the coverture; this the very words of the act of parliament require: and therefore if a jointure is made to a woman during her coverture in satisfaction of dower, she may wave it after her husband's death; but if she enters and agrees thereto, she is concluded; for though a woman is not bound by any act when she is not at her own disposal, yet if she agrees to it when she is at liberty, it is her own act, and she cannot avoid it. Co. Lit. 36. 4 Co. 3.

JOISTS, or Joysts. See Architecture.

JONCQUETIA, a genus of the decandria tetragynia class and order. The cal. is five-leaved; pet. five and spreading; filaments growing to a glandule; styles none; caps. sub-globular, one-celled, five-valved, five-seeded. There is one species, a large tree of Guiana.

JONK, or Jonque, in naval affairs, is a kind of small ship, very common in the East Indies: these vessels are about the bigness of our fly-boats, and differ in the form of their building, according to the different methods of naval architecture used by the nations to which they belong. Their sails are frequently made of mats, and their anchors are made of wood.

JOURNAL, at sea. See Navigation.

JUDGE. The judges are the chief magistrates in the law, to try civil and criminal causes. Of these there are twelve in England, viz. the lords chief justices of the courts of king's-bench and common-pleas; the lord chief baron of the exchequer; the three puisne or inferior judges of the two former courts, and the three puisne barons of the latter.

By stat. 1 Geo. III. c. 23. the judges are to continue in their offices during their good behaviour, notwithstanding any demise of the crown (which was formerly held immediately to vacate their seats), and their full salaries are absolutely secured to them during the continuance of their commissions, by which means the judges are rendered completely independant of the king, his ministers, or his successors.

A judge at his creation takes an oath, that he will serve the king, and indifferently administer justice to all men, without respect of persons, take no bribe, give no counsel where he is a party, nor deny right to any, though the king or any other, by letters, or by expressed words, command the contrary, &c. and in default of duty, to be answerable to the king in body, land, and goods.

Where a judge has an interest, neither he nor his deputy can determine a cause, or sit in court; and if he does, a prohibition lies. Hardw. 503.

Judges are punishable for wilful offences, against the duty of their situations; instances of which happily live only in remembrance. There are ancient precedents of judges who were fined when they transgressed the laws, though commanded by warrants from the king.

Judge is not answerable to the king, or the party, for mistakes or errors of his judgment, in a matter of which he has jurisdiction. 1 Salk. 397.

JUDGMENT. The opinion of the judges is so called, and is the very voice and final doom of the law, and therefore is always taken for unquestionable truth; or it is the sentence of the law pronounced by the court, upon the matter contained in the record.

Judgments are of four sorts, viz. 1. Where the facts are confessed by the parties, and the law determined by the court, which is termed judgment by demurrer.

2. Where the law is admitted by the parties, and the facts only are disputed, as in judgment upon a demurrer.

3. Where both the fact and the law arising thereon are admitted by the defendant, as in case of judgment by confession or default.

4. Where the plaintiff is convinced that fact or law, or both, are insufficient to support his action, and therefore abandons or withdraws his prosecution, as in case of judgment upon a nonsuit or retraxit. See Warrant of Attorney.

Judgments are either interlocutory or final.

Interlocutory judgments are such as are given in the middle of a cause, upon some plea, proceeding, or default, which is only intermediate, and does not finally determine or complete the suit; as upon dilatory pleas, when the judgment in many cases is, that the defendant shall answer over; that is, put in a more substantial plea.

Final judgments, are such as at once put an end to the action, by declaring that the plaintiff has either entitled himself, or has not, to recover the remedy he sues for. 3 Black. 398.

JUGERUM, in Roman antiquity, a square of 120 Roman feet; its proportion to the English acre being as 10,000 to 16,097.

JUGLANS, the walnut, a genus of the monœcia class, and polyandria order of plants; and in the natural method ranking under the 50th order, amentaceæ. The male calyx is monophyllous, and squamiform; the corolla divided into six parts; there are 18 filaments: the female calyx is quadrifid, superior; the corolla quadripartite; there are two styles, and the fruit is a plum with a furrowed kernel. There are 8 species, the most remarkable of which is the regia or common walnut. Other two species, called the nigra and alba, or black and white Virginian walnut, are also cultivated in this country, though they are less proper for fruit, having very small kernels.

fits of his land during life, and suffer perpetual imprisonment.

Jury-mast, whatever is set up in room of a mast that has been lost in a storm or in an engagement, and to which a lesser yard, ropes, and sails, are fixed.

JUSSIÆA, a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 17th order, calycanthemæ. The calyx is quadripartite, or quinquepartite superior; there are four or five petals; the capsule quadrilocular or quinquelocular, oblong, opening at the angles: the seeds are numerous and small. There are 11 species, mostly herbaceous plants of the W. Indies.

JUSTICE, in a legal sense, a person deputed by the king to administer justice to his subjects, whose authority arises from his deputation, and not by right of magistracy.

In the courts of king's bench and common pleas there are two judges styled chief justices, each of whom retains the title of lord during the time of his continuing in office. The first of these, who is styled lord chief justice of England, has a very extensive power and jurisdiction in pleas of the crown. He hears all pleas in civil causes brought before him in the court of king's bench, and also the pleas of the crown; while, on the other hand, the lord chief justice of the common pleas has the hearing of all civil causes between common persons. Besides the lords chief justices, there are in each of the above courts three puisne justices; there are also several other justices appointed by the king for the execution of the laws; such as the lords justices in eyre of the forests, who are two justices appointed to determine all offences committed in the king's forests; justices of assize, of oyer and terminer, of gaol-delivery, &c. They are also called justices of nisi prius, and so denominated from the words usual in a common form of adjournment of a cause in the court of common pleas. See Nisi Prius, Oyer and Terminer, Common Pleas, and King's Bench.

Justices *of the Peace*. See Peace.

JUSTICIARY, or court of Justiciary, in Scotland, a court of supreme jurisdiction in all criminal cases.

This court came in place of the justice-eyre or justice-general, which last was taken away by parliament in 1672, and was erected into a justice or criminal court, consisting of a justice-general alterable at the monarch's pleasure, justice clerk, and five other judges, who are lords of session.

This court commonly sits upon Mondays, and has an ordinary clerk, who has his commission from the justice-clerk. They have four macers, and a doomster appointed by the lords of the session.

The form of the process is this: the clerk raises a libel or indictment upon a bill passed by any of the lords of that court, at the instance of the pursuer, against the defendant or criminal, who is immediately committed to prison after citation. When the party, witnesses, great assize, or jury of forty-five men, are cited, the day of compearance being come, fifteen of the great assize are chosen to be the assize upon the pannel, or prisoner at the bar. The assize sits with the judges to hear the libel read, witnesses examined, and the debates on both sides, which are written verbatim in the adjournal books. The king's advocate pleads for the pursuer, being the king's cause, and other advocates for the pannel. The debates being closed, the judges find the libel or indictment either non-relevant, in which case they desert the diet, and assoil or absolve the party accused; or, if relevant, then the assize or jury of fifteen is removed into a closer room, none being present with them, where they choose their chancellor and clerk, and consider the libel, deposition, and debates; and bring in their verdict of the pannel sealed, guilty or not guilty: if not guilty, the lords absolve; if guilty, they condemn and declare their sentence of condemnation, and command the sentence to be pronounced against the pannel by a macer and the mouth of the doomster. The lords of the justiciary likewise go circuits twice a year into the country. See the article Circuit.

JUSTICIES, a writ directed to a sheriff, by virtue of which he is empowered to hold a plea of debt in his county-court for a sum above 40*s.* though by his ordinary power he has only cognizance of sums under 40*s.*

JUSTIFICATION, in law, is an affirming or showing good reason in court, why one does such a thing as he is called to answer; as to justify in a cause of a replevin.

JUSTICIA, Malabar nut; a genus of the monogynia order, in the diandria class of plants; and in the natural method ranking under the 40th order, personatæ. The corolla is ringent; the capsule bilocular, parting with an elastic spring at the heel; the stamina have only one anthera. There are eighty species, most of them natives of the East Indies, growing many feet high; some adorned with fine large leaves, others with small narrow ones, and all of them with monopetalous ringent flowers. Only two species are commonly cultivated in our gardens, viz. the adhatoda, or common Malabar nut, and the hyssopifolia or snap-tree. The first grows ten to twelve feet high, with a strong woody stem; and from the ends of the branches short spikes of white flowers, with dark spots, having the helmet of the corolla concave. The second has a shrubby stem, and white flowers, commonly by threes, from the sides of the branches; succeeded by capsules, which burst open with elastic force for the discharge of the seeds; whence the name of snap-tree.

JYNX, the wryneck, a genus of birds belonging to the order of picæ; the characters of which are, that the bill is slender, round, and pointed; the nostrils are concave and naked; the tongue is very long, very slender, cylindric, and terminated by a hard point; and the feet are formed for climbing. There is only one species, viz. the torquilla. The colours of this bird are elegantly pencilled, though its plumage is marked with the plainest colours. The wryneck, Mr. Pennant apprehends, is a bird of passage, appearing with us in the spring before the cuckoo. Its note is like that of the kestril, a quick-repeated squeak; its eggs are white, with a very thin shell; it builds in the hollows of trees, making its nest of dry grass. It has a very whimsical way of turning and twisting its neck about, and bringing its head over its shoulders, whence it had its Latin name torquilla, and its English one of wryneck.

K.

K, or k, the tenth letter of our alphabet; as a numeral, denotes 250; and with a line over it, $\overline{K}$, 250000.

KÆMPFERIA, *zedoary*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the eighth order, scitamineæ. The corolla is sexpartite, with three of the segments larger than the rest, patulous; and one only bipartite. The species are, 1. The galanga, common galangal, or long zedoary. 2. The rotunda, or round zedoary. Both are perennial in root; but the leaves rise annually in spring, and decay in winter. They flower in summer; each flower is of one petal, tubulous below, but plain above, and divided into six parts; they continue three or four weeks in beauty, but are never succeeded by seeds in this country. Both these plants must be potted in light rich mould, and always kept in the hot-house.

KALI, a genus of marine plants, which are burnt to procure mineral alkali.

KALMIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 18th order, bicornes. The calyx is quinquepartite; the corolla salver-shaped, formed with five nectariferous horns on the under or outer side; the capsule quinquelocular. Of this genus there are four species. Those chiefly in cultivation with us are,

1. The latifolia, a most beautiful shrub, which rises usually to the height of five or six feet, and sometimes twice that height in its native places. The flowers grow in bunches on the tops of the branches to footstalks three inches long; they are white, stained with purplish red, consisting of one petal in form of a cup, divided at the verge into five sections; in the middle are a stylus and 12 stamina, which, when the flower first opens, appear lying close to the sides of the cup at equal distances, their apices being lodged in 10 little hollow cells, which being prominent on the outside, appear as so many little tubercles. This plant is a native of Carolina, Virginia, and other parts of the northern continent of America, yet is not common, but found only in particular places; it grows on rocks hanging over rivulets and running streams, and on the sides of barren hills.

2. The angustifolia, rises to the height of about 16 feet, with evergreen leaves. The flowers grow in clusters, and when blown, appear white; but on a near view, are of a faint bluish colour, which as the flower decays grows paler.

KAOLIN, the name of an earth which is used as one of the two ingredients in oriental porcelain. See PORCELAIN.

KECKLE, or KECKLING, in the sea language, is the winding of old ropes about cables, to prevent them from galling.

KEDGING, in the sea-language, is when a ship is brought up or down a narrow river by means of the tide, the wind being contrary.

KEEL, the lowest piece of timber in a ship, running her whole length from the lower part of her stem to the lower part of her stern-post. Into it are all the lower futtocks fastened; and under part of it, a false keel is often used.

KEELSON, a principal timber in a ship, fayed withinside cross all the floor-timbers; and being adjusted to the keel without suitable scarfs, it serves to strengthen the bottom of the ship.

KEEP, in ancient military history, a kind of strong tower which was built in the centre of a castle or fort, to which the besieged retreated, and made their last efforts of defence. Of this description is the keep of Windsor castle.

KEEPER *of the great seal*, is a lord by his office, is styled lord-keeper of the great seal of Great Britain, and is always one of the privy council. All grants, charters, and commissions of the king under the great seal, pass through the hands of the lord-keeper, for without that seal many of those grants, &c. would be of no force, the king being, in the interpretation of the law, a corporation, and therefore passing nothing but by the great seal, which is also said to be the public faith of the kingdom, being in the highest esteem and reputation. Whenever there is a lord-keeper, he is invested with the same place, authority, pre-eminence, jurisdiction, or execution of laws, as the lord chancellor of Great Britain is vested with.

KEEPER *of the privy seal*. See PRIVY SEAL.

KEISELSCHIEFER. This mineral occurs usually in blocks and amorphous masses of different sizes; very often in the beds of rivers: colour various shades of grey: structure slaty: usually opaque: brittle: specific gravity from 2.880 to 2.415: infusible per se. This species is divided into two subspecies.

Keiselschiefer, common: colour blackish grey or greenish: often traversed by veins of quartz: surface smooth: texture compact: fracture splintery, or imperfectly conchoidal: composed according to Wiegleb of

75.00	silica
10.00	lime
4.58	magnesia
3.54	iron
5.02	inflammable matter
98.14	

Lydian stone is another species of keiselschiefer: commonly intersected by veins of quartz: fracture even: sometimes inclining to conchoidal: specific gravity 2.596: powder black: colour greyish black.

This, or a stone similar to it, was used by the ancients as a touchstone. They drew the metal to be examined along the stone, and judged of its purity by the colour of the metallic streak. On this account they called it βασανος, "the trier." They called it also Lydian-stone, because, as Theophrastus informs us, it was found most abundantly in the river Tmolus in Lydia.

KELP, in the glass trade, a term used for a sort of potass made use of in many of the glass works, particularly for the green glass. It is the calcined ashes of a

plant called by the same name; and in some places of sea-tangs or laces, a sort of thick-leaved fucus or sea-wrack. This plant is thrown on the rocks and shores in great abundance, and in the summer months is raked together and dried as hay in the sun and wind, and afterwards burned to the ashes called kelp.

KEMO, a shell found on the coast of Sumatra; it is sometimes three or four feet in diameter, as white as ivory. See Marsden's Hist. of Sumatra.

KENKS, in the sea-language, doublings in a rope or cable, when handed in and out, so that it does not run easy; or when any rope makes turns or twists, and does not run free in the block.

KERATOPHYTUM, in natural history. See CORALLINES.

KERMES. See COCCUS.

KERMES MINERAL, a compound of sulphuret of antimony and potass.

KETCH, in naval architecture, a vessel with two masts, usually applied to one carrying bombs, or rather mortars.

KEVEL, in ship-building, a piece of plank fayed against the quickwork on the quarter-deck, in the shape of a semicircle; about which the running rigging is belaid.

KEY, in music, a fundamental note or tone to which the whole of a movement has a certain relation or bearing, to which all its modulations are referred and accommodated, and in which it both begins and ends. There are but two species of keys, one of the major, and one of the minor mode; all the keys in which we employ sharps or flats being deduced from the natural keys of C major, and A minor, of which indeed they are only transpositions.

KEY-STONE. See ARCHITECTURE.

KEYS. See ORGAN, HARPSICHORD, &c.

KIDKNAPPING, is the forcible taking and carrying away a man, woman, or child, from their own country, and sending them to another. This is an offence at common law, and punishable by fine, imprisonment, and pillory.

By stat. 11 and 12 W. III. c. 7, if any captain of a merchant vessel shall during his being abroad force any person on shore, and wilfully leave them behind, or refuse to bring home all such men as he carried out, if able and desirous to return, he shall suffer three months imprisonment. Exclusive of the above punishment for this as a criminal offence, the party may recover upon an action for compensation in damages for the civil injury.

KIDNEYS. See ANATOMY.

KIFFEKIL. This mineral is dug up near Konie in Natolia, and is employed in forming the bowls of Turkish tobacco-pipes. The sale of it supports a monastery of dervises established near the place where it is dug. It is found in a large fissure six feet wide, in grey calcareous earth. The workmen assert that it grows again in the fissure, and puffs itself up like froth. This mineral, when fresh dug, is of the consistence of wax; it feels soft and greasy; its colour is yellow; its specific gravity 1.600: when thrown on the fire it sweats, emits a fetid vapour, becomes hard, and perfectly white.

According to the analysis of Klaproth, it is composed of

50.50	silica
17.25	magnesia
25.00	water
5.00	carbonic acid
.50	lime.
98.25	

KIGGELARIA, a genus of the decandria order, in the diœcia class of plants, and in the natural method ranking under the 37th order, columniferæ. The male calyx is quinquepartite; the corolla pentapetalous; there are five trilobous glandules; the antheræ are perforated at top; the female calyx and corolla as in the male; there are five styles; the capsule unilocular, quinquevalved, and polyspermous. There is but one species, viz. the Africana. As this is a native of warm climates, it must be constantly kept in a stove in this country. It is propagated by seeds, layers, or cuttings, though most readily by seeds.

KILDERKIN, a liquid measure containing two firkins, or 18 gallons.

KINDRED. See DESCENT.

KING, signifies him who has the highest power and absolute rule over the whole land; and therefore the king is, intendment of law, cleared of those defects which common persons are subject to; for he is always supposed to be of full age, though ever so young. He pardons life and limb to offenders against the crown and dignity, except such as he binds himself by oath not to forgive. The law ascribes to his majesty, in his political capacity, an absolute immortality. The king never dies. For immediately on the decease of the reigning prince in his natural capacity, his imperial dignity, by act of law, without any interregnum or interval, is vested at once in his heir, who is eo instanti king to all intents and purposes. And so tender is the law of supposing even a possibility of his death, that his natural dissolution is generally called his demise, an expression signifying merely a transfer of property. Plowd. 177.

By the articles of the union of the two kingdoms of England and Scotland, all papists, and persons marrying papists, are for ever excluded from the imperial crown of Great Britain; and in such case, the crown shall descend to such person being a protestant, as should have inherited the same, in case such papist, or person marrying a papist, was naturally dead. 5 Anne, c. 8.

KING'S BENCH. The king's bench is the supreme court of common law in the kingdom, and is so called because the king used to sit there in person; it consists of a chief justice, and three puisne justices, who are by their office the sovereign conservators of the peace, and supreme coroners of the land.

This court has a peculiar jurisdiction, not only over all capital offences, but also over all other misdemeanours of a public nature, tending either to a breach of the peace, or to oppression, or faction, or any manner of misgovernment. It has a discretionary power of inflicting exemplary punishment on offenders, either by fine, imprisonment, or other infamous punishment, as the nature of the crime, considered in all its circumstances, shall require.

The jurisdiction of this court is so transcendant, that it keeps all inferior jurisdictions within the bounds of

their authority; and it may either remove their proceedings to be determined here, or prohibit their progress below: it superintends all civil corporations in the kingdom; commands magistrates and others to do what their duty requires, in every case where there is no specific remedy; protects the liberty of the subject, by speedy and summary interposition; takes cognizance both of criminal and civil causes; the former in what is called the crown side, or crown office; the latter in the plea side of the court.

This court has cognizance on the plea side of all actions of trespass, or other injury alleged to be committed vi et armis; of actions for forgery of deeds, maintenance, conspiracy, deceit, and actions on the case which allege any falsity or fraud.

In proceedings in this court, the defendant is arrested for a supposed trespass, which in reality he has never committed; and being thus in the custody of the marshal of this court, the plaintiff is at liberty to proceed against him for any other personal injury, which surmise of being in the custody of the marshal, the defendant is not at liberty to dispute.

This court is likewise a court of appeal; into which may be removed, by writ of error, all determinations of the court of common pleas, and of all inferior courts of record in England.

King's bench prison. King's bench new rules. East. 30 G. III. it is ordered by the court, that from and after the first day of Trinity term next, the rule made in the sixth year of the reign of king George I. and all other rules for establishing the rules of the king's bench prison, shall be, and the same are hereby repealed. And it is farther ordered, that from and after the said first day of Trinity term next, the rules of the king's bench prison shall be comprized within the bounds following, exclusive of the public houses hereinafter mentioned; that is to say, from Great Camber-court in the parish of St. George the Martyr, in the county of Surry, along the north side of Dirty-lane, and Melancholy-walk, to Blackfriar's-road, along the western side of the said road to the obelisk, and thence along the south-west side of the London-road, round the direction post in the centre of the roads, near the public house known by the sign of the Elephant and Castle, and thence along the eastern side of Newington causeway to Great Cumber-court aforesaid: and it is also ordered, that the new gaol Southwark, and the highway, exclusive of the houses on each side of it, leading from the king's bench prison to the said new gaol, shall be within and part of the said rules. And it is lastly ordered, that all taverns, victualling-houses, ale-houses, and wine vaults, and houses or places licensed to sell gin, or other spirituous liquors, shall be excluded out of, and deemed no part of the said rules. It is ordered, that from and after the first day of Trinity term next, no prisoner in the king's bench prison, or within the rules thereof, shall have, or be entitled to have, day rules above three days in each term. And it is further ordered, that every such prisoner having a day rule, shall return within the walls or rules of the said prison, at or before nine o'clock in the evening of the day on which such rule shall be granted.

King's palace. The limits of the king's palace at Westminster extend from Charing-cross to Westminster-hall, and shall have such privileges as the ancient palaces. 28 H. VIII. c. 12.

King's fisher. See Alcedo.

KLINGSTEIN: this mineral composes whole mountains. They are usually insulated; and like basalt, show a tendency to assume the form of four-sided prisms. Its colour is usually deep grey, of various shades; but most commonly greenish. Sometimes various shades appear together, which gives it the appearance of being spotted. Found not only constituting mountains, but also in globular masses, &c. Internal lustre arises chiefly from some crystals of hornblende and felspar which it contains. Structure slaty. Texture compact. Fracture usually splintery; sometimes conchoidal. Brittle. Gives a clear sound when struck with a hammer. Specific gravity 2.575. Powder light grey. Melts easily into a glass. A specimen analysed by Klaproth yielded

57.25	silica
23.50	alumina
2.75	lime
3.25	oxide of iron
0.25	oxide of manganese
8.10	soda
3.00	water
98.10	

KLEINHOVIA, a genus of the class and order gynandria decandria; the calyx is five-leaved; corolla five-petalled; nect. bell-shaped; caps. inflated, five-lobed. There is one species, a tree of Java.

KNAPSACK, a rough leather or canvas bag, which is strapped to an infantry soldier's back when he marches, and which contains his necessaries. Square knapsacks are supposed to be most convenient. They should be made with a division to hold the shoes, blacking-balls, and brushes, separate from the linen. White goat-skins are sometimes used, but we do not conceive them to be equal to the painted canvas ones. Soldiers are put under stoppages for the payment of their knapsacks, which after six years become their property.

KNAUTIA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 48th order, aggregatæ. The common calyx is oblong, simple, quinqueflorous; the proper one simple, superior; the florets irregular; the receptacle naked. There are four species, chiefly annuals of the Levant.

KNEE. See Anatomy.

Knee, in a ship, a crooked piece of timber, bent like a knee, used to bend the beams and futtocks together, by being bolted fast into them both. These are used about all the decks.

KNEES, *carling*, in a ship, those timbers which extend from the sides to the hatchway, and bear up the deck on both sides.

KNIGHT, properly signifies a person, who, for his virtue and martial prowess, is by the king raised above the rank of gentleman into a higher class of dignity and honour. The ceremonies at the creation of knights have been various; the principal was a box on the ear, and a stroke with a sword on the shoulder; they put on him a shoulder-belt, and a gilt sword, spurs, and other military accoutrements; after which, being armed as a knight, he was led to the church in great pomp. Camden describes

the manner of making a knight-bachelor, which is the lowest, though the most ancient order of knighthood, to be thus: the person kneeling was gently struck on the shoulder by the prince, and accosted in these words, "rise," or "be a knight in the name of God." For the several kinds of knights among us, see BANNERET, BARONET, BATH, GARTER, &c.

KNIGHTS *of the shire*, or KNIGHTS *of parliament*, in the British polity, are two knights or gentlemen of estate, who are elected on the king's writ, by the freeholders of every county, to represent them in parliament. The qualification of a knight of the shire is to be possessed of 600*l.* per ann. in a freehold estate. Their expenses during their sittings were by a statute of Henry VIII. to be defrayed by the county; but this is now never required.

KNIGHT-MARSHAL, an officer in the king's household, who has jurisdiction and cognizance of any transgression within the king's household and verge; as also of contracts made there, whereof one of the house is party.

KNIGHTS, in a ship, two thick short pieces of wood, commonly carved like a man's head, having four shivers in each, three for the halyards, and one for the top-ropes to run in; one of them stands fast bolted on the beams abaft the foremast, and is therefore called the fore-knight; and the other, standing abaft the mainmast, is called the main-knight.

KNOXIA, a genus of the class and order tetrandria monogynia. The corolla is one-petalled, funnel-form; seeds two-grooved. There is one species, a herb of Ceylon.

KOENIGIA, a genus of the trigynia order, belonging to the triandria class of plants. The calyx is triphyllous; there is no corolla, and but one ovate and naked seed.

KORAN. See ALCORAN.

KUPFERNICKEL, is a sulphuret of nickel, and is generally compounded of nickel, arsenic, and sulphuret of iron.

KURTUS, a genus of fishes of the order jugulares; the generic character of which is, body broad, carinated both above and below, with greatly elevated back; gill-membrane two-rayed. The genus kurtus, instituted by Dr. Bloch, consists at present of a single species only. This is a native of the Indian seas; and is supposed to feed on shell-fish, small cancri, and other sea insects, the remains of which were observed in the stomach of the specimen examined by Dr. Bloch. The length of this fish was about ten inches, including the tail, and its greatest breadth something more than four inches; its shape is deep or broad, the sides being much compressed, and the back rising very high in the middle. The colour of the whole body is silvery, as if covered with foil, without any appearance of scales; the back is tinged with gold-colour and marked by three or four black spots on its ridge, and the fins have a reddish cast.

L.

L, or l, the eleventh letter of our alphabet, as a numeral, denotes 50; and with a line over it, thus, $\overline{L}$, 50000.

LA, in music, the syllable by which Guido denoted the last sound of each hexachord: if it begins in C, it answers to our A; if in G to E; and if in F to D.

LABARUM, in Roman antiquity, the standard borne before the Roman emperors: being a rich purple streamer, supported by a spear.

LABDANUM, or LADANUM. This resin is obtained from the cystus creticus, a shrub which grows in Syria and the Grecian islands. The surface of the shrub is covered with a viscid juice, which when concreted forms ladanum. It is collected while moist by drawing over it a kind of rake with thongs fixed to it; from these it is afterwards scraped with a knife. The best is in masses almost black, and very soft, having a fragrant odour and a bitterish taste. When dissolved in alcohol, it leaves behind it a little gum. The specific gravity of this resin is about 1.18. See RESINS.

LABEL, in heraldry, a fillet usually placed in the middle along the chief of the coat, without touching its exremities.

LABEL of a circumferentor, a long thin brass ruler, with a sight at one end, and a centre-hole at the other; chiefly used with a tangent line to take altitudes.

LABORATORY and *Apparatus*, chemical. A chemical laboratory, though extremely useful, and even essential to all who embark extensively in the practice of chemistry, either as an art, or as a branch of liberal knowledge, is by no means required for the performance of those simple experiments which furnish the evidence of the fundamental truths of the science. A room that is well lighted, easily ventilated, and destitute of any valuable furniture, is all that is absolutely necessary for the purpose. It is even advisable that the construction of a regular laboratory should be deferred till the student has made some progress in the science; for he will then be better qualified to accommodate its plan to his own peculiar views and convenience.

It is scarcely possible to offer the plan of a laboratory, which will be suitable to every person, and to all situations; or to suggest any thing more than a few rules that should be generally observed. Different apartments are required for the various classes of chemical operations. The principal one may be on the ground floor; twenty-five feet long, fourteen or sixteen feet wide, and open to the roof, in which there should be contrivances for allowing the occasional escape of suffocating vapours. This will be destined chiefly for containing furnaces, both fixed and portable. It should be amply furnished with shelves and drawers, and with a large table in the centre, the best form of which is that of a double cross. Another apartment may be appropriated to the minuter operations of chemistry; such as those of precipitation on a small scale, the processes that require

merely the heat of a lamp, and experiments on the gases. In a third, of smaller size, may be deposited accurate balances, and other instruments of considerable nicety, which would be injured by the acid fumes that are constantly spread through a laboratory.

The following are the principal instruments that are required in chemical investigations; but it is impossible, without entering into very tedious details, to enumerate all that should be in the possession of a practical chemist.

1. Furnaces. These may either be formed of solid brick-work, or of such materials as admit of their removal from place to place. See FURNACE, and CHEMISTRY.

2. For containing the materials, which are to be submitted to the action of heat in a wind furnace, vessels called crucibles are employed. They are most commonly made of a mixture of fire-clay and sand, occasionally with the addition of plumbago, or black lead. The Hessian crucibles are best adapted for supporting an intense heat without melting; but they are liable to crack when suddenly heated or cooled. The porcelain ones made by Messrs. Wedgewood, are of much purer materials, but are still more apt to crack on sudden changes of temperature; and when used, they should therefore be placed in a common crucible of larger size, the interval being filled with sand. The black-lead crucibles resist very sudden changes of temperature, and may be repeatedly used; but they are destroyed when some saline substances (such as nitre) are melted in them, and are consumed by a current of air. For certain purposes crucibles are formed of pure silver or platina. Their form varies considerably; but it is necessary, in all cases, to raise them from the bars of the grate, by a stand. For the purpose of submitting substances to the continued action of a red heat, and with a considerable surface exposed to the air, a hollow arched vessel, with a flat bottom, termed a muffle, is commonly used. See CHEMISTRY.

3. Evaporating vessels should always be of a flat shape, so as to expose them extensively to the action of heat. They are formed of glass, or earthenware, and of various metals. Those of glass are with difficulty made sufficiently thin, and are often broken by changes of temperature; but they have a great advantage in the smoothness of their surface, and in resisting the action of most acid and corrosive substances. Evaporating vessels of porcelain, or Wedgewood's ware, are next in utility, are less costly, and less liable to be cracked. They are made both of glazed and unglazed ware. For ordinary purposes, the former are to be preferred: but the unglazed should be employed when great accuracy is required, since the glazing is acted on by several chemical substances. Evaporating vessels of glass, or porcelain, are generally bedded up to their edge in sand; but those of various metals are placed immediately over the naked fire. When the glass or porcelain vessel is very thin, and of small size, it may be safely placed on the ring of a brass stand, and the flame of Argand's lamp, cautiously regulated, may be applied beneath it. A lamp thus supported, so as to be raised or lowered at pleasure, on an upright pillar, to which rings of various diameters are adapted, will be found extremely useful; and when a strong heat is required, it is advisable to employ a lamp provided with double concentric wicks.

4. In the process of evaporation, the vapour for the most part is allowed to escape; but in certain chemical processes, the collection of the volatile portion is the principal object. This process is termed distillation. See DISTILLATION.

The common still, however, can only be employed for volatilizing substances that do not act on copper, or other metals, and is, therefore, limited to very few operations, and on that account alembics and retorts are necessary. See CHEMISTRY.

In several instances, the substance raised by distillation, is partly a condensible liquid, and partly a gas, which is not condensed till it is brought into contact with water. To effect this double purpose, a series of receivers termed Woulfe's apparatus is employed. See CHEMISTRY.

When a volatile substance is submitted to distillation, it is necessary to prevent the escape of the vapour through the junctures of the vessels; and this is accomplished by the application of lutes. The most simple method of confining the vapour, it is obvious, would be to connect the places of juncture accurately together by grinding; and accordingly the neck of the retort is sometimes ground to the mouth of the receiver. This, however, adds too much to the expense of apparatus to be generally practised.

When the distilled liquid has no corrosive property, (such as water, alcohol, ether, &c.) slips of moistened bladder, or of paper or linen spread with flour paste, white of egg, or mucilage of gum Arabic, sufficiently answer the purpose. The substance which remains, after expressing the oil from bitter almonds, and which is sold under the name of almond meal or flour, forms a useful lute, when mixed to the consistency of glaziers' putty, with water or mucilage.

For confining the vapour of acid or highly corrosive substances, the fat lute is well adapted. It is formed by beating perfectly dry and finely sifted tobacco-pipe clay with painters' drying-oil, to such a consistence that it may be moulded by the hand. The same clay, beaten up with as much sand as it will bear without losing its tenacity, with the addition of cut tow, or of horse-dung, and a proper quantity of water, furnishes a good lute, which has the advantage of resisting a considerable heat, and is applicable in cases where the fat lute would be melted or destroyed. Various other lutes are recommended by chemical writers; but the few that have been enumerated are found to be amply sufficient for every purpose. See LUTE.

On some occasions, it is necessary to protect the retort from too sudden changes of temperature by a proper coating. For glass retorts, a mixture of common clay or loam with sand, and cut shreds of flax, may be employed. If the distillation is performed by a sand heat, the coating needs not to be applied higher than that part of the retort which is bedded in sand; but if the process is performed in a wind furnace, the whole body of the retort, and that part of the neck also which is exposed to heat, must be carefully coated. To this kind of distillation, however, earthen retorts are better adapted; and they may be covered with a composition originally recommended by Mr. Willis. Two ounces of borax are to be dissolved in a pint of boiling water, and a sufficient quantity of slaked lime added to give it the thickness of

cream. This is to be applied by a painter's brush, and allowed to dry. Over this a thin paste is afterwards to be applied, formed of slaked lime and common linseed-oil, well mixed and perfectly plastic. In a day or two, the coating will be sufficiently dry to allow the use of the retort.

For joining together the parts of iron vessels used in distillation, a mixture of the finest China clay, with solution of borax, is well adapted. In all cases, the different parts of any apparatus made of iron should be accurately fitted by boring and grinding, and the above lute is to be applied to the part which is received into an aperture. This will generally be sufficient without any exterior luting; otherwise the lute of clay, sand, and flax, already described, may be used.

In every instance, where a lute or coating is applied, it is advisable to allow it to dry before the distillation is begun; and even the fat lute, by exposure to the air during one or two days after its application, is much improved in its quality. The clay and sand lute is perfectly useless, except it is previously quite dry. In applying a lute, the part immediately over the juncture should swell outwards, and its diameter should be gradually diminished on each side.

Besides the apparatus already described, a variety of vessels and instruments are necessary, having little resemblance to each other in the purposes to which they are adapted. Glass vessels are required for effecting solution, which often requires the application of heat, and sometimes for a considerable duration. In the latter case it is termed digestion, and the vessel called a mattrass is the most proper for performing it. When solution is quickly effected, a bottle, with a rounded bottom, may be used, or a common Florence-oil flask serves the same purpose extremely well, and bears without cracking, sudden changes of temperature. Glass rods, of various length, and spoons of the same material, or of porcelain, are useful for stirring acid and corrosive liquids; and a stock of cylindrical tubes of various sizes, is required for occasional purposes. It is necessary also to be provided with a series of glass measures, graduated into drachms, ounces, and pints.

Accurate beams and scales, of various sizes, with corresponding weights, some of which are capable of weighing several pounds, while the smaller size ascertain a minute fraction of a grain, are essential instruments in the chemical laboratory. So also are mortars of different materials, such as of glass, porcelain, agate, and metal. Wooden stands of various kinds for supporting receivers, should be provided. For purposes of this sort, and for occasionally raising to a proper height any article of apparatus, a series of blocks, made of well-seasoned wood, eight inches (or any other number) square, and respectively eight, four, two, one, and half an inch in thickness, will be found extremely useful; since by combining them in different ways, no less than thirty-one different heights may be attained.

The blowpipe is an instrument of much utility in chemical researches. A small one, invented by Mr. Pepys, with a flat cylindrical box for condensing the vapour of the breath, and for containing caps, to be occasionally applied with apertures of various sizes, is perhaps, the most commodious form. A blowpipe, which is supplied with air from a pair of double bellows, worked by the foot, may be applied to purposes that require both hands to be left at liberty, and will be found useful in blowing glass, and in bending tubes. The latter purpose, however, may be accomplished by holding them over an Argand's lamp with double wicks.

Laboratory, signifies also in military affairs, that place where all sorts of fire-works are prepared both for actual service, and for pleasure, viz. quick matches, fusees, portfires, grape-shot, case-shot, carcases, hand-grenades, cartridges, shells filled and fusees fixed, wads, &c.

LABRUS, a genus of fishes of the order thoracici: the generic character is, teeth strong and subacute: the grinders sometimes, as in the spari, convex and crowded; lips thick and doubled: rays of the dorsal fin, in some species, elongated into soft processes. Gill-covers unarmed and scaly.

Labrus hepatus, snout rather pointed: teeth small: palate furnished with a rough bone. Native of the Mediterranean, sometimes wandering into rivers. There are 41 species belonging to this genus, all of which are but imperfectly understood.

LABOURER. See Master and Servant.

LABYRINTH, in gardening, a winding mazy walk between hedges, through a wood or wilderness. The chief aim is to make the walks so perplexed and intricate, that a person may lose himself in them, and meet with as great a number of disappointments as possible. They are rarely to be meet with, except in great gardens; as Versailles, Hampton-court, &c.

LAC, an appellation given to several chemical preparations.

Lac. This resin exudes from the tree called the croton laciferum, when punctured by an insect. For the history of its formation, and the use to which it is applied by the insects, the reader is referred to the article Gum, &c. It is a substance of a deep-red colour verging on brown, and semitransparent, and distinguished by various names according to its purity. It possesses the properties of a resin, and is the basis of many varnishes, and of the finest kinds of sealing-wax.

Lac *sulphuris*, is obtained by precipitating sulphur, when in combination: it is composed of sulphur united to a little water.

LACHERNALIA, a genus of the class and order hexandria monogynia. The cor. is six-parted, three outer petals difform; caps. three-winged; cells many-seeded; seeds globular, affixed to the recept. There are twelve species, chiefly bulbs of the Cape.

LACTATS, in chemistry, a genus of salts but little known. 1. Lactat of potass, a deliquescent salt soluble in alcohol. 2. Lactat of soda. This salt does not crystallize. It is soluble in alcohol. 3. Lactat of ammonia. Crystals which deliquesce. Heat separates a great part of the ammonia before destroying the acid. 4. Lactat of barytes; lime; alumina; all deliquesce.

LACCIC acid. About the year 1786, Dr. Anderson of Madras mentioned, in a letter to the governor and council of that place, that nests of insects, resembling small cowry shells, had been brought to him from the woods by the natives, who ate them with avidity. These supposed nests he soon afterwards discovered to be the

coverings of the females of an undescribed species of coccus, which he shortly found means to propogate with great facility on several of the trees and shrubs growing in his neighbourhood.

On examining this substance, which he called white lac, he observed in it a very considerable resemblance to bees' wax; he noticed also, that the animal which secretes it provides itself by some means or other with a small quantity of honey, resembling that produced by our bees; and in one of his letters he complains, that the children whom he employed to gather it were tempted by its sweetness to eat so much of it, as materially to reduce the produce of his crop. Small quantities of this matter were sent into Europe in 1789, both in its natural state and melted into cakes; and in 1793 Dr. Pearson, at the request of sir Joseph Banks, undertook a chemical examination of its qualities, and his experiments were published in the Philosophical Transactions for 1794.

A piece of white lac, from 3 to 15 grains in weight, is probably produced by each insect. These pieces are of a grey colour, opaque, rough, and roundish. When white lac was purified by being strained through muslin, it was of a brown colour, brittle, hard, and had a bitterish taste. It melted in alcohol, and in water of the temperature of 145°. In many of its properties it resembles bees' wax, through it differs in others; and Dr. Pearson supposes that both substances are composed of the same ingredients, but in different proportions.

1. Two thousand grains of white lac were exposed in such a degree of heat as was just sufficient to melt them. As they grew soft and fluid, there oozed out 550 grains of a reddish watery liquid, which smelled like newly baken bread. To this liquid Dr. Pearson has given the name of laccic acid.

2. It possesses the following properties:

It turns paper stained with turnsole to a red colour.

After being filtered, it has a slightly saltish taste with bitterness, but it is not at all sour.

When heated, it smells precisely like newly baken hot bread.

On standing, it grows somewhat turbid, and deposits a small quantity of sediment.

Its specific gravity at the temperature of 60° is 1.025.

A little of it having been evaporated till it grew very turbid, afforded on standing small needle-shaped crystals in mucilaginous matter.

Two hundred and fifty grains of it were poured into a very small retort and distilled. As the liquor grew warm, mucilage-like clouds appeared; but as the heat increased they disappeared again. At the temperature of 200° the liquor distilled over very fast: a small quantity of extractive matter remained behind. The distilled liquor while hot smelled like newly baken bread, and was perfectly transparent and yellowish. A shred of paper stained with turnsole, which had been put into the receiver, was not reddened; nor did another which had been immersed in a solution of sulphat of iron, and also placed in the receiver, turn to a blue colour upon being moistened with the solution of potass.

About 100 grains of this distilled liquid being evaporated till it grew turbid, after being set by for a night, afforded acicular crystals, which under a lens appeared in a group not unlike the umbel of parsley. The whole of them did not amount to the quarter of a grain. They tasted only bitterish.

Another 100 grains being evaporated to dryness in a very low temperature, a blackish matter was left behind, which did not entirely disappear on heating the spoon containing it very hot in the naked fire; but on heating oxalic acid to a much less degree, it evaporated and left not a trace behind.

Carbonat of lime dissolved in this distilled liquid with effervescence. The solution tasted bitterish, did not turn paper stained with turnsole red, and on adding to it carbonat of potass a copious precipitation ensued. A little of this solution of lime and of alkali being evaporated to dryness, and the residuum made red-hot, nothing remained but carbonate of lime, and carbonat of potass.

This liquid did not render nitrat of lime turbid, but it produced turbidness in nitrat and muriat of barytes.

To 500 grains of the reddish-coloured liquor obtained by melting white lac, carbonat of soda was added till the effervescence ceased, and the mixture was nutralized; for which purpose three grains of the carbonat were necessary. During this combination a quantity of mucilaginous matter, with little carbonate of lime, was precipitated. The saturated solution being filtrated and evaporated to the due degree, afforded on standing deliquescent crystals, which on exposure to fire, left only a residum of carbonat of soda.

Lime-water being added to this reddish-coloured liquor produced a light purple turbid appearance; and on standing there were clouds just perceptible.

Sulphuret of lime occasioned a white precipitation, but no sulphureted hydrogen gas was preceptible by the smell.

Tincture of galls produced a green precipitation.

Sulphat of iron produced a purplish colour, but no precipitation; nor was any precipitate formed by the addition first of a little vinegar and then of a little potass to the mixture.

Acetat of lead occasioned a reddish precipitation, which redissolved on adding a little nitric acid.

Nitrat of mercury produced a whitish turbid liquor.

Oxalic acid produced immediately the precipitation of white acicular crystals owing probably to the presence of a little lime in the liquid.

Tartrat of potass produced a precipitation not unlike what takes place on adding tartaric acid to tartrat of potass; but it did not dissolve again on adding potass.

LACE, in commerce, a work composed of many threads of gold, silver, or silk, interwoven one with the other, and worked upon a pillow with spindles, according to the pattern designed; the open work being formed with pins, which are placed and displaced as the spindles are moved.

Method of cleaning gold-lace and embroidery when tarnished.—For this purpose alkaline liquors are by no means to be used; for while they clean the gold they corrode the silk, and change or discharge its colour. Soap also alters the shade, and even the species of certain colours. But spirit of wine may be used without any danger of its injuring either the colour or quality of the subject; and in many cases proves as effectual for restoring the lustre of the gold as the corrosive detergents.

But though spirit of wine is the most innocent materi-

al that can be employed for this purpose, it is not in all cases proper. The golden covering may be in some parts worn off; or the base metal, with which it has been iniquitously alloyed, may be corroded by the air, so as to leave the particles of the gold disunited; while the silver underneath, tarnished to a yellow hue, may continue a tolerable colour to the whole: in which cases it is apparent that the removal of the tarnish would be prejudicial to the colour, and make the lace or embroidery less like gold than it was before.

Lace, *bone*, a lace made of fine linen thread or silk, much in the same manner as that of gold and silver. The pattern of the lace is fixed upon a large round pillow, and pins being stuck into the holes or openings in the pattern, the threads are interwoven by means of a number of bobins, made of bone or ivory, each of which contains a small quantity of fine thread, in such a manner as to make the lace exactly resemble the pattern. There are several towns in England, and particularly in Buckinghamshire, that carry on this manufacture; but vast quantities of the finest laces have been imported from Flanders.

LACERTA, *lizard*, a genus of the amphibia class, and of the order of reptiles: the generic character is, body four-footed, elongated, tailed; without any secondary integument.

This numerous genus may be divided into the following sections, viz.

1. Crocodiles, furnished with very strong scales.
2. Guanas, and other lizards, either with serrated or carinated backs and tails.
3. Cordyles, with denticulated, and sometimes spiny scales, either on the body or tail, or both.
4. Lizards proper, smooth, and the greater number furnished with broad square scales or plates on the abdomen.
5. Chamæleons, with granulated skin, large head, long missile tongue, and cylindric tail.
6. Geckos, with granulated or tuberculated skin, and lobated feet, with the toes lamellated beneath.
7. Scinks, with smooth, fish-like, scales.
8. Salamanders, newts, or efts, with soft skins, and of which some are water-lizards.
9. Snake-lizards, with extremely long bodies, very short legs, and minute feet.

The above divisions neither are, nor can be, perfectly precise; since species may occur which may, with almost equal propriety, be referred to either of the neighbouring sections; but, in general, they will be found useful in the investigation of the species. The following are the most noted:

1. Lacerta crocodilus, or crocodile. The crocodile, so remarkable for its size and powers of destruction, has in all ages been regarded as one of the most formidable animals of the warmer regions. It is a native of Asia and Africa, but seems to be most common in the latter; inhabiting large rivers, as the Nile (see Plate LXXIV. Nat. Hist. fig. 237), the Niger, &c. and preying principally on fish, but occasionally seizing on almost every animal which happens to be exposed to its rapacity. The size to which the crocodile sometimes arrives is prodigious; specimens being frequently seen of 20 feet in length, and instances are commemorated of some which have exceeded the length of 30 feet. The armour with which the upper part of the body is covered may be numbered among the most elaborate pieces of nature's mechanism. In the full-grown animal it is so strong and thick as easily to repel a musket-ball; on the lower parts it is much thinner, and of a more pliable nature: the whole animal appears as if covered with the most regular and curious carved work: the colour of a full-grown crocodile is blackish-brown above, and yellowish-white beneath; the upper parts of the legs and the sides varied with deep yellow, and in some parts tinged with green. In the younger animals the colour on the upper parts is a mixture of brown and pale yellow, the under parts being nearly white: the eyes are provided with a nictitating membrane, or transparent moveable pellicle, as in birds: the mouth is of vast width, the rictus or gape having a somewhat fluxuous outline, and both jaws being furnished with very numerous sharp-pointed teeth, of which those about the middle part of each jaw considerably exceed the rest in size, and seem analogous to the canine teeth in the viviparous quadrupeds or mammalia: the number of teeth in each jaw is 30, or more; and they are so disposed as to alternate with each other when the mouth is closed: on taking out the teeth and examining the alveoli, it has been found that small teeth were forming beneath, in order to supply the loss of the others when shed: the auditory foramina are situated on the top of the head, above the eyes, and are moderately large, oval, covered by a membrane, having a longitudinal slit or opening, and thus in some degree resembling a pair of closed eyes: the legs are short, but strong and muscular: the fore feet have five toes, and are unwebbed: the hind feet have only four toes, which are united towards their base by a strong web: the two interior toes on each of the fore feet, and the interior one of the hind feet, are destitute of claws: on the other toes are strong, short, and curved claws: the tail is very long, of a laterally compressed form, and furnished above with an upright process, formed by the gradual approximation of two elevated crests proceeding from the lower part of the back.

The crocodile in a young state is by no means to be dreaded, its small size and weakness preventing it from being able to injure any of the larger animals: it therefore contents itself with fish and other small prey; and such as have occasionally been brought to Europe are so far from being formidable or ferocious, that they may be generally handled with impunity, and either from weakness, or the effect of a cold climate, seem much inclined to torpidity; but in the glowing regions of Africa, where it arrives at its full strength and power, it is justly regarded as the most formidable inhabitant of the rivers. It lies in wait near the banks, and snatches dogs and other animals, swallowing them instantly, and then plunging into the flood, and seeking some retired part, where it may lie concealed till hunger again invites it to its prey. In its manner of attack it is exactly imitated by the common lacerta palustris, or water-newt, which, though not more than four or five inches long, will with the greatest ease swallow an insect of more than an inch in length; and that at one single effort, and with a motion so quick, that the eye can scarcely follow it. It poises itself in the water, and having gained a convenient distance, springs with the utmost celerity on the insect, and

swallows it. If, therefore, a small lizard of four or five inches only in length can thus instantaneously swallow an animal of a fourth part of its own length, we need not wonder that a crocodile of 18, 20, or 25, feet long, should suddenly ingorge a dog or other quadruped.

Crocodiles, like the rest of the lacertæ, are oviparous: they deposit their eggs in the sand or mud near or on the banks of the rivers they frequent, and the young when hatched immediately proceed to the water; but the major part are said to be commonly devoured by other animals, as ichneumons, birds, &c. The egg of the common nilotic crocodile is not much larger than that of a goose, and in external appearance bears a most perfect resemblance to that of a bird; being covered with a calcareous shell, under which is a membrane. When the young are first excluded the head bears a much larger proportion to the body than when full-grown. The eggs, as well as the flesh of the crocodile itself, are numbered among the delicacies of some of the African nations, and are said to form one of their favourite repasts.

In the large rivers of Africa crocodiles are said to be seen swimming together in vast shoals, and resembling the trunks of so many large trees floating on the water. The negroes will sometimes attack and kill a single crocodile, by stabbing it under the belly, where the skin, at the interstices of the scales; is soft and flexible. It is also, in some countries, the custom to hunt the crocodile by means of strong dogs, properly trained to the purpose, and armed with spiked collars. It is likewise pretended, that in some parts of Africa crocodiles are occasionally tamed; and it is said that they form an article of royal magnificence with the monarchs of those regions, being kept in large ponds or lakes appropriated to their residence. We may add, that the ancient Romans exhibited these animals in their public spectacles and triumphs. Scaurus, during his ædileship, treated the people with a sight of five crocodiles, exhibited in a temporary lake; and Augustus introduced one into his triumph over Cleopatra, as well as several others, for the entertainment of the people.

2. Lacerta alligator. So very great is the general resemblance between this animal and the crocodile, that many naturalists have been strongly inclined to consider it as a mere variety, rather than a distinct species. The more accurate discrimination, however, of Blumenbach and some others seems in reality to prove that the alligator or American crocodile is specifically distinct from the nilotic, though the difference is not such as immediately to strike a general observer. The leading difference, if it be allowed to constitute a distinction of species, seems to be, that the head of the alligator is rather smooth on the upper part than marked with those very strong rugosities and hard carinated scales which appear on that of the crocodile; and that the snout is considerably flatter and wider, as well as more rounded at the extremity. The alligator arrives at a size not much inferior to that of the crocodile, specimens having been often seen of 18 or 20 feet in length.

"Though the largest and greatest numbers of alligators," says Catesby, "inhabit the torrid zone, the continent abounds with them 10 degrees more north, particularly as far as the river Neus in North Carolina, in the latitude of about 33 degrees, beyond which I have never heard of any, which latitude nearly answers to the northernmost parts of Africa, where they are likewise found. They frequent not only salt rivers near the sea, but streams of fresh water in the upper parts of the country, and in lakes of salt and fresh water, on the banks of which they lie lurking among reeds, to surprise cattle and other animals. In Jamaica, and many parts of the continent, they are found about 20 feet in length: they cannot be more terrible in their aspect than they are formidable and mischievous in their natures, sparing neither man nor beast they can surprise, pulling them down under water, that being dead, they may with greater facility, and without struggle or resistance, devour them. As quadrupeds do not so often come in their way, they almost subsist on fish; but as Providence, for the preservation, or to prevent the extinction of defenceless creatures, has in many instances restrained the devouring appetites of voracious animals, by some impediment or other, so this destructive monster, by the close connexion of his vertebræ, can neither swim nor run any other way than straight forward, and is consequently disabled from turning with that agility requisite to catch his prey by pursuit: therefore they do it by surprise in the water as well as by land; for effecting which nature seems in some measure to have recompensed their want of agility, by giving them a power of deceiving and catching their prey by a sagacity peculiar to them, as well as by the outer form and colour of their body, which on land resembles an old dirty log or tree, and in the water frequently lies floating on the surface, and there has the like appearance, by which, and his silent artifice, fish, fowl, turtle, and all other animals, are deceived, suddenly catched, and devoured.

"In Carolina they lie torpid from about October to March, in caverns and hollows in the banks of rivers, and at their coming out in the spring make an hideous bellowing noise. The hind part of their belly and tail are eaten by the Indians. The flesh is delicately white, but has so perfumed a taste and smell that I never could relish it with pleasure."

3. Lacerta gangetica. The gangetic crocodile is so strikingly distinguished both from the nilotic and the aligator by the peculiar form of the mouth, that it is hardly possible, even on a cursory view, to confound it with either of the former; the jaws being remarkably long, narrow, and perfectly straight, and the upper mandible terminated above an elevated tubercle. In a very young state the length and narrowness of the snout are still more conspicuous than the full-grown animal. The teeth are nearly double the number of those of the common crocodile, and are of equal size throughout the whole length of the jaws. This species is a native of India, and is principally seen in the Ganges, where it arrives at a size at least equal to the nilotic crocodile.

4. Lacerta iguana. Though the lizard tribe affords numerous examples of strange and peculiar form, yet few species are perhaps more eminent in this respect than the guana, which grows to a very considerable size, and is often seen of the length of three, four, and even five feet. It is a native of many parts of America and the West Indian islands, and is also said to occur in some parts of the East Indies. Its general colour is green, but with much variation in the tinge of different individuals:

it is generally shaded with brown in some parts of the body, and sometimes this is the predominating colour. The back of the guana is very strongly serrated; and this, together with the gular pouch, which it has the power of extending or inflating occasionally to a great degree. gives a formidable appearance to an animal otherwise harmless. It inhabits rocky and woody places, and feeds on insects and vegetables. It is itself reckoned an excellent food, being extremely nourishing and delicate; but it is observed to disagree with some constitutions. The common method of catching it is by casting a noose over its head, and thus drawing it from its situation; for it seldom makes an effort to escape, but stands looking intently at its discoverer, inflating its throat at the same time in an extraordinary manner.

The guana may be easily tamed while young, and is both an innocent and beautiful creature in that state.

5. Lacerta basiliscus. The basilisk of the ancients, supposed to be the most malignant of all poisonous animals, and of which the very aspect was said to be fatal, is a fabulous existence, to be found only in the representations of painters and poets.

But the animal known in modern natural history by this name is a species of lizard, of a very singular shape, and which is particularly distinguished by a long and broad wing-like process or expansion continued along the whole length of the back, and to a very considerable distance on the upper part of the tail, and furnished at certain distances with internal radii analogous to those in the fins of the fishes, and still more so to those in the wings of the draco volans, or flying lizard. This process is of a different elevation in different parts, so as to appear strongly sinuated and indented, and is capable of being either dilated or contracted at the pleasure of the animal. The occiput or hind part of the head is elevated into a very conspicuous pointed hood or hollow crest.

Notwithstanding its formidable appearance the basilisk is a perfectly harmless animal, and, like many other of the lizard tribe, resides principally among trees, where it feeds on insects, &c. The colour of the basilisk is a pale cinereous brown, with some darker variegations towards the upper part of the body. It is principally found in South America, and sometimes considerably exceeds the length before mentioned, measuring three feet, or even more, from the nose to the extremity of the tail. It is said to be an animal of great agility, and is capable of swimming occasionally with perfect ease, as well as of springing from tree to tree by the help of its dorsal crest, which it expands in order to support its flight.

6. Lacerta calotes. This species is considerably allied to the common guana in habit or general appearance; but is of much smaller size, rarely exceeding the length of a foot and a half from the tip of the nose to the extremity of the tail. It is also destitute of the very large gular pouch, so conspicuous in that animal; instead of which it has merely a slight inflation or enlargement on that part. In colour it occasionally varies, like most of this tribe; but it is commonly of an elegant bright blue, variegated by several broad, and somewhat irregular white or whitish transverse bands on each side of the body and tail. It is a native of the warmer regions both of Asia and Africa, and is found in many of the Indian islands, and particularly in Ceylon, in which it is common. According to the count de Cepede it is also found in Spain, &c. and is said by that author to wander about the top of houses in quest of spiders; and he observes, that it is even reported to prey on rats, and to fight with small serpents in the manner of the common green lizard and some others. See Plate LXXIV. Nat. Hist. fig. 256.

7. Lacerta monitor. The monitor, or monitory lizard, is one of the most beautiful of the whole tribe, and is also one of the largest; sometimes measuring not less than four or five feet from the nose to the tip of the tail. Its shape is slender and elegant, the head being small, the snout gradually tapering, the limbs moderately slender, the tail laterally compressed, and insensibly decreasing towards the tip, which is very slender and sharp. Though the colours of this lizard are simple, yet such is their disposition, that it is impossible to survey their general effect without admiration. In this respect, however, the animal varies perhaps more than most others of its tribe. It is commonly black, with the abdomen white, the latter colour extending to some distance up the sides, in the form of several pointed bands, besides which the whole body is generally ornamented by several transverse bands consisting of white annular spots, while the head is marked with various streaks of the same colour, the limbs with very numerous round spots, and the tail with broad, distant, transverse bands. It is a native of South America, where it frequents woody and watery places; and, if credit may be given to the reports of some authors, is of a disposition as gentle as its appearance is beautiful. It has even gained the title of monitor, salvaguarda, &c, from its pretended attachment to the human race, and it has been said that it warns mankind of the approach of the aligator by a loud and shrill whistle.

Cordyles, with either denticulated or spiny scales on the body or tail, or both.

8. Lacerta pelluma, is one of the middle sized lizards; the total length being nearly two feet, and the length of the body and tail nearly equal. It is a native of Chili, where it is said to inhabit hollows under ground. It is covered on the upper parts with very minute scales, and is beautifully variegated with green, yellow, blue, and black: the under parts are of a glossy yellowish-green: the tail long and verticillated by rows of rhomboidal scales. The skin of this lizard is said to be used by the Chilians for the purpose of a purse.

9. Lacerta stellio, is remarkable for the usually rough or hispid appearance of its whole upper surface; both body, limbs, and tail, being covered with pointed scales, projecting here and there to a considerable distance beyond the surface, so that it appears muricated with spines: the tail is rather short than long, and is verticillated with rows of pointed scales. The general colour of the animal is a pale blueish-brown, with a few deeper and lighter transverse variegations: its general length is about eight inches. It is a native of many parts of Africa.

Lizards proper, smooth, and the greater number furnished with broad square plates or scales on the abdomen.

10. Lacerta agilis, green lizard, is found in all the warmer parts of Europe, and seems pretty generally diffused over the ancient continent. It sometimes arrives at a very considerable size, measuring more than two feet to the extremity of the tail: its more general

length, however, is from 10 to 15 inches. In its colours it is the most beautiful of all the European lacertæ, exhibiting a rich and varied mixture of darker and lighter green, interspersed with specks and marks of yellow, brown, blackish, and even sometimes red. The green lizard is found in various situations, in gardens, about warm walls, buildings, &c. and is an extremely active animal, pursuing with great celerity its insect prey, and escaping with great readiness from pursuit when disturbed. If taken, however, it is soon observed to become familiar, and may even be tamed to a certain degree; for which reason it is considered as a favourite animal in many of the warmer parts of Europe. It appears to run into numerous varieties both as to size and colour; but in all these states the particular characteristics of the species are easily ascertained.

11. Lacerta bullaris, red-throat lizard. This, according to Catesby, is usually six inches long, and of a shining grass-green colour. It is common in Jamaica, frequenting hedges and trees, but is not seen in houses: when approached it swells its throat into a globular form, the protruded skin on that part appearing of a bright-red colour, which disappears in its withdrawn or contracted state: this action is supposed to be a kind of menace, in order to deter its enemy; but it is incapable of doing any mischief by its bite or otherwise. See Plate LXXIV. Nat. Hist. fig. 235.

Chameleons, with granulated skin, missile tongue, &c.

12. Lacerta chamæleon. Few animals have been more celebrated by natural historians than the chameleon, which has been sometimes said to possess the power of changing its colour at pleasure, and of assimilating it to that of any particular object or situation. This, however, must be received with very great limitations; the change of colour which the animal exhibits varying in degree according to circumstances of health, temperature of the weather, and many other causes, and consisting chiefly in a sort of alteration of shades from the natural greenish or bluish grey of the skin into pale yellowish, with irregular spots or patches of dull red.

It is also to be observed, that the natural or usual colour of chameleons varies very considerably; some being much darker than others, and it has even been seen approaching to a blackish tinge. And occasional change of colour is likewise observable, though in a less striking degree, in some other lizards.

The general length of the chameleon, from the tip of the nose to the beginning of the tail, is about ten inches, and the tail is of nearly similar length, but the animal is found of various sizes, and sometimes exceeds the length above mentioned. It is a creature of a harmless nature, and supports itself by feeding on insects; for which purpose the structure of the tongue is finely adapted, consisting of a long, missile body, furnished with a dilated and somewhat tubular tip, by means of which the animal seizes insects with great ease, darting out its tongue in the manner of a woodpecker, and retracting it instantaneously with the prey secured on its tip. It can also support a long abstinence, and hence arose the popular idea of the chameleon being nourished by air alone. It is found in many parts of the world, and particularly in India and Africa. It is also sometimes seen in the warmer parts of Spain and Portugal.

The general or usual changes of colour in the chameleon, are from a bluish ash-colour, (its natural tinge) to a green and sometimes yellowish colour, spotted unequally with red. If the animal is exposed to a full sunshine, the unilluminated side generally appears, within the space of some minutes, of a pale yellow, with large roundish patches or spots of red-brown. On reversing the situation of the animal, the same change takes place in an opposite direction; the side which was before in the shade now becoming either brown or ash-colour, while the other side becomes yellow and red; but these changes are subject to much variety both as to intensity of colours and disposition of spots.

Besides the common chameleon, different races appear to exist, which are principally distinguished by their colour, and the more or less elevated state of the angular or crested part of the head. These, which Linnæus was content to consider as varieties, are now raised to the dignity of species, and are so distinguished in the Gmelinian edition of the Systema Naturæ.

Geckos, with granulated or tuberculated skin, lobated feet, and toes lamellated beneath.

13. Lacerta gecko. The gecko, said to be so named from the sound of its voice, which resembles the above word uttered in a shrill tone, is a native of many parts of Asia and Africa, as well as of some of the warmer regions of Europe. It is one of the middle-sized lizards, measuring, in general, about a foot in length, or rather more. It is of a thicker and stouter form than most other lizards, having a large and somewhat triangular flattish head, covered with small scales, a wide mouth, large eyes, minute teeth, and a broad flat tongue. The limbs are of moderate length, and the feet are of a broader form than the rest of the genus.

The gecko inhabits obscure recesses, caverns, old walls, trees, &c. and wanders about chiefly on the approach of rain. It is considered as of a poisonous nature, a highly acrimonious kind of fluid exuding from the lamellæ of the feet, which remaining on the surface of fruit or any other edible substance is often productive of troublesome symptoms to those who happen to swallow it. From the peculiar structure of its feet, the gecko can readily adhere to the smoothest surfaces. The general colour of the animal is pale brown, with a few irregular dusky or bluish variegations; but in those which inhabit the warmer regions of the globe, this colour seems to be exalted into a much more brilliant appearance.

14. Lacerta fimbriata. This remarkable species seems to have been first described by the count de Cepede, who informs us that it appears in some degree to connect the chameleon, the gecko, and the water-newts; the head, skin, and general form of the body, resembling those of the chameleon; the tail that of the water-newts, being of a compressed form, though in a different manner (not vertically but horizontally flattened), while the feet resemble those of the gecko. The largest specimen examined by the count de Cepede measured about eight inches and six lines in length, of which the tail measured two inches and four lines.

The colour of this animal is not constant or permanent, as in most lizards, but variable, as in the chameleon, presenting successively different shades of red, yel-

low, green, and blue. This variation of colour is, however, confined to the upper surface of the animal; the lower always continuing of a bright yellow. The changes, we are informed, have been observed in the living animal by Mons. Bruyeres, in his native country, viz. Madagascar, where it is not very uncommon, and where, though a harmless animal, it is held in great abhorrence by the natives, who consider it as of a poisonous nature, and fly from it with precipitation; pretending that it darts on their breast, and adheres with such force by its fringed membrane, that it cannot be separated from the skin without the assistance of a razor. The principal cause of this popular dread of the animal, is its habit of running open-mouthed towards the spectator, instead of attempting to escape when discovered. Its chief residence is on the branches of trees, where it lives on insects, holding itself secure by coiling its tail, short as it is, half round the twig on which it sits. It chiefly appears in rainy weather, when it moves with considerable agility, often springing from bough to bough. On the ground it walks but slowly, the fore legs being shorter than the hinder.

Scinks, with round fish-like scales.

15. Lacerta scincus, or officinal scink. The scink is one of the middle-sized or smaller lizards, and is a native of many of the eastern parts of the world. It abounds in Lybia, Syria, Egypt, and Arabia, frequenting moderately dry and sandy soils, and growing to the length of six or seven inches, or even sometimes more. The head of the scink is rather small than large, the body thick and round, the tail in general considerably shorter than the body. The whole animal is of a pale yellowish-brown colour, with a few broad, dusky, transverse undulations or zones, and is uniformly covered with moderately large or fish-like scales, lying extremely close and smooth, so that the surface has a glossy or oily appearance. It is an animal of harmless manners, and, like most other lizards, supports itself on the various insects which wander about the regions it inhabits.

This animal was once in high estimation as an article in the materia medica, and the flesh, particularly of the belly, was supposed to be diuretic, alexipharmic, restorative, and useful in leprous and many other cases; but whatever virtues it may possess when used fresh, it is not considered as of any importance when in its dried or imported state, and while it continued to be used in practice served only to increase the number of ingredients in that curious remnant of what Dr. Lewis happily terms the wild exuberance of medical superstition in former ages, the celebrated confectio democratis, or mithridate.

Salamanders, Newts, or Efts.

16. Lacerta salamandra. The salamander, so long the subject of popular error, and of which so many idle tales have been recited by the more ancient naturalists, is an inhabitant of many parts of Germany, Italy, France, &c. but does not appear to have been discovered in England. It delights in moist and shady places, woods, &c. and is chiefly seen during a rainy season. In the winter it lies concealed in the hollows about the roots of old trees, in the subterraneous recesses, or in the cavities of old walls, &c. The salamander is easily distinguished by its colours; being of a deep shining black, variegated with large, oblong, and rather irregular patches of bright orange-yellow, which, on each side of the back, are commonly so disposed as to form a pair of interrupted longitudinal stripes: the sides are marked by many large transverse wrinkles, the intermediate spaces rising into strongly marked convexites; and the sides of the tail often exhibits a similar appearance: on each side of the back of the head are situated a pair of large tubercles, which are in reality the parotid glands: and are thus protuberant not only in some others of the lizard tribe, but in a remarkable manner in the genus rana: these parts, as well as the back and sides of the body, are beset in the salamander with several large open pores or foramina, through which exudes a peculiar fluid, serving to lubricate the skin, and which, on any irritation, is secreted in a more sudden and copious manner under the form of a whitish gluten, of a slightly acrimonious nature; and from the readiness with which the animal, when disturbed, appears to evacuate it, and that even occasionally to some distance, has arisen the long-continued popular error of the salamander's being enabled to live uninjured in the fire; which it has been supposed capable of extinguishing by its natural coldness and moisture: the real fact is, that like any of the cold and glutinous animals, as snails, &c. it, of course, is not quite so instantaneously destroyed by the force of fire as an animal of a drier nature would be. The general length of the salamander is about seven or eight inches, though it sometimes arrives at a much larger size. It is capable of living in water as well as on land, and is sometimes found in stagnant pools, &c. Its general pace is slow, and its manners torpid.

A strange error appears to have prevailed relative to the supposed poisonous nature of this animal; and the malignity of its venom has even been considered as scarcely admitting a remedy. It may be sufficient to observe, that the salamander is perfectly innoxious, and incapable of inflicting either wound or poison on any of the larger animals, though it appears, from the experiments of Laurenti, that the common small grey lizard (L. agil. var.) is poisoned by biting a salamander, and thus swallowing the secreted fluid of the skin; becoming almost immediately convulsed, and dying in a very short time afterwards.

The salamander is a viviparous species; producing its young perfectly formed, having been first hatched from internal eggs, as in the viper, and some other amphibia. It is said to retire to the water in order to deposit its young, which, at the first exclusion, are furnished with ramified branchial fins or processes on each side the neck, and which being merely temporary organs, are afterwards obliterated, as in the young of frogs and water-newts. The number of young produced at one birth by the salamander is said sometimes to amount to 30 or 40.

17. Lacerta vulgaris. This, which is the smallest of the British lizards, is altogether a terrestrial species. It is commonly seen in gardens, and not unfrequently in the neighbourhood of dunghills, &c. It also occasionally makes its way into cellars in the manner of the slug, the toad, &c.

18. Lacerta aquatica. This, which in England occurs

almost in every stagnant water, is a small species. Its general length is about three inches and a half, and it very rarely exceeds that of four inches at most.

The water-newts are remarkable for a high degree of reproductive power, and have been known to exhibit the restoration of their legs, tails, and even, according to Dr. Blumenbach, of the eyes themselves, after having been deprived of them by cutting.

Snake lizards, with extremely long bodies and short legs.

19. Lacerta chalcides. The chalcides is a native of many of the warmer parts of Europe, as well as of Africa, and is found of different sizes, from the length of a few inches to that of a foot, or even more. Its general length, however, seems to be eight or nine inches. The chalcides is an animal of a harmless nature, frequenting moist shady places, moving rather slowly, and feeding on insects, small worms, &c. It is a viviparous species, and is said to produce a great many young. The serpents to which it bears the nearest alliance in point of form, are those of the genus anguis, and particularly the A. fragilis, or common slow-worm.

20. Lacerta apus. A still nearer approach is made to the snake tribe by this large and singular lizard than even by the chalcides. It is a native of Greece, the southern parts of Siberia, and doubtless of many other parts of Europe and Asia, though it seems to have been but recently known to naturalists. It is found of the length of nearly three feet, and so perfectly resembles the general form of a large snake, that it is not without a near inspection that it is ascertained to belong to the race of lizards; being furnished merely with a pair of very short and somewbat acuminated processes by way of feet, situated at a vast distance from the fore parts of the body, nearly on each side the vent: the processes have no divisions or toes, but seem to form one simple projection, with a slight indenture only. The animal frequents moist and shady places, and appears to be of a harmless character.

LACHNEA, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking under the 31st order, veprecolæ. There is no calyx; the corolla is quadrifid, with the limb unequal; there is one seed a little resembling a berry. There are two species, shrubs of the Cape.

LACHRYMALIS, FISTULA. See SURGERY.

LACHRYMATORY, in antiquity, a vessel wherein were collected the tears of a deceased person's friends, and preserved along with the ashes and urn.

LACIS, a genus of the class and order polyandria digynia. There is no calyx or corolla. The filaments are winged on both sides below; the receptacle is girt with 12 spines; capsules ovate. There is one species, an aquatic of Guiana.

LACISTIMA, a genus of the monandria digynia class and order. The calyx is the scale of the ament; corolla four-parted; filaments bifid; berry pedicelled, one-seeded. There is one species, a shrub of Jamaica.

LACK OF RUPEES, is 100,000 rupees; which, supposing them standard, or siccas, at 2*s.* 6*d.* amounts to 12,500*l.* sterling.

LACQUERS, are varnishes applied upon tin, brass, and other metals, to preserve them from tarnishing, and to improve their colour. The basis of lacquers is a solution of the resinous substance called seed-lac in spirit of wine. The spirit ought to be very much concentrated, in order to dissolve much of the lac. For this purpose, some authors direct dry potass to be thrown into the spirit. This alkali attracts the water, with which it forms a liquid that subsides distinctly from the spirit at the bottom of the vessel. From this liquid the spirit may be separated by decantation. By this method the spirit is much concentrated; but, at the same time, it becomes impregnated with part of the alkali, which depraves its colour, and communicates a property to the lacquer of imbibing moisture from the air. These inconveniences may be prevented by distilling the spirit; or, if the artist has not an opportunity of performing that process, he may cleanse the spirit, in a great measure, from the alkali, by adding to it some calcined alum; the acid of which uniting with the alkali remaining in the spirit, forms with it a vitriolated tartar, which, not being soluble in spirit of wine, falls to the bottom together with the earth of the decomposed alum. To a pint of the purified spirit, about three ounces of powdered shell-lac are to be added; and the mixture to be digested during the same day with a moderate heat. The liquor ought then to be poured off, strained, and cleared by settling. This clear liquor is now fit to receive the required colour from certain resinous colouring substances, the principal of which are gamboge and annotto; the former of which gives a yellow, and the latter an orange colour. In order to give a golden colour, two parts of gamboge are added to one of annotto; but these colouring substances may be separately dissolved in the tincture of lac, and the colour required may be adjusted by mixing the two solutions in different proportions. When silver leaf or tin is to be lacquered, a larger quantity of the colouring materials is requisite than when the lacquer is intended to be laid on brass.

LACTEAL VESSELS. See ANATOMY.

LACTIC ACID. If milk be kept for some time it becomes sour. The acid which then appears in it was first examined by Scheele, and found by him to have peculiar properties. It is called lactic acid. In the whey of milk this acid is mixed with a little curd, some phosphat of lime, sugar of milk, and mucilage. All these must be separated before the acid can be examined. Scheele accomplished this by the following process:

Evaporate a quantity of sour whey to an eighth part, and then filtrate it: this separates the cheesy parts. Saturate the liquid with lime-water, and the phosphat of lime precipitates. Filtrate again, and dilute the liquid with three times its own bulk of water; then let fall into it oxalic acid, drop by drop, to precipitate the lime which it has dissolved from the lime-water; then add a very small quantity of lime-water, to see whether too much oxalic acid has been added. If there has, oxalat of lime immediately precipitates. Evaporate the solution to the consistence of honey, pour in a sufficient quantity of alcohohol, and filtrate again; the acid passes through dissolved in the alcohol, but the sugar of milk and every other substance remain behind. Add to the solution a small quantity of water, and distil with a small heat, the alcohol passes over, and leaves behind the lactic acid dissolved in water.

This acid is incapable of crystallizing: when evaporated to dryness, it deliquesces again in the air. When distilled, water comes over first, then a weak acid resembling the tartaric, then an empyreumatic oil mixed with more of the same acid, and, lastly, carbonic acid and carbureted hydrogen gas: there remains behind a small quantity of charcoal.

The combinations which this acid forms with alkalies, earths, and metallic oxides, are called lactats, which see.

All that is known concerning these salts are the following facts, ascertained by Scheele. When saturated with fixed alkalies, it gave salts which were deliquescent and soluble in spirit of wine. It formed deliquescent salts with ammonia, with barytes, with lime, and alumina; but with magnesia it formed small crystals, which however at length deliquesced. This acid had no effect on bismuth, cobalt, antimony, tin, mercury, silver, and gold. It dissolved zinc and iron; and it produced with these metals hydrogen gas. Zinc was the only metal with which it crystallized. Copper rendered this acid first slightly blue, then green, and lastly a deep blue; but no crystals were formed. Digested upon lead it became sweet, but did not crystallize.

LACTUCA, the *lettuce*, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the calyx imbricated, cylindrical, with a membranaceous margin; the pappus is simple, stipated, or stalked. There are 11 species, most of which are plants of no use, and never cultivated but in botanic gardens for variety. That commonly cultivated in the kitchen-garden is the sative, which includes the following varieties: 1. The common or garden lettuce. 2. Cabbage lettuce. 3. Silesia lettuce. 4. Dutch brown lettuce. 5. Aleppo, or sperm lettuce. 6. Imperial lettuce. 7. Green capuchin lettuce. 8. Versailles, or upright white cos lettuce. 9. Black cos. 10. Red cos. 11. Red capuchin lettuce. 12. Roman lettuce. 13. Prince lettuce. 14. Royal lettuce. 15. Egyptian cos lettuce.

The first of these sorts is very common in all gardens, and is commonly sown for cutting very young, to mix with other salad herbs in spring, and the second, or cabbage lettuce, is only this mended by culture. The first crop should be sown in February, in an open situation; the others at three weeks distance; but the later ones under covert, but not under the drippings of trees. The silesia, imperial, royal, black, white, and upright cos lettuces, may be first sown in the latter part of February or the beginning of March, on a warm light soil, and in an open situation: when the plants are come up, they must be thinned to 15 inches distance every way; they will then require no further care then the keeping them clear of weeds; and the black cos, as it grows large, should have its leaves tied together to whiten the inner part. Succeeding crops of these should be sown in April, May, and June; and towards the latter part of August they may be sown for a winter crop, to be preserved under glasses, or in a bed arched over with hoops and covered with mats. The most valuable of all the English lettuces are the white cos, or the Versailles; the Silesia; and the Egyptian cos. The brown Dutch and the green capuchin are very hardy, and may be sown late under walls, where they will stand the winter, and be valuable when no others are to be had. The red capuchin, Roman, and prince lettuce, are very early kinds, and are sown for variety; as are also the Aleppo ones for the beauty of their spotted leaves.

The several sorts of garden lettuces are very wholesome, emollient, cooling salad herbs, easy of digestion, and somewhat loosening the belly. Most writers suppose that they have a narcotic quality; and indeed in many cases contribute to procure rest: this they effect by abating heat, and relaxing the fibres. The seeds are in the number of the four lesser cold seeds.

LACUNAR. See Architecture.

LADDERS, *scaling*, in the military art, are used in scaling when a place is to be taken by surprise. They are made several ways: in England they are made of flat staves, so that they may move about their pins, and shut like a parallel ruler, for conveniently carrying them: the French make them of several pieces, so as to be joined together, and to be made of any necessary length: sometimes they are made of single ropes, knotted at proper distances, with iron hooks at each end, one to fasten them upon the wall above, and the other in the ground; and sometimes they are made with two ropes, and staves between them, to keep the ropes at a proper distance, and to tread upon. When they are used in the action of scaling walls, they ought to be rather too long than too short, and to be given in charge only to the stoutest of the detachment. The soldiers should carry these ladders with the left-arm passed through the second step, taking care to hold them upright close to their sides, and very short below, to prevent any accident in leaping into the ditch.

The first rank of each division, provided with ladders, should set out with the rest at the signal, marching resolutely with their firelocks slung, to jump into the ditch: when they are arrived they should apply their ladders against the parapet, observing to place them towards the salient angles rather than the middle of the curtin, because the enemy have less force there. Care must be taken to place the ladders within a foot of each other, and not to give them too much or too little slope, so that they may not be overturned or broken with the weight of the soldiers mounting upon them.

The ladders being applied, those who have carried them, and those who come after, should mount up, and rush upon the enemy sword in hand: if he who goes first happens to be overturned, the next should take care not to be thrown down by his comrade; but, on the contrary, immediately mount himself, so as not to give the enemy time to load his piece.

As the soldiers who mount first may be easily tumbled over, and their fall may cause the attack to fail, it would perhaps be right to protect their breasts with the fore parts of cuirasses; because if they can penetrate the rest may easily follow.

LADY'S smock. See Cardemine.

Lady's slipper. See Cypripedium.

LAETIA, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous, or none; the calyx is pentaphyllous; the fruit is unilocular and trigonal; the seeds have a pulpy arillus or coat. There are four species, natives of America. One of them, the apetala, or gum-wood,

Dr. Wright informs us, is very common in the woodlands and copses of Jamaica, where it rises to a considerable height and thickness. Pieces of the trunk or branches, suspended in the heat of the sun, discharge a clear turpentine or balsam, which concretes into a white resin, and which seems to be the same as gum sandarach. Pounce is there made of it, and our author is of opinion that it might be useful in medicine like other gums of the same nature.

LAGERSTROEMIA, a genus of the monogynia order, in the polyandria class of plants. The corolla is hexapetalous, and curled; the calyx sexfid, and campanulated; there are many stamina, and of these the six exterior ones thicker than the rest, and longer than the petals. There are four species, trees of the East Indies.

LAGOECIA, a genus of the monogynia order, in the pentandria class of plants. The involucrum is universal and partial; the petals bifid; the seeds solitary, inferior. There is one species, wild cummin, an annual of the Levant.

LAGUNEA, a genus of the class and order monadelphia polyandria. The calyx is simple, five-cusped; style simple; stigma peltated; capsule five-celled, five-valved. There are three species, shrubs of the East Indies and Surinam.

LAGURUS, a genus of the digynia order, in the triandria class of plants, and in the natural method raking under the fourth order, gramina. The calyx is bivalved with a villous awn, the exterior petal of the corolla terminated by two awns, with a third on its back retorted. There is one species, a grass of the south of Europe.

LAKES, certain colours made by combining the colouring matter of cochineal, or of certain vegetables, with pure alumine, or with oxide of tin, zinc, &c.

LAMA, the sovereign pontiff, or rather god, of the Asiatic Tartars, inhabiting the country of Barantola. The lama is not only adored by the inhabitants of the country, but also by the kings of Tartary, who send him rich presents, and go in pilgrimage to pay him adoration, calling him lama-congiu, *i. e.* God the everlasting father of heaven. He is never to be seen but in a secret place of his palace, amidst a great number of lamps, sitting cross-legged upon a cushion, and adorned all over with gold and precious stones; where, at a distance, they prostrate themselves before him, it not being lawful for any to kiss even his feet. He is called the great lama, or lama of lamas, that is, priest of priests. And to persuade the people that he is immortal, the inferior priests, when he dies, substitute another in his stead, and so continue to cheat from generation to generation. These priests persuade the people that the lama was raised from death many hundred years ago, that he has lived ever since, and will continue to live for ever.

LAMINÆ, in physiology, the thin plates of which many substances consist.

LAMIUM, *dead-nettle*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillatæ. The upper lip of the corolla is entire, arched, the under lip bilobous; the throat with a dent or tooth on each side of the margin. There are 13 species, of which only two, viz. the album, white archangel or dead-nettle, and the purpureum, or red archangel, deserve notice. The flowers of the first, which appear in April and May, have been particularly celebrated in uterine fluors, and other female weaknesses, and also in disorders of the lungs; but they appear to be of very weak virtue. The young leaves of both species are boiled and eaten in some places like greens.

LAMP, a vessel containing oil, with a lighted wick; of which there are an indefinite number made of various constructions for various purposes. We shall particularly notice Argand's lamp, and an improvement made upon it.

Argand's lamp is a very ingenious contrivance, and is the invention of a citizen of Geneva. The principle on which the superiority of the lamp depends, is the admission of a larger quantity of air to the flame than can be done in the common way. This is accomplished by making the wick of a circular form, by which means a current of air rushes through the cylinder on which it is placed, with great force; and, along with that which has access to the outside, excites the flame to such a degree that the smoke is entirely consumed. Thus both the light and heat are prodigiously increased, at the same time that there is a very considerable saving in the expense of oil, the consumption of the inflammable matter being exceedingly augmented by the quantity of air admitted to the flame; so that what in common lamps is dissipated in smoke is here converted into a brilliant flame.

This lamp is now very much in use, and is consequently well known.

We shall now describe an improvement of this neat invention. See Plate LXXV. Lamp, &c.

The upper compartment of the Plate represents an improved construction of Argand's lamp. A. fig. 1, is the reservoir for the oil, which unscrews at B; in order to fill it the oil is poured in at a hole *a*, fig. 4, in the lower end of the reservoir, which is covered, when the lamp is not burning, by a sliding collar, *b*, drawn up by a handle, *d*, which comes through a hole in the screw *e*, by which the reservoir is screwed in the short tube, E, fig. 1: there being no vent-holes in the upper part of the reservoir, A, to admit the air as the oil runs out, a bubble of air must enter the hole *a*, fig. 4, to supply the place of every drop of oil that comes out, when the reservoir, A, is screwed to the tube, E; the collar, *b*, being down, the oil runs out (the air being admitted from without through a small hole, *f*), till E is filled above the level of the hole, *a*, which prevents more air getting in; it remains in this state till by the burning of the lamp the oil is drawn down beneath the hole *a*, when it is filled again as before; by this means the lamp is always well supplied, but never overstocked with oil. From the bottom of the tube, E, fig. 1, the oil is conveyed by a pipe, D, to the lamp, the constitution of which is best explained in fig. 2; EF is the external tube of brass, which is supplied with oil by the pipe D; in the centre of this another tube, GG, is soldered, which is open at both ends: between these tubes is a cylinder of slightly wove cotton, *gg*, called the wick; this is fastened to a small cylinder of brass, *hh* (shown separately in fig. 3), which can be moved down and up as the wick burns. The wick is lowered or raised by turning round the cylinder, HH (shown separately in fig. 5), by means of its rim, II, fastened to the cylinder, HH, by three small rods, *ii*: the cylinder, HH, fig. 5, has a spiral groove, *kk*, cut obliquely round

it: the cylinder, hh, figs. 2 and 3, which goes within the cylinder, HH, has a small stub, l, projecting from it, which works into the groove, kk, fig. 5; the leaf, l, is long enough to project a small distance through the groove, kk, and when in its place takes against a small bead, n, fig. 2, fixed withinside the cylinder, FF, so as to prevent its turning, when HH is turned by its rim, II. By the above arrangement it is evident, that when the cylinder, HH, fig. 5, is turned round, and h is prevented from turning, the sides of the groove, k, will act as an inclined plane against the stub, l, and raise the cylinder h down or up, and the cotton wick, gg, with it. The rim, II, figs. 1, 2, and 5, has an ornamented border, L, round it, which serves to secure the glass chimney, c, from being overthrown. To prevent the cylinder, HH, from being lifted out by accident, it has a rim, o, figs. 2 and 5, at the lower end, cut through in one place to allow it to pass down by the bead, n; when it is below the end of the bead it cannot be raised, unless the notch in the rim, o, corresponds with the bead. When the wick, gg, figs. 1 and 5, is lighted, it rarefies the air in the glass chimney, O, and causes a draught through the tube, GG, to supply the inside of the wick, and also under the edge of the glass chimney to supply the outside: as the wick burns down it can be raised from time to time by turning the rim, I, as before described. The tube, FF, is always nearly full of oil, brought by the pipe, D. When it is required to put in a new wick, the glass chimney, O, is lifted off; the tube, hh, is screwed up to the top; by turning the rim, II, the tube, fig. 3, is then taken out, the old wick pulled off, and a new one is put round the small part, m, of the tube, which is then put in again, and screwed down to the proper depth for lighting the wick.

Rolling-Lamp, a machine, AB (see Pl. LXXVIII. Mis. fig. 145) with two moveable circles, DE, FG, within; whose common centre of motion and gravity is at K, where their axes of motion cross one another. If the lamp, KC, made pretty heavy, and moveable about its axis, HI, and whose centre of gravity is at C, be fitted within the inner circle, the common centre of gravity of the whole machine will fall between K and C; and by reason of the pivots A, B, D, E, H, I, will be always at liberty to descend: hence, though the whole machine be rolled along the ground, or moved in any manner, the flame will always be uppermost, and the oil cannot spill.

It is in this manner they hang the compass at sea; and thus should all the moon-lanterns be made that are carried before coaches, chaises, and the like.

Lamp-black, among colourmen. See Black.

LAMPREY. See Petromyzon.

LAMPYRIS, *glow-worm*, a genus of insects of the order coleoptera: the generic character is, antennæ filiform; wing-sheaths flexile; thorax flat, semiorbicular, concealing and surrounding the head; abdomen with the sides pleated into papillæ; female (in most species) wingless. The lampyris noctiluca, or common glow-worm, is a highly curious and interesting animal. It is seen during the summer months as late as the close of August, if the season is mild, on dry banks, about woods, pastures, and hedgeways, exhibiting, as soon as the dusk of the evening commences, the most vivid and beautiful phosphoric splendour, in form of a round spot of considerable size. The animal itself, which is the female insect, measures about three quarters of an inch in length, and is of a dull earthy brown colour on the upper parts, and beneath, more or less tinged with rose-colour, with the two or three last joints of the body of a pale or whitish sulphur-colour. It is from these parts that the phosphoric light abovementioned proceeds, which is of a yellow colour, with a very slight cast of green: the body, exclusive of the thorax, consists of ten joints or divisions. The larva, pupa, and complete female insect, scarcely differ perceptibly from each other in general appearance, but the phosphoric light is strongest in the complete animal. The glow-worm is a slow-moving insect, and in its manner of walking frequently seems to drag itself on by starts, or slight efforts. The male is smaller than the female, and is provided both with wings and wing-sheaths; and it is but rarely seen.

It is certain, that in some species of this genus the male, as well as the female, is luminous; as in the lampyris Italica, which seems to be a native of England also, though less common there than in the warmer parts of Europe. Aldrovandus describes the winged glow-worm as having its wing-shells of a dusky colour, and at the end of the body two brilliant fiery spots like the flame of sulphur. See Plate LXXVII. Nat. Hist. figs. 238, 239.

In the Philosophical Transactions for the year 1684, we find a paper by a Mr. Waller, describing the English flying glow-worm as of a dark colour, with the tail part very luminous. He maintains that both male and female of this species are winged, and that the female is larger than the male: the light of this insect was very vivid, so as to be plainly perceived even when a candle was in the room. Mr. Waller observed this species at Northaw, in Hertfordshire. From the figure given by this writer it appears to be about half an inch in length, which is much smaller than the common female glow-worm.

In Italy this flying glow-worm is extremely plentiful; and we are informed by Dr. Smith and other travellers, that it is a very common practice for the ladies to stick them by way of ornament in different parts of their head-dress during the evening hours.

The common or wingless glow-worm may be very successfully kept, if properly supplied with moist turf, grass, moss, &c. for a considerable length of time; and as soon as the evening commences, will regularly exhibit its beautiful effulgence, illuminating every object within a small space round it, and sometimes the light is so vivid as to be perceived through the box in which it is kept. This insect deposits its eggs, which are small and yellowish, on the leaves of grass, &c. There are 18 species of the lampyris.

LAND, in the sea language, makes part of several compound terms: thus *land-laid*, or to lay the land, is just to lose sight of it. *Land-locked*, is when land lies round the ship, so that no point of the compass is open to the sea: if she is at anchor in such a place, she is said to ride land-locked, and is therefore concluded to ride safe from the violence of winds and tides. *Land-mark*, any mountain, rock, steeple, tree, &c. that may serve to make the land known at sea. *Land is shut in*, a term used to signify that another point of land hinders the sight of that the ship came from. *Land to*, or the ship

lies land to, that is, she is so far from shore that it can only be just discerned. *Land-turn*, is a wind that in almost all hot countries blows at certain times from the shore in the night. *To set the land*, that is, to see by the compass how it bears.

LANDSCAPE. See PAINTING.

LAND-TAX, an ancient branch of the public revenue, the origin of which may be traced to the fines or commutations for military service, levied during the feudal system under the name of scutages. These are supposed to have been at first mere arbitrary compositions, as the king and the persons liable could agree; but the practice having been much abused, it was declared by Magna Charta, and afterwards repeatedly confirmed by acts of parliament, that no scutage should be imposed without the consent of the great men and commons, in parliament assembled. This tax was sometimes exacted under the name of hydage, or carrucage; but taxes on land came afterwards to be generally denominated subsidies, or assessments. During the Commonwealth, taxes on land were levied by monthly assessments; and commissioners were appointed in each county for rating the individuals. These assessments varied according to the exigencies of the times, from 35,000*l.* to 120,000*l.* a month; the assessments in Scotland were commonly 6000*l.* but sometimes 1000*l.* a month; in Ireland 9000*l.* a month. This mode of raising money was found so productive, that, with some little variations, it has under the denomination of land-tax ever since formed an important branch of the revenue.

The land-tax, till lately, differed from all the other branches of the public revenue (except part of the duties on malt), in being imposed annually, whereas other taxes have been granted either for a term of years, or, more commonly of late years, for ever; but though granted for only one year at a time, it has been regularly continued from year to year since the Revolution, having never been wholly taken off; but it has varied with respect to the rate at which it has been imposed, having been usually reduced during peace, and increased again in time of war, to answer, in part, the increased expenditure. In 1693 it was first raised to four shillings in the pound, upon a valuation given in the preceding year, and according to which it has continued to be raised to the present time, at the following rates:

In 1698 and 1699, at 3*s.*
1700, at 2*s.*
1701, at 3*s.*
1702 to 1712, at 4*s.*
1713 to 1715, at 2*s.*
1716, at 4*s.*
1717 to 1721, at 3*s.*
1722 to 1726, at 2*s.*
1727, at 4*s.*
1728 and 1729, at 3*s.*
1730 and 1731, at 2*s.*
1732 and 1733, at 1*s.*
1734 to 1739, at 2*s.*
1740 to 1749, at 4*s.*
1750 to 1752, at 3*s.*
1753 to 1755, at 2*s.*
1756 to 1766, at 4*s.*
1767 to 1770, at 3*s.*
1771, at 4*s.*
1772 to 1775, at 5*s.*
1776 to 1798, at 4*s.*

The sums to be raised at 4*s.* in the pound were stated, in the annual act, at 1,989,673*l.* 7*s.* 10¾*d.* for England, and 47,954*l.* 1*s.* 2*d.* for Scotland, making together 2,037,627*l.* 9*s.* 0¾*d.*; and upon credit of this assessment 2,000,000*l.* was annually borrowed of the Bank in anticipation of the tax, for which sum exchequer-bills were given them, which were to be discharged out of the produce of the tax as it came in; but the full amount of the assessment was seldom, if ever, collected, so that the nett payments into the exchequer always fell short of the sum borrowed on the credit thereof, exclusive of interest on the bills; and the deficiency was made good out of the supplies for the next year.

In 1798 the current value of the public funds having been unusually depressed for some time past, and apprehensions being entertained that the further increase of the funded debt would be attended with peculiar inconvenience, unless some mode was discovered of counteracting its effects, a project was adopted of offering the land-tax for redemption or sale. With this view an act was passed, making the land-tax a perpetual tax, from 25th March, 1799; and being thus converted into a permanent annuity, it was offered for sale to the proprietors of the lands upon which it was charged; or if they declined it, to any other person who chose to become a purchaser. In the first case it was considered as a redemption of the tax, the estate becoming in future wholly freed from it; in the latter case the purchaser became entitled to receive the land tax regularly from the receiver-general, half-yearly, on the 16th of March and 20th of September in every year. The consideration to be given in either case was not to be in money, but stock, either in the three per cent. consols., or three per cent. reduced, to be transferred to the commissioners for the reduction of the national debt. The quantity of stock to be transferred for redemption of the tax by persons interested in the land on which it was charged, was so much capital as yielded an annuity or dividend exceeding the amount of the tax to be redeemed by one-tenth part thereof; and the stock to be transferred for purchase of the tax by persons not interested in the land, was so much capital as yielded an annuity or dividend exceeding the tax to be purchased by one-fifth part thereof. Thus the amount of three per cent. stock to be transferred for 10*l.* per annum tax was 366*l.* 13*s.* 4*d.* for redemption, or 400*l.* for purchase.

This scheme was adopted with the view of facilitating the raising of money on loan, by absorbing a large quantity of floating stock, and thus raising the current price; while at the same time it would be attended with an increase of revenue. This at least was the avowed object of the measure, which it was estimated would be the means of redeeming or taking out of the market about 80,000,000*l.* of stock; the advantages offered by it were, however, by no means such as to induce a general approval of it, many persons subject to the tax declined redeeming it, and but few were inclined to become purchasers. The period first limited was several times extended, but the plan succeeded very imperfectly, and on the 1st February, 1803, the total amount of 3 per

cent. stock, which had been transferred for the redemption of land tax, was only 21,794,307*l.* 17*s.* 3*d.*

LANERIA, a genus of the hexandria monogynia class and order. The corolla is superior, woolly; the caps. three-celled. There is one species, a herb of the Cape.

LANGAYA, a genus of serpents: the generic character is, abdominal plates; caudal rings; terminal scales.

Langaya nasuta, snouted langaya. The genus langaya, consisting of a single species only, differs from all the rest of the serpent tribe in having the upper part or beginning of the tail marked into complete rings or circular divisions resembling those on the body of the amphisbena, while the extreme or terminal part is covered with small scales, as in the genus anguis.

The langaya nasuta, or long snouted langaya, is in length about two feet eight inches, and its greatest diameter about seven lines: the head is covered with large scales, but the snout, which is extremely long and sharp, projecting to a considerable distance beyond the lower jaw, is covered with very small scales; the teeth, in shape and disposition, resemble those of a viper. The natives of Madagascar are said to hold the langaya in great dread, considering it as a highly poisonous serpent.

LANGUED, in heraldry, expresses such animals whose tongue appearing out of the mouth, is borne of a different colour from that of the body.

LANIUS, the *shrike* or *butcher-bird;* a genus belonging to the order of accipitres, the characters of which are these: the beak is somewhat straight, with a tooth on each side towards the apex, and naked at the base; and the tongue is lacerated.

1. The excubitor, great cinereous shrike, or greater butcher-bird, is in length 10 inches. The plumage on the upper parts is of a pale ash-colour; the under, white; through the eyes there is a black stripe; the scapulars are white; the base of the greater quills is white, the rest black. The method of killing its prey is singular, and its manner of devouring is not less extraordinary: small birds it will seize by the throat, and strangle; and which probably is the reason the Germans also call this bird wurchangel, or the suffocating angel. It feeds on small birds, young nestlings, beetles, and caterpillars. When it has killed the prey, it fixes them on some thorn, and when thus spitted, pulls them to pieces with its bill. When confined in a cage, they will often treat their food in much the same manner, sticking it against the wires before they devour it. This bird inhabits many parts of Europe and North America. The female makes its nest with heath and moss, lining it with wool and gossamer, and lays six eggs, about as big as those of a thrush, of a dull olive-green, spotted at the thickest end with black. In spring and summer it imitates the voices of other birds, by way of decoying them within reach, that it may destroy them; but beyond this the natural note is the same throughout all seasons. In countries where they are plenty, the husbandmen value them, on supposition of their destroying rats, mice, and other vermin. They are supposed to live five or six years; and are often trained up for catching small birds in Russia.

2. The collurio, or lesser butcher-bird, is seven inches and a half in length. This bird is much more common than the former species. Mr. Latham suspects its being a bird of passage, never having seen it in winter. It lays six white eggs, marked with a rufous brown circle towards the large end. The nest is generally in a hedge or low bush, near which, it is said, no small bird chooses to build; for it not only feeds on insects, but also on the young of other birds in the nest, taking hold of them by the neck, and strangling them, beginning to eat them first at the brain and eyes. It is fonder of grasshoppers and beetles than of other insects, which it eats by morsels, and when satisfied, sticks the remainder on a thorn: when kept in a cage, it does the same against the wires of it, like the former species.

3. The infaustus, or rock shrike, is in length seven inches and three quarters. The bill is about an inch long, and blackish; the head and neck are of a dark ash-colour, marked with small rufous spots; the upper part of the back is a dark brown; the lower much paler, inclining to ash, especially towards the tail; the quills and wing-coverts are dusky, with pale margins; the breast, and under parts of the body, are orange, marked with small spots, some white and others brown. This species is met with in many parts of Europe, from Italy on the one hand, to Russia on the other; and is found in some parts of Germany, the Alpine mountains, those of Tyrol, and such-like places. The manners of this bird seem disputed. It has an agreeable note of its own, approaching to that of the hedge sparrow; and will also learn to imitate that of others. It makes the nest among the holes of the rocks, &c. hiding it with great art; and lays three or four eggs, feeding the young with worms and insects, on which it also feeds itself. It may be taken young from the nest, and brought up as the nightingale.

4. The faustus, or white-wreathed shrike, is about the size of a common thrush. Its bill is pale; the upper parts of the body are grey; the under ferruginous; from the eyes to the hind head there passes a whitish line, composed of numerous white feathers, rendering it truly characteristic; the wings are rounded; the quills brownish, with grey edges, which are crossed with numerous slender brown lines; the tail is rounded, brown, and crossed with numerous bars of darker brown; the legs are pale. This elegant species inhabits China, where it is known by the name of whommaj. It may be observed, among others, in Chinese paper-hangings, where the white line seems to encompass the back part of the head like a wreath.

5. The tyrannus, or tyrant shrike, is about the size of a thrush. Its bill is a blackish brown, beset with bristles at the base; the irides are brown; the upper parts of the plumage grey brown: the under white; the breast inclines to ash-colour; the head is blackish on the upper part; the base of the feathers on that part in the male is orange, but seldom visible except it erects the feathers, when there appears a streak of orange down the middle of the crown. It inhabits Virginia. There is a variety which inhabits St. Domingo and Jamaica. These birds are called titiri, pipiri, or quiquiri, from their cry, which resembles those words. All authors agree in the manners of these birds, which are ferocious to a great degree while the hen is sitting; no bird whatever dare approach their nest; they will attack the first which comes near, without reserve, and usually come off conquerors.

Many species of this genus are found in Cayenne, and other hot countries, as the lanius varius. See Plate LXXVII. Nat. Hist. fig. 240.

LANNIERS, or LANNIARDS, in a ship, are small ropes reeved into the dead-man's eyes of all shrowds, either to slacken them or to set them tawt; the stays of all masts are also set tawt by lanniers.

LANTANA, or INDIAN SAGE, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is indistinctly quadridentated; the stigma broken, and turned back like a hoof; the fruit is a plum with a bilocular kernel. There are 19 species, consisting of shrubby exotics from Africa and America for the greenhouse or stove, growing to the height of a yard or two, and adorned with oblong, oval, and roundish simple leaves, with monopetalous, tubular, four-parted flowers of different colours. They may be propagated either by seeds or cuttings. 1. The camara or wild sage, is remarkable for the beauty of its flowers, which are yellow, tinged with red. 2. The involucrata, or sea-side sage, has small ash-coloured leaves and a most agreeable smell. They are both natives of the West Indies, the former growing wild among the bushes, and the latter being found near the sea. Their leaves, particularly those of the sea-side sage, are used by the black people in teas for colds and complaints of the stomach. 3. The aculeata is a beautiful stove plant, remarkable for its flowers changing from yellow to red. See Plate LXXVII. Nat. Hist. fig. 243.

LANTERN, MAGIC, an optic machine, whereby little painted images are represented so much magnified, as to be accounted the effect of magic by the ignorant. See OPTICS.

LANTERN. See ARCHITECTURE.

LAPIDARY. There are various machines employed in the cutting of precious stones, according to the quality: the diamond, which is extremely hard, is cut on a wheel of soft steel, turned by a mill, with diamond-dust, tempered with olive-oil, which also serves to polish it.

The Oriental ruby, sapphire, and topaz, are cut on a copper wheel with diamond-dust, tempered with olive-oil, and are polished on another copper wheel with tripoli and water. The hyacinth, emerald, amethyst, garnets, agates, and other stones, not of an equal degree of hardness with the other, are cut on a leaden wheel with smalt and water, and polished on a tin wheel with tripoli. The turquois of the old and new rock, girasol, and opal, are cut and polished on a wooden wheel with tripoli also.

LAPIS, in general, is used to denote a stone of any kind. See MINERALOGY.

LAPIS *calcedonius*, a genus of stones consisting of silica, a small quantity of alumina, with about one-tenth of lime, and a slight trace of oxide of iron: hard, lightish, shining within, breaking into fragments with sharp edges; compact, not mouldering in the air; of a more or less perfectly conchoidal texture; never opake, tough, admitting of a high polish, and generally of a common form; not melting before the blowpipe. See Pl. LXXVII. Nat. Hist. fig. 241.

LAPLYSIA, or SEA-HARE, a genus of marine insects belonging to the order of vermes mollusca. See Plate LXXVII. The body is covered with membranes reflected. It has a shield-like membrane on the back, a lateral pore on the right side, the anus on the extremity of the back, with four feelers resembling ears. The figure represents the depilans minor, which grows to two inches and a half in length, and to more than an inch in diameter; its body approaches to an oval figure, and is soft, punctated, of a kind of gelatinous substance, and of a pale lead-colour; from the larger extremity there arise four oblong and thick protuberances: these are the tentacula; two of them stand nearly erect, two are thrown backward. It is not uncommon about the shores, especially off Anglesea. It causes, by its poisonous juice, the hair to fall off the hands of those that touch it; and is so extremely fetid as to create sickness at the stomach. The major, or greater sea-hare, grows to the length of eight inches.

LAPPAGO, a genus of the triandria digynia class and order. There is one species, a grass.

LAPSANA, *nipplewort*, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the calyx caliculated, with all the inferior scales canaliculated or finely channelled. There are five species, which grow commonly as weeds by the sides of ditches. The young leaves of the common kind, called dock-cresses, have the taste of radishes, and are eaten raw at Constantinople as a sallad. In some parts of England the common people boil them as greens, but they have a bitter and disagreeable taste.

LAPSE, the omission of a patron to present to a church, within six months after voidable; by which neglect title is given to the ordinary to collate to such church: and in such case, the patronage devolves from the patron to the bishop, from the bishop to the archbishop, and from the archbishop to the king. A donative does not go in lapse; but the ordinary may compel the patron by ecclesiastical censures to fill up the vacancy. But if the donative has been augmented by the governors of queen Anne's bounty, it will lapse in like manner as presentative livings.

LAPSED LEGACY, is where the legatee dies before the testator; or where a legacy is given upon a future contingency, and the legatee dies before the contingency happens. As if a legacy is given to a person when he attains the age of 21 years, and the legatee dies before that age; in this case the legacy is a lost or lapsed legacy, and shall sink into the residuum of the personal estate. 2 Black. 613.

LARBOARD, among seamen, the left hand side of the ship, when you stand with your face towards the head.

LARCENY, is the felonious and fraudulent taking away of the personal goods of another: which goods, if they are above the value of 12*d*. it is called grand larceny; if of that value or under, it is petit larceny: which two species are distinguished in their punishment, but not otherwise. 4 Black. 229.

The mind only makes the taking of another's goods to be felony, or a bare trespass only; but as the variety of circumstances is so great, and the complications thereof so mingled, it is impossible to prescribe all the circumstances evincing a felonious intent, or the contrary: it must therefore be left to the due and attentive consideration of the judge and jury, wherein the best rule is, in

doubtful matters, rather to incline to acquittal, than conviction. But in general it may be observed, that the ordinary discovery of a felonious intent, is, if the party do it secretly, or being charged with the goods deny it. 1 H. H. 509.

As all felony includes trespass, every indictment must have the words feloniously took, as well as carried away; whence it follows, that if the party being guilty of no trespass in taking the goods, he cannot be guilty of felony in carrying them away. 1 Haw. 89.

With respect to what shall be considered a sufficient carrying away, to constitute the offence of larceny; it seems that any the least removing of the thing taken, from the place where it was before, is sufficient for this purpose, though it be not quite carried off. 1 Haw. 93.

As grand larceny is a felonious and fraudulent taking of the mere personal goods of another above the value of 12*d.* so it is petit larceny, where the thing stolen is but of the value of 12*d.* or under. In the several other particulars above-mentioned, petit larceny agrees with grand larceny. 1 Haw. 95.

In petit larceny there can be no accessaries either before or after. 1 H. H. 530.

Larceny from the person. If larceny from the person be done privily without his knowledge, by picking of pockets or otherwise, it is excluded from the benefit of clergy by 8 Eliz. c. 4. provided the thing stolen be above the value of 12*d.* 2 H. H. 336.

But if done openly and avowedly before his face, it is within the benefit of clergy. 1 Haw. 97.

Larceny from the house. Every person who shall be convicted of the feloniously taking away in the day-time, any money or goods of the value of 5*s.* in any dwelling-house, or out-house thereunto belonging, and used to and with the same, though no person be therein, shall be guilty of felony, without benefit of clergy. 39 Eliz. c. 15.

Receiving stolen goods. Any person who shall buy or receive any stolen goods, knowing them to be stolen; or shall receive, harbour, or conceal any felons or thieves, knowing them to be so; shall be deemed accessary to the felony: and being convicted on the testimony of one witness, shall suffer death as a felon convict; but he shall be entitled to his clergy. 5 Anne c. 31.

Any person convicted of receiving or buying stolen goods, knowing them to be stolen, may be transported for fourteen years. 4 Geo. I. c. 11.

Where the principal felon is found guilty to the value of 10*d.* that is, of petit larceny only, the receiver, knowing the goods to have been stolen, cannot be transported for fourteen years, and ought not to be put upon his trial; for the acts which make receivers of stolen goods knowingly, accessaries to the felony, must be understood to make them accessaries in such cases only, where by law an accessary may be; and there can be no accessary to petit larceny. Fost. 74.

Every person who shall apprehend any one guilty of breaking open houses in a felonious manner, or of privately and feloniously stealing goods, wares, or merchandizes, of the value of 5*s.* in any shop, warehouse, coach-house, or stable, though it is not broken open, and though no person is therein to be put in fear, and shall prosecute him to conviction, shall have a certificate without fee, under the hand of the judge, certifying such conviction, and within what parish or place the felony was committed, and also that such felon was discovered and taken, or discovered or taken, by the person so discovering or apprehending; and if any dispute arise between several persons so discovering or apprehending, the judge shall appoint the certificate into so many shares, to be divided among the persons concerned, as to him shall seem just and reasonable. Leache's Cro. Law, 307. See Burglary.

LARK. See Alauda.

LARKSPUR. See Delphinium.

LARVA, in natural history, a name given by Linnæus to insects in that state, called by other writers *erucæ*, or caterpillar.

LARUS, the *gull*, a genus in the order of anseres, the characters of which are: the bill is straight, cultrated, a little crooked at the point, and without teeth; the inferior mandible is gibbous below the apex: the nostrils are linear, a little broader before, and situated in the middle of the beak. The different species are principally distinguished by their colour. The most remarkable are,

1. The marinus, or black-backed gull, in length 29 inches, in breadth five feet nine. The bill is very strong and thick, and almost four inches long; the colour a pale yellow; the head, neck, whole under-side, tail, and lower part of the back, are white; the upper part of the back and wings are black; the quill-feathers tipt with white; the legs of a pale flesh-colour. It inhabits several parts of England, and breeds on the highest cliffs. The egg is blunt at each end, of a dusky olive-colour, quite black at the greater end, and the rest of it thinly marked with dusky spots. It is also common on most of the northern coasts of Europe. It frequents Greenland, but chiefly inhabits the distant rocks. It lays three eggs in May, placing them on the heaps of dung which the birds leave there from time to time. It is said to attack other birds, and to be particularly an enemy to the eider duck. It very greedily devours carrion, though its most general food is fish. It is common also in America, as low as South Carolina, where it is called the old-wife.

2. The cataractes, or Skua gull, is in length two feet; the extent four feet and a half; the weight three pounds; the feathers on the head, neck, back, scapulars, and coverts of the wings, are of a deep brown, marked with rust-colour (brightest in the male). The breast, belly, and vent are ferruginous, tinged with ash-colour. This bird inhabits Norway, the Ferroe isles, Shetland, and the noted rock Foula a little west of them. It is also a native of the South Sea. It is the most formidable of the gulls; its prey being not only fish, but what is wonderful in a web-footed bird, all the lesser sort of water-fowl, such as teal, &c. Mr. Schroter, a surgeon in the Ferroe isles, relates that it likewise preys on ducks, poultry, and even young lambs. The natives of the Orkneys are often very rudely treated by them while they are attending their sheep on the hills, and are obliged to guard their heads by holding up their sticks, on which the birds often kill themselves. In Foula it is a privileged bird, because it defends the flocks from the eagle, which it beats and pursues with great fury; so that even that rapacious bird seldom ventures near its quarters.

3. The parasiticus, or dung-hunter, is in length 21

inches: the upper parts of the body, wings, and tail, are black; the base of the quills white on the inner webs; and the two middle feathers of the tail are near four inches longer than the rest. This is a northern species, and very common in the Hebrides, where it breeds on heath. It comes in May, and retires in August; and if disturbed flies about like the lapwing, but soon alights. It is also found in the Orkneys; and on the coasts of Yorkshire, where it is called the feaser. This bird does not often swim, and flies generally in a slow manner, except in pursuit of other birds, which it often attacks, in order to make them disgorge the fish or other food which this common plunderer greedily catches up.

4. The canus, or common gull, is in length 16 or 17 inches; in breadth 36; weight one pound. The bill is yellow; the head, neck, under parts of the body and tail are white; the back and wings pale-grey. It is a tame species, and may be seen by hundreds on the shores of the Thames and other rivers, in the winter and spring, at low tides, picking up the various worms and small fish left by the tides; and will often follow the plough in the fields contiguous, for the sake of worms and insects which are turned up; particularly the cockchafer or dorbeetle in its larva state, which it joins with the rooks in devouring most greedily.

5. The tridactylus, or tarrock, is in length 14 inches, breadth 36; weight seven ounces. The head, neck, and under parts, are white; near each ear, and under the throat, there is a black spot; and at the hind part of the neck a crescent of black; the back and scapulars are bluish-grey; the wing-coverts dusky edged with grey, some of the larger wholly grey. This species breeds in Scotland, and inhabits other parts of northern Europe, quite to Iceland and Spitzbergen. It is observed frequently to attend the whales and seals, for the sake of the fish which the last drive before them into the shallows, when these birds dart into the water suddenly, and make them their prey.

6. The ridibundus, peewit, or black-head gull, is in length 15 inches, breadth three feet; weight ten ounces; the back and wings are of an ash-colour; the neck, all the under parts, and tail, are white; the first ten quills are white, margined, and more or less tipped with black; the others of an ash-colour. This species breeds on the shores of some of our rivers; but full as often in the inland fens of Lincolnshire, Cambridgeshire, and other parts of England. They make their nest on the ground, with rushes, dead grass, &c. and lay three eggs of a greenish brown, marked with red-brown blotches. After the breeding season, they again disperse to the sea-coasts. The young birds in the neighbourhood of the Thames are thought good eating, and are called the red legs. They were formerly more esteemed, and numbers were annually taken and fattened for the table. Whitelock, in his annals, mentions a piece of ground near Portsmouth, which produced to the owner 40*l.* a year by the sale of peewits, or this species of gull. These are the seagulls that in old times were admitted to the noblemen's tables. The note of these gulls is like a hoarse laugh.

7. The atricilla, or laughing gull, is in length 18 inches, breadth three feet. It is found in Russia on the river Don, particularly about Tschercask. The note resembles a coarse laugh, whence the name of the bird. It is met with also in different parts of the continent of America, and is very numerous in the Bahama islands.

There are 14 or 15 other species of this genus. See Plate LXXVII. Nat. Hist. fig. 242.

LARYNX. See Anatomy.

LASH, or Lace, in the sea language, signifies to bind and make fast.

LASERPITIUM, *lazar-wort*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The fruit is oblong, with eight membranaceous angles; the petals inflexed, emarginated, and patent. There are 15 species, none of which are at all remarkable for their beauty, so are only preserved in botanic gardens for the sake of variety.

LASIOSTOMA, a genus of the class and order tetrandria monogynia: the calyx is very short, five-petalled; corolla funnel-form, four-cleft; caps. orbiculate, one-celled, two-seeded. There is one species, a shrub of Guiana.

LASKETS, small lines, like loops, sewed to the bonnets and drablers of a ship, to lash or lace the bonnets to the courses, or the drablers to the bonnets.

LASKING, at sea, is much the same with going large, or veering; that is, going with a quarterly wind.

LAST, in general, signifies the burden or load of a ship. It signifies also a certain measure of fish, corn, wool, leather, &c. A last of codfish, white herrings, meal, and ashes for soap, is 12 barrels; of corn or rapeseed 10 quarters; of gunpowder 24 barrels; of red-herrings 20 cades; of hides 12 dozen; of leather 20 dickers; of pitch and tar 14 barrels; of wool 12 sacks; of stockfish 1000; of flax or feathers 1700 pounds.

LATH, in building, a long, thin, and narrow slip of wood, nailed to the rafters of a roof or ceiling, in order to sustain the covering. These are distinguished into three kinds, according to the different kinds of wood of which they are made, viz. heart of oak, sap-laths, and deal-laths; of which the last two are used for ceilings and partitions, and the first for tiling only. Laths are also distinguished according to their length, into five-feet, four-feet, and three-feet laths, though the statute allows but of two lengths, those of five and those of three feet, each of which ought to be an inch and a half in breadth, and half an inch in thickness, but they are commonly less.

LATHE, a very useful engine for turning of wood, ivory, metals, and other materials. The invention of the lathe is very ancient; Diodorus Siculus says, the first who used it was a grandson of Dædalus, named Talus. Pliny ascribes it to Theodore of Samos, and mentions one Thericles, who rendered himself very famous by his dexterity in managing the lathe. With this instrument the ancients turned all kinds of vases, many whereof they enriched with figures and ornaments in basso relievo. Thus Virgil: "Lenta quibus torno facili superaddita vitis." The Greek and Latin authors make frequent mention of the lathe; and Cicero calls the workmen who uses it vascularii. It was a proverb among the ancients, to say a thing was formed in the lathe, to express its delicacy and justness.

The lathe is composed of two wooden cheeks or sides, parallel to the horizon, having a groove or opening between; perpendicular to these are two other pieces called

puppets, made to slide between the cheeks, and to be fixed down at any point at pleasure. These have two points, between which the piece to be turned is sustained; the piece is turned round, backwards and forwards, by means of a string put round it, and fastened above to the end of a pliable pole, and underneath to a treadle or board moved with the foot. There is also a rest which bears up the tool, and keeps it steady.

The most simple kind of lathe is too well known to require a more ample description. We shall therefore give a figure of an improved lathe manufactured by Mr. Maudslay of Margaret-street. A (Pl. LXXVIII. Misc. fig. 138.) is the great wheel, with four grooves on the rim: it is worked by a crank B and treadle C, in the common way; the catgut which goes round this wheel passes also round a smaller wheel D, called the mandrel, which has four grooves on its circumference of different diameters for giving it different velocities, corresponding with the four grooves on the great wheel A. In order to make the same band suit when applied to all the different grooves on the mandrel D, the wheel A can be elevated or depressed by a screw *a*, and another at the other end of the axle; and the connecting rod C can be lengthened or shortened by screwing the hooks at each end of it further out of, or into it. The end M, fig. 139. of the spindle of the mandrel D, is pointed, and works in a hole in the end of a screw, put through the standard E, fig. 138.; the other end of the bearing F, fig. 139. is conical, and works in a conical socket in the standard, so that by tightening up the screw in E, the conical end F may at any time be made to fit its socket: the puppet G has a cylindric hole through its top to receive the polished pointed rod *d*, which is moved by the screw *e*, and fixed by the screw *f*; the whole puppet is fixed on the triangular prismatic bar H, by a clamp fig. 143, the two ends of which, *a*, *b*, are put through holes *b*, in the bottom of the puppet under the bar, and the whole is fixed by the screw *c* pressing against it; by this means the puppet can be taken off the bar without first taking off the standard I, as in the common lathes; and the triangular bar is found to be far preferable to the double rectangular one in common use. The rest J is a similar contrivance; it is in 3 pieces; see figs. 140. 141, 142. Fig. 141 is a piece, the opening (*a*. *b*, *c*) in which is laid upon the bar H, fig. 138.; the four legs *d d d d* of fig. 142. are then put up under the bar (into the recesses in fig. 141. which are made to receive them), so that the notches in *d d d d* may be level with the top of fig. 141.: the two beads *e f* in fig. 140. are then slid into the notches in the top of *d d d d*, to keep the whole together; the groove *i* is to receive a corresponding piece on *e f*, fig. 140., to steady it; the whole of fig. 140. has a metallic cover, to keep the chips out of the grooves. It is plain, that by tightening the screw *h* in the bottom of figs. 138. and 142., the whole will be fixed and prevented from sliding along the bar H, and fig. 140. from sliding in a direction perpendicular to the bar; the piece *l*, on which the tool is laid, can be raised or lowered at pleasure, and fixed by the screw *m*. On the end *n* of the spindle P, figs. 138. and 139., is screwed occasionally an universal chuck for holding any kind of work which is to be turned (fig. 144.). A is the female screw to receive the screw *n*, fig. 138.; Near the bottom of the screw A is another BB, which is prevented from moving endways by a collar in the middle of it fixed to the screw A.: one end of the screw BB is cut right-handed, and the other left-handed, so that by turning the screw one way, the two nuts EF will recede from each other, or by turning it the contrary way, they will advance towards each other; the two nuts EF pass through an opening in the plate C, and project beyond the same, carrying jaws like those of a vice, by which the subject to be turned is held.

The large lathes which Mr. Maudslay uses in his manufactory, instead of being worked by the foot, as represented in fig. 138., are worked by hand; the wheel and fly-wheel which the men turn work by a strap on another wheel, fixed to the ceiling directly over it; on the axis of this wheel is a larger one, which turns another small wheel or pulley, fixed to the ceiling, directly over the mandrel of the lathe; and this last has on its axis a larger one which works the mandrel D, by a band of catgut. These latter wheels are fixed in a frame of cast iron, moveable on a joint; and this frame has always a strong tendency to rise up, in consequence of the action of a heavy weight; the rope from which, after passing over a pulley, is fastened to the frame. This weight not only operates to keep the mandrill-band tight, when applied to any of the grooves therein, but always makes the strap between the two wheels on the ceiling fit. As it is necessary that the workman should be able to stop his lathe, without the men stopping who are turning the great wheel, there are two pulleys, or rollers, (on the axis of the wheel over the lathe) for the strap coming from the other wheel, on the ceiling; one of these pulleys, called the dead pulley, is fixed to the axis, and turns with it; and the other which slips round it, is called the live pulley: these pulleys are put close to each other, so that by slipping the strap upon the live pulley, it will not turn the axis; but if it is slipped on the other, it will turn with it: this is effected by an horizontal bar, with two upright pins in it, between which the strap passes. This bar is moved in such a direction as will throw the strap upon the live pulley, by means of a strong bell-spring; and in a contrary direction it is moved by a cord fastened to it, which passes over a pulley, and hangs down within reach of the workman's hand: to this cord is fastened a weight, heavy enough to counteract the bell-spring, and bring the strap up to the dead pulley, to turn the lathe; but when the weight is laid upon a little shelf, prepared for the purpose, the spring will act and stop it.

The following is a description of Mr. Smart's newly invented lathe for turning cylinders of wood for the purpose of tent-poles, pickets, handles for tools, &c. &c. the operations of which are so readily performed, that from octagonal bars of yellow deal, $5\frac{1}{2}$ feet long (previously prepared by means of a circular saw) one man, besides two labourers to turn the wheel, will turn out 600 perfectly cylindrical poles, in the space of 12 hours. AA, fig. 6., (Plate Smart's lathe) represents the standards for supporting the great wheel, that gives motion to the lathe; these are supported by pieces of board BB spiked to the ceiling or joists above, and by others CC fixed to the floor of the workshop. The great wheel DD is grooved round the edge for receiving the endless screw B and E, and is put in motion by the winch-handle F F. G and

H are the standards of the lathe, firmly fixed to the floor, and carrying the side-pieces or bed I I; the standard G is tall enough to act as a fixed puppet, and has a screw *a* working through it, for supporting the end of the mandrel or spindle of this lathe, as in the common lathe. K, L, and M, are three other puppets that can be fixed in any place desired, by wedges beneath the bed as usual. To the puppet K is screwed a thick iron plate *b*, which has a conical socket, nicely turned and polished, for receiving the mandrel: this puppet is farther steadied by a brace N, screwed to it, and to the floor of the shop. To the puppet K and L two bars *oo* are fixed by screws, and the same are further supported and steadied by three short puppets P P P. The mandrel, and its pulley Q, are nearly of the common construction, except that the end *c* has a steel point in its centre, and two shorter points for preventing the octagonal piece of wood intended to be turned from slipping or turning without the mandrel. The puppet L has a square-pointed bar *d* fitted to it; and the puppet M has a screw, worked by its handle *e*, which by means of a collar advances or draws back the bar *d*. R is a piece of wood, fixed to the bed and to the floor, for the purpose of carrying a pulley *f*, whose use is to prevent the wheel-band EE from wearing by friction at the place where it crosses. Figs. 7. and 8. represent the gouge and plane, successively used instead of the common turner's chisel, &c.: the pieces of board *aa* are screwed to the block *b*, just at the proper distance of the outsides of the bars *oo*, fig. 1., so that when the tools, figs. 7. and 8. are placed on them, they can be slid along steadily, between the puppets K and L.; the holes *cc* being so adapted as to suit the mandrel and bar *c* and *d* as centres, and their diameters are sufficient to let the octagonal bar intended to be turned to pass through them, without touching; *d*, fig. 7., is a piece of tempered steel, formed as a gouge, and screwed fast to the side of the block, in the proper position for roughing off the angles of the octagonal bar, as it advances, and turns through the hole *c*. *c* fig. 7., is a flat piece of steel, like a plane-iron (shown separately at *f*), which is so fixed by a screw, that it may smooth or complete the cylindrical surface of a pole, already gouged as above, which is advanced, and turned through it. The operation is thus performed: The two tools fig. 7 and 8, are placed on the bar *oo*, fig. 6, and shoved close up to the puppet I; the square bar being long enough for its point *d*, then to project through the centres of the holes *cc*, figs. 7 and 8. The workman then takes an octagonal pole, enters the centre pin of the mandrel *c* into the centre of its end, and the point *d* into the centre of the other end, turning the handle *e* sufficiently to allow the pole to be steadily turned: the wheel D is then set in motion; the workman pushes the gouge-tool, fig. 8., forwards, towards the puppet K, which, as it advances quickly, strikes off the angles of the pole in a rough or screw-like form. When the gouge-tool, fig. 8, has advanced to the end of the pole, the finishing-tool, fig. 7., is in like manner shoved forwards by the workman; and as it advances, the pole is turned into a complete and smooth cylinder. The projection of the mandrel *bc*, fig. 6, is sufficient to admit the gouge and plane tools, to advance so as to clear the end of the pole; and by turning back the handle *c*, the same can be taken out of the lathe as soon as it is stopped. The velocity of the mandrel Q is so as to make upwards of 1200 turns per minute.

LATHRÆA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is quadrifid; there is a depressed glandule at the base of the suture of the germen. The capsule is unilocular. There are four species.

LATHS, *cleaving of.* The lath-cleavers having cut their timbers into lengths, cleave each piece with wedges into 8, 12, or 16, according to the size of their timber; these pieces are called bolts: this is done by the felt grain, which is that grain which is seen to run round in rings at the end of a piece of a tree. Thus they are cut out for the breadth of the laths, and this work is called felting. Afterwards they cleave the laths into their proper thickness with their chit, by the quarter-grain, which is that which runs in straight lines towards the pith.

LATHYRUS, *chickling vetepo*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionacea. The stylus is plain, villous above, towards the end broader; the upper two segments of the calyx are shorter than the rest.

The species are 23, among which are: 1. The latifolius, or everlasting pea. 2. The odorata, or sweet-scented pea. 3. The tangitenus, or Tangier-pea, also an annual, and well known.

LATITAT, a writ whereby all men in personal actions are called originally to the king's bench. F. N. B. 78.

A latitat may be considered either as the commencement of the action, or only as a process to bring the defendant into court, at the election of the plaintiff. Bul. N. P. 151.

If it is stated as the commencement of the action to avoid a tender, the defendant may deny that the plaintiff had any cause of action at the time of suing it out. 1 Wils. 141.

Or if it is replied to a plea of the statute of limitations, the defendant, in order to maintain his plea, may aver the real time of suing it out, in opposition to the test. 2 Burr. 950. See Impey's B. R. and C. B. Practice.

LATITUDE. See GEOGRAPHY.

LATITUDE. See ASTRONOMY.

LATTEN denotes iron plates tinned over, of which tea-canisters are made.

LATTEN-BRASS, plates of milled brass, reduced to different thickness, according to the uses it is intended for.

LATUS RECTUM, in conic sections, the same with parameter. See CONIC SECTIONS.

LATUS TRANSVERSUM, in the hyperbola, that part of the transverse diameter, intercepted between the vertices of the two opposite sections.

LAVANDULA, *lavender:* a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillatæ. The calyx is ovate, and little dentated, supported by a bractea or floral leaf; the corolla is resupinated; the stamina within the tube.

The species are seven in number, among which are: 1. The spica, or spike lavender, has a short shrubby stalk. The varieties of this are: common narrow-leaved laven-

der, with blue flowers, and with white flowers; broad-leaved lavender; dwarf lavender: all of them flowering in July. This species is the common lavender; but the narrow-leaved variety, with blue flowers, is the sort commonly cultivated for its flowers for medicine. 2. The stœchas, or French lavender, has a shrubby very branchy stalk, rising two or three feet high; very narrow, spear-shaped, pointed, hoary leaves, opposite; and all the branches terminated by short bushy spikes of purple flowers in June and July, succeeded by seeds in August. There is a variety with white flowers. 3. The dentata, or dentate-leaved stœchas, has a woody stalk, branching on every side three or four feet high; leaves deeply indented in a pinnated manner; and the branches terminated by scaly four-cornered spikes of flowers, appearing most part of summer.

The first two species are proper for the kitchen-garden, and for medicinal and other family uses, and to plant in the pleasure-ground to adorn the front of small shrubbery compartments, where they will increase the variety very agreeably; and are finely scented aromatics, both when growing, and their flowers when gathered; especially those of the first species, which are in great esteem for putting among clothes, and for distilling, and other economical uses. The flowers of the first sort are gathered for use in July.

LAVATERA, a genus of the polyandria order, in the polydelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The exterior calyx is double and trifid; the arilli or seed-coats are very many and monospermous. There are 9 species, most of them herbaceous flowery annuals, or shrubby perennials, growing erect from two or three to eight or ten feet high. They are easily propagated by seed in the open ground in the spring, and thrive best when sown where they are designed to remain.

LAUDANUM. See Pharmacy.

LAUGERIA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking among those of which the order is doubtful. The corolla is quinquefid; the fruit is a plum with a quinquelocular kernel. There are two species, shrubs of the West Indies.

LAUNCH, in the sea-language, signifies to put out: as, launch the ship, that is, put her out of the dock; launch aft, or forward, speaking of things that are stowed in the hold, is, put them more forward; launch, ho! is a term used when a yard is hoisted high enough, and signifies hoist no more.

LAUNDER, among miners, a place where they wash the powdered ore.

LAUREATION, in the universities of Scotland, signifies the act of taking the degree of master of arts, which the students are permitted to do after four years study.

LAURUS, *the bay-tree*, a genus of the monogynia order, in the enneandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There is no calyx; the corolla is calycine, or serving in place of the calyx, and sexpartite: the nectarium with three glandules, each terminated by two bristles surrounding the germen. The interior filaments furnished with glandules at the base; the fruit a monospermous plum. There are 32 species, of which the most noted are: 1. The nobilis, or evergreen bay-tree, a native of Italy, and has an upright trunk branching on every side from the bottom upward, with spear-shaped, nervous, stiff, evergreen leaves, three inches long, and two broad; and small, yellowish, quadrifid, diœcious flowers, succeeded by red berries in autumn and winter. Of this species there are varieties, with broad, narrow, striped, or waved leaves. 2. The æstivalis, or deciduous bay, grows naturally in North America. It rises with an upright stem, covered with a purplish bark, having oblong, oval, acuminated, veined, deciduous leaves, two or three inches long, and half as broad, growing opposite, with small white flowers succeeded by red berries. 3. The benzoin, or benjamin tree, is also a native of North America; grows 15 or 20 feet high, divided into a very branchy head, with oval, acute, deciduous leaves, three or four inches long, and half as broad; and small yellowish flowers, not succeeded by berries in England. This, it is to be remarked, is not the tree which bears the gum benzoin, that being a species of hyrax. 4. The sassafras is a native of the same country. It has a shrub-like straight stem, with both oval and three-lobed, shining, deciduous leaves, of different sizes, from three to 6 inches long, and nearly as broad, with small yellowish flowers succeeded by blackish berries, but not in England. 5. The indica, or Indian bay-tree, rises with an upright straight trunk, branching regularly 20 or 30 feet high, adorned with very large, spear-shaped, plane, nervous, evergreen leaves on reddish footstalks; and bunches of small whitish-green flowers, succeeded by large oval black berries, which do not ripen in England. 6. The barbonia, or Carolina red bay-tree, rises with an upright straight stem, branching 15 or 20 feet high; with large, spear-shaped, evergreen leaves, transversely veined; and long bunches of flowers on red footstalks, succeeded by large blue berries sitting in red cups. 7. The camphora, or camphor-tree, grows naturally in the woods of the western parts of Japan, and in the adjacent islands. See Pl. LXXVII. Nat. Hist. fig. 244. The root smells stronger of camphor than any of the other parts, and yields it in greater plenty. The bark of the stalk is outwardly somewhat rough; but in the inner surface smooth and mucous, and therefore easily separated from the wood, which is dry, and of a white colour. The flowers are produced on the tops of footstalks, which proceed from the armpits of the leaves; but not till the tree has attained considerable age and size. The flower-stalks are slender, branched at the top, and divided into very short pedicles, each supporting a single flower. These flowers are white, and consist of six petals, which are succeeded by a purple and shining berry of the size of a pea, and in figure somewhat top-shaped. It is composed of a soft pulpy substance, that is purple, and has the taste of cloves and camphor; and of a nucleus or kernel of the size of a pepper, which is covered with a black, shining, oily corticle, of an insipid taste. 8. The cinnamomum, or cinnamon-tree, is a native of Ceylon. It has a large root, and divides into several branches, covered with a bark, which on the outer side is of a greyish brown, and on the inside has a reddish cast. The wood of the root is hard, white, and has no smell. The body of the tree, which grows to the height of 20 or 30 feet, is covered, as well as its numerous branches, with a bark which at first

is green and afterwards red. The leaf is longer and narrower than the common bay-tree; and it is three-nerved, the nerves vanishing towards the top. When first unfolded, it is of a flame-colour; but after it has been for some time exposed to the air, and grows dry, it changes to a deep green on the upper surface, and to a lighter on the lower. The flowers are small and white, and grow in large bunches at the extremity of the branches: they have an agreeable smell, something like that of the lily of the valley. The fruit is shaped like an acorn, but is not so large. 9. The cassia, or base cinnamon, has lanceolated leaves, triple-nerved. 10. The persea, avocado-pear tree, or alligator pear, rises to a considerable height, with a straight trunk, of which the bark and wood are of a greyish colour. The leaves are long, oval, pointed, of a substance like leather, and of a beautiful green colour. The flowers are produced in large knots or clusters, at the extremities of the branches, and consist each of six petals disposed in the form of a star, and of a dirty-white or yellow colour, with an agreeable odour, which diffuses itself to a considerable distance. It is a native of the West Indies. The persea begins to bear two years and a half, or at most three years, after being planted; and like most of the trees in warm climates, bears twice a year.

LAVENIA, a genus of the class and order syngenesia polygamia æqualis. The calyx is nearly regular; style bifid; down three-awned; recept. naked. There are two species, herbs of the East and West Indies.

LAW. Laws of England are divided into lex non scripta, or the common law; and lex scripta, or statute law.

The lex non scripta is not so called from its being conveyed down from former ages by word of mouth, but because the original authority of these laws is not set down in writing, and they receive their force by long usage, and by their universal reception throughout the kingdom; and it is curious to observe, that these rude maxims of our ancestors, of which no person knows clearly the origin, exceed in clearness, brevity, and authority, all that the united wisdom of the most enlightened men have produced in later ages.

The common law is divided into:

1st. General custom, which is the universal rule of the whole kingdom, and is the law by which proceedings and determinations in the courts of justice are ordinarily directed. This for the most part settles the course of inheritance, the manner and form of acquiring and transferring property, the solemnities and obligations of contracts, the rules of expounding wills, deeds, and acts of parliament; the remedies of civil injuries, the different kinds of offences with the punishments allotted to each; the institution of four superior courts of record; and many other particulars which diffuse themselves as extensively as the distribution of common justice requires, all of which are not enacted by any particular statutes (though they are acknowledged by all) but depend entirely upon the common law.

2dly. Particular customs which concern the inhabitants of some particular district.

3dly. The third branch are those laws which are adopted by certain courts and jurisdictions, as the civil and canon laws.

The civil law is understood to signify the civil law of the Roman empire. The canon law is a body of Roman ecclesiastical law relating to matters over which the church exercises a jurisdiction. The civil law is used in four courts under certain restrictions, viz. the archbishops' and bishops' courts, usually styled curiæ christianitatis; the courts martial, the courts of admirality, and the courts of the two universities.

The second division of the laws of England are the statutes made by the king, lords, and commons, assembled in parliament. The oldest statute extant is the celebrated Magna Charta, 9 Hen. 3; though, doubtless, the records of many antecedent to that have been lost, and the maxims received as common law.

Statutes are general or special, public or private: general or public acts are those which concern the whole nation; of these the judges are obliged to take notice, though they should not be formally pleaded by the party who claims an advantage under them. Special or private acts are such as operate on private persons and concerns, which must be formally set forth by the party, or the judges are not obliged to notice them.

Statutes are either declaratory of the common law, where it is become disreputable, or fallen into disuse; or remedial, when made to supply the defects, or abridge the superfluities of the common law. These latter are subdivided into enlarging and restraining statutes, by enlarging the common law where it was too circumscribed, and restraining it where it was too luxuriant.

There is besides those grounds of the laws of England, a court of equity to moderate and explain them. (See Equity.) The courts of equity are, however, only had recourse to in matters of property; for their constitution will not permit, that in criminal cases any judge should have the power of construing the law otherwise than according to the letter. This caution, while it protects the public liberty, can never oppress the individual. A man cannot suffer more punishment than the law directs, but he may suffer less. The laws cannot be strained to inflict a penalty beyond what the letter warrants, but in cases where the letter induces any apparent hardship, the crown has power to pardon.

In treating of the laws, the best mode, and which has been adopted by sir William Blackstone in his excellent Commentaries, after the example of Wood in his Institutes, is to divide them, 1st, into the rights of persons, or the rights as to personal security, personal liberty, and private property. 2nd, The rights of things, or the rights which a man may acquire in and to such external things as are unconnected with his person. 3rd. Private wrongs, or such as are the infringement of the private rights of individuals: and 4th. public wrongs, or such as are a violation of the public rights, and affect the whole community.

It is of course unnecessary, and perhaps in a work of this nature irrelevant, to recommend the study of the law; it is sufficient to add the words of the great judge Blackstone on this subject. "It is incumbent (says he) upon every man to be acquainted with the laws, lest he incur the censure as well as the inconvenience of living in society without knowing the obligations it lays him under."

LAWSONIA, *Egyptian privet*, a genus of the monogynia order, in the octandria class of plants, and in the

natural method ranking with those of which the order is doubtful. The calyx is quadrifid; the petals four; the stamina four, in pairs; the capsule is quadrilocular and polyspermous. There are four species, all natives of India. Some authors take the inermis to be the plant termed by the Arabians henna or alhenna, the pulverised leaves of which are much used by the Eastern nations for dyeing their nails yellow; but others, Dr. Hasselquist in particular, attribute that effect to the leaves of the other species of Egyptian privet which bears prickly branches. It is probable that neither set of writers are mistaken, and that the shrub in question is a variety only of the thorny lawsonia, rendered mild by culture.

LAY-BROTHERS, among the Romanists, those pious, but illiterate persons, who devote themselves, in some convent, to the service of the religions. They wear a different habit from that of the religious, but never enter into the choir, nor are present at the chapters; nor do they make any other vow, except of constancy and obedience. In nunneries there are also lay-sisters.

Lay-man, among painters, a small statue either of wax or wood, whose joints are so formed, that it may be put into any attitude or posture. Its principal use is for adjusting the drapery in clothing of figures.

LAYERS, in gardening, are tender shoots or twigs of trees, laid or buried in the ground, till, having struck root, they are separated from the parent tree, and become distinct plants. The propagating trees by layers is done in the following manner: the branches of the trees are to be slit a little way, and laid under the mould for about half a foot: the ground should be first made very light, and after they are laid they should be gently watered. If they will not remain easily in the position they are put in, they must be pegged down with wooden hooks: the best season for doing this is, for evergreens, toward the end of August, and for other trees in the beginning of Feb. If they are found to have taken root, they are to be cut off from the main plant the succeeding winter, and planted out. If the branch is too high from the ground, a tub of earth is to be raised to a proper height for it. Some pare off the rind, and others twist the branch before they lay it: but this is not necessary. The end of the layer should be about a foot out of the ground; and the branch may be either tied tight round with a wire, or cut upwards from a joint, or cut round for an inch or two at the place, and it is a good method to pierce several holes through it with an awl above the part tied with the wire.

LAZAR-HOUSE, or **Lazaretto**, a public building, in the nature of an hospital, to receive the poor and those afflicted with contagious distempers: in some places lazarettos are appointed for the performance of quarantine; in which case, those are obliged to be confined in them who are suspected to have come from places infected with the plague. This is usually a large building, at some distance from a city, whose apartments stand detached from each other, where vessels are unladen, and the crew shut up for about 40 days, more or less, according to the time and place of their departure. The lazaretto of Milan is esteemed one of the finest hospitals in Italy.

LAZULITE. This stone, which is found chiefly in the northern parts of Asia, was long known to mineralogists by the name of lapis lazuli.

Lazulite is always amorphous. Its texture is earthy. Its fracture uneven. Lustre 0. Opaque, or nearly so. Hardness 8 to 9. Specific gravity 2.76 to 2.945. Colour blue; often spotted white from specks of quartz, and yellow from particles of pyrites.

It retains its colour at 100° Wedgewood; in a higher heat it intumesces, and melts into a yellowish-black mass. With acids it effervesces a little, and if previously calcined, forms with them a jelly.

Margraff published an analysis of lazulite in the Berlin Memoirs for 1758. His analysis has since been confirmed by Klaproth, who found a specimen of it to contain

46.0	silica
14.5	alumina
28.0	carbonat of lime
6.5	sulphat of lime
3.0	oxide of iron
2.0	water
100.0	

From the experiments of Morveau, it appears that the colouring matter of lazulite is sulphuret of iron.

LEAD, one of the perfect metals, appears to have been very early known. It is mentioned several times by Moses. The ancients seem to have considered it as nearly related to tin. It is of a bluish-white colour; and when newly melted is very bright, but it soon becomes tarnished by exposure to the air. It has scarcely any taste, but emits on friction a peculiar smell. It stains paper or the fingers a bluish colour. When taken internally, it acts as a poison. Its hardness is $5\frac{1}{2}$; its specific gravity is 11.3523. Its specific gravity is not increased by hammering, neither does it become harder, as is the case with the other metals; a proof that the hardness which metals assume under the hammer is in consequence of an increase of density. It is very malleable, and may be reduced to very thin plates by the hammer; it may be also drawn out into wire, but its ductility is not great. Its tenacity is such, that a lead wire only $\frac{1}{120}$ inch diameter is capable of supporting 18 pounds without breaking. It melts, according to sir Isaac Newton, when heated to the temperature of 540° Fahrenheit: but Morveau makes its fusing point as high as 594°. When a very strong heat is applied, the metal boils and evaporates. If it is cooled slowly, it crystallizes. The abbe Mongez obtained it in quadrangular pyramids, lying on one of their sides. Each pyramid was composed apparently of three layers. Pajot obtained it in the form of a polyhedron with 32 sides, formed by the concourse of six quadrangular pyramids.

When exposed to the air, it soon loses its lustre, and acquires first a dirty-grey colour, and at last its surface becomes almost white. This is owing to its gradual combination with oxygen, and conversion into an oxide; but this conversion is exceedingly slow; the external crust of oxide, which forms first, preserving the rest of the metal for a long time from the action of the air.

Water has no direct action upon lead; but it facilitates the action of the external air. For when lead is exposed to the air, and kept constantly wet, it is oxidated much more rapidly than it otherwise would be. Hence the rea-

son of the white crust which appears upon the sides of the leaden vessels containing water, just at the place where the upper surface of the water usually terminates.

No less than four different combinations of lead with oxygen are at present known, though some of them have not been examined with much attention.

1. The protoxide, or first oxide of lead, may be obtained by dissolving lead in nitric acid, and boiling the crystals which that solution yields by concentration along with pieces of metallic lead. The consequence is the formation of scaly crystals of a yellow colour, brilliant, and very soluble in water. These crystals are composed of the protoxide of lead combined with nitric acid. The protoxide may be precipitated by means of potass. Its properties have not hitherto been examined. It contains but a small proportion of oxygen.

2. The deutoxide of lead may be formed by dissolving the metal in nitric acid, and pouring potass into the solution. A yellow-coloured powder is obtained, which is the deutoxide of lead. This oxide is composed of 91 parts of lead, and 9 of oxygen. When lead is kept melted in an open vessel, its surface is soon covered with a grey-coloured pellicle. When this pellicle is removed, another succeeds it; and by continuing the heat, the whole of the lead may soon be converted into this substance. If these pellicles are heated and agitated for a short time in an open vessel, they assume the form of a greenish-grey powder. Mr. Proust has shown that this powder is a mixture of deutoxide, and a portion of lead in the metallic state. It owes its green colour to the blue and yellow powders which are mixed in it. If we continue to expose this powder to heat for some time longer in an open vessel, it absorbs more oxygen, assumes a yellow colour, and is then known in commerce by the name of massicot. The reason of this change is obvious. The metallic portion of the powder gradually absorbs oxygen, and the whole of course is converted into deutoxide.

When thin plates of lead are exposed to the vapour of warm vinegar, they are gradually corroded, and converted into a heavy white powder, used as a paint, and called white lead. This powder used formerly to be considered as a peculiar oxide of lead; but it is now known that it is a compound of the deutoxide and carbonic acid.

3. If massicot ground to a fine powder is put into a furnace, and constantly stirred while the flame of the burning coals plays against its surface, it is in about 48 hours converted into a beautiful red powder, known by the name of minium, or red lead. This powder, which is likewise used as a paint, and for various other purposes, is the tritoxide or red oxide of lead.

4. If nitric acid, of the specific gravity 1.260, is poured upon the red-coloured oxide of lead, 185 parts of the oxide are dissolved; but 15 parts remain in the state of a black, or rather deep-brown, powder. This is the peroxide, or brown oxide of lead, first discovered by Scheele. The best method of preparing it is the following, which was pointed out by Proust, and afterwards still farther improved by Vauquelin. Put a quantity of red oxide of lead into a vessel partly filled with water, and make oxymuriatic acid gas pass into it. The oxide becomes deeper and deeper coloured, and is at last dissolved. Pour potass into the solution, and the brown oxide of lead precipitates. By this process 68 parts of brown oxide may be obtained for every 100 of red oxide employed. This oxide is composed of about 79 parts of lead and 21 of oxygen. It is of a brilliant flea-brown colour. When heated it emits oxygen gas, becomes yellow, and melts into a kind of glass. When rubbed along with sulphur in a mortar, it sets the sulphur on fire, and causes it to burn with a brilliant flame. When heated on burning coals the lead is reduced. All the oxides of lead are very easily converted into glass; and in that state they oxidize and combine with almost all the other metals except gold, platinum, and silver. This property renders lead exceedingly useful in separating gold and silver from the baser metals with which they happen to be contaminated. The gold or silver to be purified is melted along with lead, and kept for some time in that state in a flat cup, called a cupel, made of burnt bones, or the ashes of wood. The lead is gradually vitrified, and sinks into the cupel, carrying along with it all the metals which were mixed with the silver and gold, and leaving these metals on the cupel in a state of purity. This process is called cupellation. The lead employed is afterwards extracted from the cupels, and is known in commerce by the name of litharge. It is a half-vitrified substance, of a high red colour, and composed of scales. It is merely an oxide of lead more or less contaminated with the oxides of other metals. But the best litharge is made by oxidizing lead directly, and then increasing the heat till the oxide is fused. The more violent the fusing heat, the whiter is the litharge.

Lead has not yet been combined with carbon, nor hydrogen; but it combines readily with sulphur and phosphorus.

1. Sulphuret of lead may be formed either by stratifying its two component parts, and melting them in a crucible, or by dropping sulphur at intervals on melted lead. The sulphuret of lead is brittle, brilliant, of a deep blue-grey colour, and much less fusible than lead. These two substances are often found naturally combined; the compound is then called galena, and is usually crystallized in cubes. Sulphuret of lead is composed, according to the experiment of Wenzel, of 86.8 parts of lead and 13.2 of sulphur.

2. Phosphuret of lead may be formed by mixing together equal parts of filings of lead and phosphoric glass, and then fusing them in a crucible. It may be cut with a knife, but separates into plates when hammered. It is of a silver-white colour with a shade of blue, but it soon tarnishes when exposed to the air. This phosphuret may also be formed by dropping phosphorus into melted lead. It is composed of about 12 parts of phosphorus, and 88 of lead.

Lead does not combine with azotic gas. Muriatic acid gradually corrodes it, and converts it into a white-coloured oxide.

Lead is capable of combining with most of the metals.

1. Lead may be easily alloyed with gold by fusion. The colour of the gold is injured, and its ductility diminished. This alloy is of no use; but it is often formed in order to purify gold by cupellation.

2. Platinum and lead unite in a strong heat: the alloy is brittle, of a purplish colour, and soon changes on ex-

posure to the air. Many experiments have been made with this alloy, in order, if possible, to purify platinum from other metals by cupellation, as is done successfully with silver and gold: but scarcely any of the experiments have succeeded; because platinum requires a much more violent heat to keep it in fusion than can be easily given.

3. Silver is often alloyed with lead in order to purify it by cupellation. This alloy is very fusible, much softer than silver, and has much less tenacity, elasticity, and sonorousness; its colour is nearly that of lead, and its specific gravity greater than the mean density of the metals alloyed.

4. Mercury amalgamates readily with lead in any proportion, either by triturating it with lead filings, or by pouring it upon melted lead. The amalgam is white and brilliant, and when the quantity of lead is sufficient, assumes a solid form. It is capable of crystallizing. The crystals are composed of one part of lead and one and a half of mercury.

5. Copper and lead may be easily combined by fusion. When the lead exceeds, the alloy is of a grey colour, and ductile while cold, but brittle when hot. It is employed sometimes for the purpose of making printer's types for very large characters.

6. It was formerly supposed that lead does not combine with iron; but the experiments of Guyton Morveau have proved, that when the two metals are melted together, two distinct alloys are formed. At the bottom is found a button of lead containing a little iron; above is the iron combined with a small portion of lead.

7. Lead and tin may be combined in any proportion by fusion. This alloy is harder, and possesses much more tenacity, than tin. Muschenbroeck informs us that these qualities are a maximum when the alloy is composed of three parts of tin and one of lead. What is called in this country ley pewter is often scarcely any thing else than this alloy. Tin foil too almost always is a compound of tin and lead. This alloy, in the proportion of two parts of lead and one of tin, is more soluble than either of the metals separately. It is accordingly used by plumbers as a solder.

The affinities of lead and of its oxide are as follow:

Lead.	Oxide of Lead.
Gold,	Sulphuric acid,
Silver,	Saciactic,
Copper,	Oxalic,
Mercury,	Arsenic,
Bismuth,	Tartaric,
Tin,	Muriatic,
Antimony,	Phosphoric,
Platinum,	Sulphurous,
Arsenic,	Suberic,
Zinc,	Nitric,
Nickel,	Fluoric,
Iron,	Citric,
Sulphur.	Lactic,
	Acetic,
	Boracic,
	Prussic,
	Carbonic.

Lead, *ores o*. Ores of lead occur in great abundance in almost every part of the world. They are generally in veins; sometimes in siliceous rocks, sometimes in calcareous rocks.

The following table exhibits a view of the different states in which this mineral has hitherto been observed.

I. Sulphurets.	III. Salts.
1. Galena,	1. Carbonat,
2. Blue lead ore,	2. Muriocarbonat,
3. Black ore of lead.	3. Sulphat,
	4. Phosphat,
II. Oxides	5. Molybdat,
1. Earthy ore of lead,	6. Arseniat?
2. Arseniated protoxide,	7. Arseniophosphat?
3. Arseniated peroxide.	8. Chromat.

Of these the first species is by far the most common. From it indeed almost the whole of the lead of commerce is extracted.

LEAF. See Botany.

Leaf-gold. See Aurum, Gold, Gilding, &c.

Leaf. See Architecture.

Leaf, in clocks and watches, an appellation given to the notches of their pinions. See Clockwork.

LEAGUE, a measure of length, containing more or less geometrical paces, according to the different usages and customs of countries. A league at sea, where it is chiefly used by us, being a land-measure mostly peculiar to the French and Germans, contains three thousand geometrical paces, or three English miles. The French league sometimes contains the same measure, and in some parts of France it consists of three thousand five hundred paces: the mean or common league consists of two thousand four hundred paces, and the little league of two thousand. The Spanish leagues are larger than the French, seventeen Spanish leagues making a degree, or twenty French leagues, or sixty-nine and a half English statute miles. The Dutch and German leagues contain each four geographical miles. The Persian leagues are pretty near of the same extent with the Spanish: that is, they are equal to four Italian miles, which is pretty near to what Herodotus calls the length of the Persian parasang, which contained thirty stadia, eight of which, according to Strabo, make a mile.

LEAK, among seamen, is a hole in the ship through which the water comes in. To spring a leak is said of a ship that begins to leak; to stop a leak, is to fill it with a plug wrapt in oakum and well tarred; or putting in a tarpaulin clout, to keep the water out; or nailing a piece of sheet-lead upon the place.

LEAKAGE, the state of a vessel that leaks, or lets water, or other liquid, ooze in or out. See the preceding article. Leakage, in commerce, is an allowance of 12 per cent. in the customs, allowed to importers of wines for the waste and damage it is supposed to have received in the passage; an allowance of two barrels in twenty-two is also made to the brewers of ale and beer, by the excise-office.

LEAP, in music. This word is properly applicable to any disjunct degree, but is generally used to signify a distance consisting of several intermediate intervals.

Leap-year. See Bissextile.

LEASE, a conveyance of lands, generally in consideration of rent or other annual recompence made for life,

for years, or at will, but always for a shorter term than the lessor has in the premises, otherwise it partakes more of the nature of an assignment.

By the common law, all persons seized of an estate might grant leases for any period less than their interest lasted; but statutes have been since made, some to enlarge and some to restrict it. They are divided into enabling and restricting statutes; by the enabling stat. 32 Henry VIII. c. 28. a tenant in tail may make leases to ensure for twenty-one years or three lives to bind his issue in tail, but not those in remainder or reversion. Husbands seized in right of their wives may make leases for the same period, provided the wife join in it. All persons seized of an estate of fee-simple in right of their churches, except parsons or vicars, may bind their successors under certain restrictions. 1. The lease must be by indenture; 2. It must begin from the day of making; 3. All old leases must be surrendered or be within a year of expiring; 4. It must be for three lives or twenty-one years, not both; 5. It may be for a shorter term, but must not exceed twenty-one years; 6. It must be of lands and tenements most commonly left for twenty years past; 7. The most usual rent for that time must be reserved; 8. Such leases cannot be made without impeachment of waste. It was also specified that the lease must be of corporal hereditaments, that the lessor might resort to them to distrain; but by stat. 5 Geo. III. c. 17, a lease of tithes or other incorporeal hereditaments may be granted, and the successor shall have his remedy by an action of debt.

From the disabling statutes, we find that all colleges, cathedrals, and other ecclesiastical or eleemosynary corporations, and all parsons and vicars, are restrained from making leases unless under the following regulations: 1. They must not exceed 3 lives or 21 years: 2. The accustomed rent must at least be reserved thereon: 3. Houses in corporations or market-towns may be let for 40 years, provided they are not the mansion-houses of the lessors, or have not more than 10 acres of ground belonging to them and provided the lessee agrees to keep them in repair, and they may be aliened in fee-simple for lands of equal value in recompense: 4. If there is an old lease which has more than 3 years to run, no new lease shall be made: 5. No lease shall be made without impeachment of waste: 6. All bounds and covenants tending to frustrate the provisions of the statutes of 13 and 18 Eliz. shall be void.

Two observations seem to present themselves concerning these statutes: 1. That they do not enable any persons to make such leases as they are by common law restrained from making; therefore, a parson or vicar, though he is restrained from making longer leases than for 21 years or 3 lives, even with the consent of the patron or ordinary, yet is not enabled to make any lease at all, to bind his successor without such consent. 2. Though leases contrary to these acts are void, yet they are good against the lessor during his life, if he is a sole corporation; and if it is an aggregate corporation, as long as the head lives: for the act was intended for the benefit of the successor alone, and it is a maxim of law that no man shall take advantage of his own wrong. With regard to college leases, one-third of the old rent must be reserved in wheat or malt, reserving a quarter of wheat for every 6s. 8d. and a quarter of malt for every 5s.; or the lessees must pay for the same, at the price of the market nearest the respective colleges on the market-day before the rent is due.

There are further restraining statutes which direct that if any beneficial clergyman is absent from his benefice above 80 days in the year, all leases and agreements made by him of the profits of his cure shall be void, except in the case of licensed pluralists; who are allowed to demise the living to the curate, if he is not absent more than 40 days in the year. See 13 Eliz. c. 20. 14 Eliz. c. 11, 18 Eliz. c. 11, and 43 Eliz. c. 9.

All leases except such as do not exceed 3 years from the making, whereupon the reserved rent must be at least two thirds of the improved value, must be in writing, though no particular form of words is necessary to constitute a good lease.

They must be made to natural-born subjects of this realm, or such as have been naturalized, or to denizens, for all leases made to aliens shall be void; and there is even a statute in force, 32 Hen. VIII. c. 16, which imposes a penalty of 5*l*. on the lessor and lessee. It has however been held that an alien merchant may take a house for his own residence, but it shall not go to his executors; the reasons for these laws are evidently to prevent foreigners getting too firm a footing in the kingdom.

Lease and *release* is a conveyance which since the stat. 27 Hen. VIII. c. 10, commonly called the statute of uses, has taken place of the deed of feoffment, as it supplies the need of livery and seisin. It is made thus: A lease or bargain and sale for one year, from the tenant to the lessee, is first prepared, whereby the lessee becomes actually possessed of the lands, then by the above mentioned statute the lessee is enabled to take a grant of the lands intended to be conveyed to him and his heirs for ever; accordingly a release is made, reciting the lease and declaring the uses. In the lease, a pepper-corn is a good consideration to make the lessee capable of receiving a release. This mode of conveyance is become so usual, that it merits peculiar attention. See this matter very ably discussed by the annotator of the latter part of Coke's Commentaries, p. 271, No. 1.

LEASES, *value of.* The purchaser of a lease may be considered as the purchaser of an annuity equal to the rack-rent of the estate; and the same principles, from which are deduced the present value of annuities to continue during any given term, will apply to the value of leases. The sum paid down for the grant of a lease is so much money paid in advance for the annual rents, as they may become due; or, it may be considered as a sum which put out to interest, will enable the lessor to repay himself the rack-rent of the estate, or the yearly value of his interest therein, during the given term; therefore no more money should be demanded by the lessor, for the grant of the lease, than will enable him to do this at a given rate of interest. In order to find what this sum should be it would be necessary to ascertain separately the present value of each annual rent, or the sum which, put out to interest at the given rate, will enable the landlord to repay himself the several yearly rents as they become due. Thus, if a person has 100*l*. due to him a twelvemonth hence, and he wishes to have the value of

LEDUM, marsh cistus, or wild rosemary; a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 18th order, bicornes. The calyx is quinquefid; the corolla plain and quinquepartite; the capsule quinquelocular, and opening at the base. There are three species: The palustre with very narrow leaves, grows naturally upon bogs and mosses in many parts of Yorkshire, Cheshire, and Lancashire. The flowers are produced in small clusters at the end of the branches, and are shaped like those of the strawberry-tree, but spread open wider at top. These are of a reddish colour, and in the natural places of their growth are succeeded by seed-vessels filled with small seeds which ripen in autumn.

LEE, in the sea-language, a word of various significations, though it is generally understood to mean the part opposite to the wind. Thus lee-shore, is that shore against which the wind blows. Lee-latch, or have a care of the lee-latch, is, take care that the ship don't go to the leeward, or too near the shore; a lee the helm, put it to the leeward side of the ship: to lie by the lee, or to come up to the lee, is to bring the ship so, that all her sails may lie flat against her masts and shrouds, and that the wind may come right upon her broadside.

Lee-fang, is a rope reeved into the cringles of the courses, to hale in the bottom of the sail, that the bonnets may be laced on, or the sail taken in.

Lee-way, is the angle that the rhumb-line upon which the ship endeavours to sail, makes with the rhumb upon which she really sails. See Navigation.

LEEA, a genus of the class and order pentandria monogynia. The calyx is one-petalled; necs. on the side of the corolla, upright, five-cleft; berry, five-seed. There are three species, trees of the East Indies.

LEECH. See Hirudo.

LEEK. See Allium.

LEERSIA, a genus of the class and order triandria digynia. Calyx none; glume, two-valved, closed. There are three species, grasses of America.

LEET, a little court held within a manor, and called the king's court, on account that its authority to punish offences originally belonged to the crown, whence it is derived to inferior persons. See Court.

LEETCH-lines, small ropes made fast to the leetch of the topsails, to which they belong, and reeved into a block at the yard close by the topsail-ties. They serve to hale in the leetch of the sail when the topsails are to be taken in.

LEGACY, a bequest of a sum of money, or any personal effects of a testator; and these are to be paid by his representative, after all the debts of the deceased are discharged, as far as the assets will extend.

All the goods and chattels of the deceased, are by law vested in the representative, who is bound to see whether there be left a sufficient fund to pay the debts of the testator, and if it should prove inadequate, the pecuniary legacies must proportionately abate; a specific legacy, however, is not to abate unless there be insufficient without it.

If the legatee die before the testator, such will in general be termed a lapsed legacy, and fall into the general fund; where however, from the general import of the will, it can be collected that the testator intended such a vested legacy, it will in such case go to the representative of the deceased legatee.

If a bequest be made to a person, if or when he attains a certain age, the legacy will be lapsed, if he die before he attain that age; but if such legacy may be made payable at that age, and the legatee die before that age, such legacy will be vested in his representative.

If in the latter case, the testator devise interest to be paid in the mean time, it will nevertheless be a vested legacy.

Where a legacy is bequeathed over to another, in case the first legatee die under a certain age, or the like, the legacy will be payable immediately on the death of the first legatee; and though such legacy be not bequeathed over, yet if it carry interest, the representative will become immediately entitled to it.

In case of a vested legacy due immediately, and charged on land, or money in the funds which yields an immediate profit, interest shall be payable from the death of the testator; but if it be charged on the personal estate only of the testator, which cannot be collected in, it will carry interest only from the end of the year after the death of the testator.

If a bequest be for necessaries, and of small amount, the executor will be justified in advancing a part of the principal; but this should be done under very particular circumspection, as the executor may be compelled to pay the full legacy on the infant's attaining his majority, without deducting the sum previously advanced.

When all the debts and particular legacies are discharged, the residue or surplus must be paid to the residuary legatee, if any be so appointed in the will; but if there be none appointed or intended, it will go to the executor or next of kin.

When the residue does not go to the executor, it is to be distributed among the intestate's next of kin, according to the statutes of distributions; except the same is otherwise disposable by particular customs, as those of London, York, &c. See Executor.

LEGATE, a cardinal or bishop, whom the pope sends as his ambassador to sovereign princes.

There are three kinds of legates, viz. legates a latere, legates de latere, and legates by office, or legati nati; of these the most considerable are the legates a latere, the next are the legates de latere.

Legates by office are those who have not any particular legation given them, but who by virtue of their dignity and rank in the church, become legates; such are the archbishops of Rheims and Arles; but the authority of these legates is much inferior to that of the legates a latere.

LEGATUS, in Roman antiquity, a military officer who commanded as deputy of the chief general.

LEGER-line, in music, one added to the staff of five lines, when the ascending or descending notes run very high or low.

LEGION, in Roman antiquity, a body of foot which consisted of ten cohorts.

The exact number contained in a legion, was fixed by Romulus at three thousand; though Plutarch assures us, that after the reception of the Sabines into Rome, he increased it to six thousand. The common number afterwards, in the first times of the free state, was four thou-

sand; but in the war with Hannibal, it arose to five thousand, and after this it is probable that it sunk again to four thousand, or four thousand two hundred, which was the number in the time of Polybius.

LEGNOTIS, a genus of the class and order polyandria monogynia. The calyx is five-cleft; pet. 5; caps. 3-celled. There are two species, trees of Jamaica and Guiana.

LEMMA, in mathematics, a proposition which serves previously to prepare the way for the more easy apprehension of the demonstration of some theorem, or construction of some problem.

LEMNA, a genus of the monœcia diandria class and order. The male cal. is one-leaved; cor. none; female, cal. one-leaved; cor. none; style one; caps. one-celled. There are six species, known by the name of duck-weed, or duck-meat.

LEMNISEA, a genus of the class and order polyandria monogynia. The cal. is 5-toothed; cor. 6-petalled, recurved; nect. cap-shaped, girding; the germ. per. 5-celled, seeds solitary. There is 1 species, a tree of Guiana.

LEMON. See CITRUS.

LEMON, *salt of.* See OXALAT *of potass.*

LEMUR, MACAUCO, a genus of quadrupeds of the order primates: the generic character is, front-teeth in the upper jaw, four; the intermediate ones remote: in the lower jaw, six; longer, stretched forwards, compressed, parallel, approximated. Canine-teeth solitary, approximated; grinders several, sublobated; the foremost somewhat longer and sharper.

The genus lemur or macauco consists of animals approaching to monkeys in the form of their feet, which, in most species, are furnished with flat nails; but differing in their manners, and void of that mischievous and petulant disposition which so much distinguishes the monkey tribe from other quadrupeds.

In this, as in the former genus, we meet with some species without a tail, while others have that part extremely long. Of the tailless species the most remarkable is the

1. Lemur tardigradus, slow lemur. It is about the size of a small cat, measuring sixteen inches in length; its colour is an elegant pale-brown or mouse-colour; the face flattish; the nose inclining to a sharpened form; the eyes yellow-brown, large, and extremely protuberant, so as to appear in the living animal like perfect hemispheres. They are surrounded by a circle of dark brown, which also runs down the back of the animal. This species is very slow in its motions, and from this circumstance has actually been ranked by some naturalists among the sloths; though in no other respect resembling them. It is a nocturnal animal, and sleeps, or at least lies motionless, during the greatest part of the day; its voice is shrill and plaintive.

2. Lemur indri. This is a very large species; it is entirely of a black colour, except on the face, which is greyish; a greyish cast also prevails towards the lower part of the abdomen, and the rump is white. The face is of a lengthened or dog-like form; the ears shortish and slightly tufted; the hair or fur is silky and thick, and in some parts of a curly or crisped appearance: it is the largest animal of this genus, and is said by Mons. Sonnerat, its first describer, to be three feet and a half high; it is said to be a gentle and docile animal, and to be trained, when taken young, for chace, in the manner of a dog. Its voice resembles the crying of an infant. It is a native of Madagascar, where it is known by the name of Indri, which is said to signify the man of the wood. The nails in this species are flat, but pointed at the ends; and there is no appearance of a tail.

3. Lemur macaco, ruffed lemur. This is the species described by the count de Buffon, under the name of the vari, its colours often consisting of a patched distribution of black and white; though its real or natural colour is supposed to be entirely black. In size it exceeds the mongos, or brown lemur. It is said to be a fierce and almost untameable animal: it inhabits the woods of Madagascar and some of the Indian islands; and is said to exert a voice so loud and powerful as to strike astonishment into those who hear it, resembling, in this respect, the howling monkey or S. Belzebub, which fills the woods of Brazil and Guiana with its dreadful cries. When in a state of captivity, however, it seems to become as gentle as some others of this genus.

The astonishing strength of voice in this animal, depends, according to the count de Buffon, on the peculiar structure of the larynx, which widens, immediately after its divarication, into a large cavity before entering the lungs.

4. Lemur tarsier. This animal is distinguished by the great length of its hind legs. Its general length from the nose to the tail is almost six inches; and from the nose to the hind toes eleven inches and a half; the tail nine inches and a half. The face is sharp or pointed; the eyes very large and full; the ears upright, broad, naked, and rounded. Between the ears on the top of the head is a tuft of long hairs. The colour of this species is grey-brown or mouse-colour, paler beneath. It is a native of Amboina and some other East India islands.

5. Lemur psilodactylus, long-fingered lemur. This highly singular species has so much the general appearance of a squirrel, that it has been referred to that genus both by Mr. Pennant in the last edition of his History of Quadrupeds, and by Gmelin in his enlarged edition of the Systema Naturæ of Linnæus. The account, however, given by Mons. Sonnerat, its first describer, seems to prove it a species of lemur. It measures from fourteen to eighteen inches from the nose to the tail, which is about the same length. The general colour of the animal is a pale ferruginous-brown, mixed with black and grey; on the head, round the eyes, and on the upper parts of the body, the ferruginous brown prevails, with a blackish cast on the back and limbs; the tail is entirely black; the sides of the head, the neck, the lower jaw, and the belly, are greyish. There are also a kind of woolly hairs of this colour, and of two or three inches in length, scattered over the whole body; the thighs and legs have a reddish cast; the black prevails on the feet, which are covered with short hairs of that colour; the head is shaped like that of a squirrel; and there are two cutting-teeth in front of each jaw; the ears are large, round, and naked, resembling those of a bat, and of a black colour. The feet are long, and somewhat resemble those of the Tarsier; the thumbs or interior toes of the hind feet are short, and furnished with flat round nails, as in the macaucos; but the principal character of the animal consists in the

village, of a young leveret suckled and nursed by a cat, which received it very early under her protection, and continued to guard it with maternal solicitude till it was grown to a considerable size.

A most singular variety of this animal is sometimes found, which is furnished with rough and slightly branched horns, bearing a considerable resemblance to those of a roebuck. This particularity, as strange as it is uncommon, seems to imply a kind of indistinct approach in this animal to the order pecora.

The hare is a short-lived animal, and is supposed rarely to exceed the term of seven or eight years.

It may be proper to add, that in very severe winters, and especially in those of the more northern regions, the hare becomes entirely white, in which state it is liable to be mistaken for the following species.

2. Lepus variabilis, varying hare. This species is an inhabitant of the loftiest alpine tracts in the northern regions of the globe; occurring in Norway, Lapland, Russia, Siberia, and Kamtschatka, and on the alps of Scotland. The same species is also found in America, appearing in some parts of Canada. In its general appearance it bears an extreme resemblance to the common hare, but is of smaller size, and has shorter ears and more slender legs. Its colour in summer is a tawny grey; in winter entirely white, except the tips of the ears, which are black; the soles of the feet are also black, but are very thickly covered with a yellowish fur. This animal is observed to confine itself altogether to elevated situations, and never to descend into the plains, or to mix with the common hare. The change of colour commences in the month of September, and the grey or summer coat reappears in April; but in the very severe climate of Siberia it continues white all the year round. It has been sometimes found entirely coal-black, a variety which is also known to take place occasionally in the common hare. The varying hare sometimes migrates in order to obtain food in severe seasons. Troops of five or six hundred have been seen to quit in this manner the frozen hills of Siberia, and to descend into the plains and woody districts, from which they again return in spring to the mountains.

3. Lepus Americanus, American hare. This animal is not much superior in size to a rabbit, measuring about eighteen inches. Its colour nearly resembles that of the common hare, to which it seems much allied: but the fore legs are shorter, and the hind ones longer in proportion. The belly is white; the tail black above and white beneath; the ears tipped with grey, and the legs of a pale-ferruginous colour. It is said to inhabit all parts of North America; and in the more temperate regions retains its colour all the year round, but in the colder parts becomes white in winter, when the fur grows extremely long and silvery; the edges of the ears alone retaining their former colour. It is said to be extremely common at Hudson's Bay, where it is considered as a highly useful article of food. It breeds once or twice a year, producing from five to seven at a time. It is not of a migratory nature, but always continues to haunt the same places, taking occasional refuge under the roots of trees, or in the hollows near their roots.

4. Lepus cuniculus, rabbit. The rabbit bears a very strong general resemblance to the hare, but is considerably smaller, and its fore feet are furnished with sharper and longer claws in proportion; thus enabling it to burrow in the ground, and to form convenient retreats, in which it conceals by day, and like the hare, comes out chiefly by night and during the early part of the morning to feed. Its colour, in the wild state, is a dusky brown, paler or whitish on the under parts, and the tail is black above and white below. In a domestic state the animal varies into black, black-and-white, silvery-grey, perfectly white, &c.

The rabbit is a native of most of the temperate and warmer parts of the old continent, but is not found in the northern regions, and is not originally a native of Britain, but was introduced from other countries. Its general residence is in dry, chalky, or gravelly soils, in which it can conveniently burrow. It is so prolific an animal that it has been known to breed seven times in a year, and to produce no less than eight young each time. It is therefore not surprising, that in some countries it has been considered as a kind of calamity, and that various arts of extirpation have been practised against it.

5. Lepus viscaccia. This species is said to have the general appearance of a rabbit, but has a long bushy and bristly tail, like that of a fox, which the animal also resembles in colour; the fur on all parts, except the tail, is soft, and is used by the Peruvians in the manufacture of hats; it was also used by the ancient Peruvians for the fabric of garments, worn only by persons of distinction. In its manners this animal resembles the rabbit, burrowing under ground, and forming a double mansion, in the upper of which it deposits its provisions, and sleeps in the other. It appears chiefly by night, and is said to defend itself when attacked by striking with its tail.

6. Lepus alpinus, alpine hare. This is a very different species from the alpine hare described by Mr. Pennant in the British Zoology, which is no other than the varying hare. The alpine hare is a far smaller animal, scarcely exceeding a guinea-pig (cavia cobaya) in size, and measuring only nine inches in length. Its colour is a bright ferruginous grey, paler beneath; the head is long, and the ears short, broad, and rounded. See Plate LXXVII. Nat. Hist. fig. 246. It appears to have been first described by Dr. Pallas, who informs us that it is a native of the Altaic mountains, and extends to the Lake Baikal, and even to Kamtschatka, inhabiting rough woody tracts amidst rocks and cataracts, and forming burrows beneath the rocks, or inhabiting the natural fissures, and dwelling sometimes singly, and sometimes two or three together. In their manners they greatly resemble some of the marmots or hamsters; preparing, during the autumn, a plentiful assortment of the finest herbs and grasses, which they collect in company, and after drying with great care in the sun, dispose into heaps of very considerable size, for their winter support; and which may always be distinguished, even through the deep snow, having the appearance of so many hay ricks in miniature, and being often several feet in height and breadth. The alpine hare varies in size according to the different regions in which it is found, being largest about the Altaic mountains, and smaller about Lake Baikal, &c.

7. Lepus ogotona, ogotona hare. This animal, says Dr. Pallas, is called by the Mongolians by the name of ogotona, and is an inhabitant of rocky mountains, or

sandy plains, burrowing under the soil, or concealing itself under heaps of stones, and forming a soft nest at no great depth from the surface. It wanders about chiefly by night, and sometimes appears by day, especially in cloudy weather. In autumn it collects heaps of various vegetables for its winter food, in the same manner as the alpine hare before described, disposing them into neat hemispherical heaps of about a foot in diameter. These heaps are prepared in the month of September, and are entirely consumed by the end of winter.

The ogotona hare is about six inches or somewhat more in length, and is of a pale brown colour above, and white beneath; on the nose is a yellowish spot, and the outsides of the limbs and space about the rump are of the same colour. It is entirely destitute of a tail. See Plate LXXVII. Nat. Hist. fig. 247.

8. Lepus pusillus, calling hare. In its form this species extremely resembles the ogotona hare, but is smaller, measuring near six inches, but weighing only from three ounces and a quarter to four and a half, and in winter two and a half. It is an inhabitant of the south-east parts of Russia, and about all the ridge of hills spreading southward from the Uralian chain; as well as about the Irtish, and the west part of the Altaic chain. It is an animal of a solitary disposition, and is very rarely to be seen, even in the places it most frequents.

Lepus, in astronomy, a constellation of the southern hemisphere, comprehending 12 stars according to Ptolemy; thirteen, according to Tycho; and nineteen in the Britannic catalogue.

LERCHEA, a genus of the class and order monadelphia pentandria. The cal. is five-toothed; cor. funnel-form, five-cleft; anthers, five; style, one; caps. three-celled, many-seeded. There is one species, a shrub of the East Indies.

LERNEA, in zoology; a genus of insects of the order of vermes mollusca, the characters of which are: the body fixes itself by its tentacula, is oblong, and rather tapering; there are two ovaries like tails, and the tentacula are shaped like arms. The cyprinacea has four tentacula, two of which are lunulated at the top. It is a small species, about half an inch long, and of the thickness of a small straw. It is found on the sides of the bream, carp, and roach, in many of our ponds and rivers, in great abundance. 2. The salmonea, or salmon-louse, has an ovated body, cordated thorax, and two linear arms, approaching nearly to each other. 3. The asellina, has a lunated body and cordated thorax; and inhabits the gills of the cod-fish and ling of the northern ocean.

LESKIA, a genus of the class and order cryptogamia musci; a moss of little note.

LESSOR and Lessee, in law. See Lease.

LET Fall, a word of command at sea, to put out a sail when the yard is aloft, and the sail is to come or fall down from the yard; but, in strictness, only applied to the main and fore courses, when their yards are hoisted up.

LETTER. A servant of the post-office is within the penalty of 5 Geo. III. c. 25, which makes it a capital felony to secrete a letter containing any bank note, though he has not taken the oath required by 9 Anne c. 10. But to secrete a letter containing money, is not an offence within the statutes concerning the servants of the post-office.

Letter *of credit*, is where a merchant or correspondent writes a letter to another, requesting him to credit the bearer with a certain sum of money.

Letter *of licence*, is a written permission granted to a person under embarrassment, allowing him to conduct his affairs for a certain time without being molested. Such instrument will bind all the creditors by whom it is executed, and it generally contains certain stipulations to be observed by all parties.

Letter *of attorney*, is an instrument giving to a second person the authority to do any lawful act in the stead of the maker. They are sometimes revokable and sometimes not; in the latter case the word irrevocable is inserted. The authority must be strictly pursued: and if the attorney does less than the power it shall be void; if more, it shall be good as far as the power goes, and void as to the rest; but both these rules have many exceptions. See 1 Inst. 258.

LETTERS. The rate of postage in the United States of every single letter is regulated by distance in the following proportions.

For any distance not exceeding 30 miles, 6 cents; 80 miles, 10 cents; 150 miles, $12\frac{1}{2}$ cents; 400 miles, $18\frac{1}{2}$ cents; and for any distance over 400 miles, 25 cents.

No allowance to be made for intermediate miles. Every double letter is to pay double the said rates; every triple letter, triple; every packet weighing one ounce or upwards, at the rate of four single letters each ounce. Every ship letter originally received at an office for delivery, 6 cents. Magazines and pamphlets, not over 50 miles, 1 cent per sheet; over 50 miles and not exceeding 100, $1\frac{1}{2}$ cents; over 100 miles, 2 cents. All letters or packets weighing not more than three pounds may be sent by the post; if heavier, at the discretion of the post-master general.

The master of every vessel arriving at any port in the United States where a post-office is established, before he is permitted to report, make entry, or break bulk, is bound to deliver to the post-master all letters directed to any person within the United States, which may be under his care or within his power, except such as are for the owner or consignee of the vessel, or are directed to be delivered at the port of delivery to which the vessel is bound, and he is to make oath or affirmation before the collector to that effect.

Letters, *threatening*. To send letters threatening to accuse a person of any crime punishable with death or any infamous punishment, and knowingly to send any anonymous or fictitious letter threatening to kill any one, or set fire to their tenements or property, with a view of extorting money or valuables from them, is in the first instance punishable with fine, pillory, whipping, or transportation for seven years, and in the other instance is felony without benefit of clergy.

Letters *patent*. See Patents, and Exemplification of Patents.

Letters, *close*, are grants of the king specially distinguished from letters patent, in that the letters close, being not of public concern, but directed to particular persons, are closed up and sealed.

LETTERS *of marque*, are extraordinary commissions, granted to captains or merchants for reprisals, in order to make a reparation for those damages they have sustained, or the goods they have been deprived of by strangers at sea.

These appear to be always joined to those of reprise, for the reparation of a private injury; but under a declared war the former only are required.

LETHARGY. See MEDICINE.

LEVARI FACIAS, is a writ directed to the sheriff for levying a certain sum of money upon the lands, &c. of a person who has forfeited his recognizance.

LEUCITE. This stone is usually found in volcanic productions, and is very abundant in the neighbourhood of Vesuvius. It is always crystallized. The primitive form of its crystals is either a cube or a rhomboidal dodecahedron, and its integrant molecules are tetrahedrons; but the varieties hitherto observed are all polyhedrons. The most common has a spheroidal figure, and is bounded by 24 equal and similar trapezoids; sometimes the faces are 12, 18, 36, 54, and triangular, pentagonal, &c. The crystals vary from the size of a pin's head to that of an inch.

The texture of the leucite is foliated; its fracture somewhat conchoidal; specific gravity from 2.455 to 2.490; colour white, or greyish white. Its powder causes syrup of violets to assume a green colour. Infusible by the blowpipe. Gives a white transparent glass with borax. It is composed, as Klaproth has shown of

54 silica
23 allumina
22 potass
—
99.

It was by analysing this stone that Klaproth discovered the presence of potass in the mineral kingdom, which is not the least important of the numerous discoveries of that accurate and illustrious chemist.

Leucite is found sometimes in rocks which have never been exposed to volcanic fire; and Mr. Dolomieu has rendered it probable, from the substances in which it is found, that the leucite of volcanoes has not been formed by volcanic fire, but that it existed previously in the rocks upon which the volcanoes have acted, and that it was thrown out unaltered in fragments of these rocks.

LEUCOJUM, *great snow-drop*, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the ninth order, spathaceæ. The corolla is campanulated, sexpartite, the segments increased at the points, the stigma simple. The species are, 1. The vernum; or spring leucojum, has an oblong bulbous root, sending up a naked stalk, about a foot high, terminated by a spatha, protruding one or two white flowers, appearing in March. 2. The æstivum, or summer leucojum, has a large oblong bulbous root, an upright stalk, 15 or 18 inches high, terminated by many white flowers in May. 3. The autumnale has a large oblong bulbous root, narrow leaves, an upright stalk, terminated by white flowers in autumn. 4. The shumosum, with flowers white within, purplish without.

LEUCOMA. See SURGERY.

LEVEL, an instrument used to make a line parallel to the horizon, and to continue it out at pleasure; and by this means to find the true level, or the difference of ascent or descent, between two or more places, for conveying water, draining fens, &c.

There are several instruments, of different contrivance and matter, invented for the perfection of levelling; but they may be reduced to the following kinds.

Water-LEVEL; that which shows the horizontal line by means of a surface of water or other fluid, founded on this principle, that water always places itself level or horizontal.

The most simple kind is made of a long wooden trough or canal, which being equally filled with water, its surface shows the line of level.

The water-level is also made with two cups fitted to the two ends of a straight pipe, about an inch diameter, and three or four feet long, by means of which the water communicates from one cup to the other; and this pipe being moveable on its stand by means of a ball and socket, when the two cups show equally full of water, their two surfaces mark the line of level.

This instrument, instead of cups, may also be made with two short cylinders of glass three or four inches long, fastened to each extremity of the pipe with wax or mastic. The pipe is filled with common or coloured water, which show itself through the cylinders, by means of which the line of level is determined; the height of the water, with respect to the centre of the earth, being always the same in both cylinders. This level, though very simple, is yet very commodious for levelling small distances.

Air-LEVEL, that which shows the line of level by means of a bubble of air inclosed with some fluid in a glass tube of an indeterminate length and thickness, and having its two ends hermetically sealed. When the bubble fixes itself at a certain mark, made exactly in the middle of a tube, the case or ruler in which it is fixed is then level. When it is not level, the bubble will rise to one end. This glass tube may be set in another of brass, having an aperture in the middle, where the bubble of air may be observed. It should be filled with a liquid not liable to freeze or evaporate.

There is one of these instruments with sights, being an improvement upon that last described, which, by the addition of other apparatus, becomes more exact and commodious. It consists of an air-level (Plate LXXVIII. Miscel. fig. 146) about eight inches long, and about two-thirds of an inch in diameter, set in a brass tube 2, having an aperture in the middle C. The tubes are carried in a straight ruler, of a foot long; at the ends of which are fixed two sights 3, 3, exactly perpendicular to the tubes, and of an equal height, having a square hole, formed by two fillets of brass crossing each other at right angles; in the middle of this is drilled a very small hole, through which a point on a level with the instrument is seen. The brass tube is fastened to the ruler by means of two screws: the one of which, marked 4, serves to raise or depress the tube at pleasure, for bringing it towards a level. The top of the ball and socket is rivetted to a small ruler that springs, one end of which is fastened with springs, to the great ruler, and at the other end is a screw 5, serving to raise and depress the instrument when nearly level.

But this instrument is still less commodious than the

following one: for though the holes are ever so small, yet they will still take in too great a space to determine the point of level precisely.

Fig. 147. is a level with telescopic sights, first invented by Mr. Huygens. It is like the last, with this difference, that instead of plain sights it carries a telescope to determine exactly a point of level at a considerable distance. The screw 3, is for raising or lowering a little fork for carrying the hair, and making it agree with the bubble of air when the instrument is level; and the screw 4 is for making the bubble of air, D or E, agree with the telescope. The whole is fitted to a ball and socket, or otherwise moved by joints and screws. It may be observed, that a telescope may be added to any kind of level, or by applying it upon, or parallel to, the base or rule, when there is occasion to take the level of remote objects; and it possesses this advantage, that it may be inverted by turning the ruler and telescope half-round; and if then the hair cut the same point that it did before, the operation is just. Many varieties and improvements of this instrument have been made by the more modern opticians.

Dr. Desaguiliers proposed a machine for taking the difference of level, which contained the principles both of a barometer and thermometer; but it is not accurate in practice.

Reflecting Level, that made by means of a pretty long surface of water, representing the same object inverted, which we see erect by the eye; so that the point where these two objects appear to meet, is on a level with the place where the surface of the water is found.

There is another reflecting level, consisting of a polished metal mirror, placed a little before the object-glass of a telescope, suspended perpendicularly. This mirror must be set at an angle of 45 degrees; in which case the perpendicular line of the telescope becomes a horizontal line, or a line of level; which is the invention of M. Cassini.

Artillery Foot-Level, is in form of a square (fig. 148.), having its two legs or branches of an equal length; at the junction of which is a small hole, by which hangs a plummet playing on a perpendicular line in the middle of a quadrant, which is divided both ways from that point into 45 degrees.

This instrument may be used to other occasions by placing the ends of its two branches on a plane; for when the plummet plays perpendicularly over the middle division of the quadrant, the plane is then level.

To use it in gunnery, place the two ends on the piece of artillery, which may be raised to any proposed height by means of the plummet, which will cut the degree above the level. But this supposes the outside of the cannon is parallel to its axis, which is not always the case; and therefore they use another instrument now, either to set the piece level, or elevate it at any angle; namely, a small quadrant, with one of its radii continued out pretty long, which being put into the inside of the cylindrical bore, the plummet shows the angle of elevation, or the line of level.

Carpenter's, *Bricklayer's*, or *Pavior's* Level, consists of a long ruler, in the middle of which is fitted at right angles another broader piece, at the top of which is fastened a plummet, which when it hangs over the middle line of the second or upright piece, shows that the base or long ruler is horizontal or level. Fig. 149.

Mason's Level, is composed of three rulers, so jointed as to form an isoceles triangle, somewhat like a Roman A; from the vertex of which is suspended a plummet, which hangs directly over a mark in the middle of the base, when this is horizontal or level.

Plum or *Pendulum* Level, said to be invented by M. Picard, fig. 130. This shows the horizontal line by means of another line perpendicular to that described by a plummet or pendulum. This level consists of two legs or branches, joined at right angles, the one of which, of about 18 inches long, carries a thread and plummet; the thread being hung near the top of the branch, at the point 2. The middle of the branch where the thread passes is hollow, so that it may hang free from every where: but towards the bottom, where there is a small blade of silver, on which a line is drawn perpendicular to the telescope, the said cavity is covered by two pieces of brass, with a piece of glass G, to see the plummet through, forming a kind of case, to prevent the wind from agitating the thread. The telescope, of a proper length, is fixed to the other leg of the instrument, at right angles to the perpendicular, and having a hair stretched horizontally across the focus of the object-glass, which determines the point of level, when the string of the plummet hangs against the line on the silver blade. The whole is fixed by a ball and socket to its stand.

Fig. 151. is a *Balance* Level, which being suspended by the ring, the two sights, when in equilibrio, will be horizontal, or in a level.

But the most complete level is the *Spirits* Level, invented by the late Mr. Ramsden. See Plate LXXVI. Spirits Level. ABD, fig. 7. are the three legs upon which it is placed; when shut up, they form one round rod, and are kept together by three rings: these legs are jointed to a brass frame E, on the top of which is a male screw, screwing into a female screw within the projection *a* of the plate F. Within the top of *a*, figs. 4 and 7, is a hemispherical cavity to contain the spherical ball, fig. 5: this ball has a male screw *d* on its top, which screws into a female screw *b*, fig. 6, in the plate G, fig. 7 and fig. 6, the ball is put up through an opening *e*, fig. 4, and screwed to the plate, fig. 6; so that the upper plate G can move in any direction within certain limits by the play of the ball in its socket; to confine the upper plate G when it is set in any direction, four screws, HHHH, figs. 4 and 7, are employed; they work in tubes firmly fixed to the plate F, and are turned by their milled heads; the upper ends of these screws act against the under side of the plate, fig. 6, as shown in fig. 7; so that when the plate G is required to be moved in any direction, it is done by screwing up one screw and screwing down the opposite till it is brought to the proper inclination; then by screwing up both together, the plate is firmly fixed. The ball, fig. 5, has a conical hole *f* through it, to receive an axis which is screwed fast to the bottom of the compass-box I, fig. 7; a screw screwed into the end of this axis prevents its being lifted out, and at the same time leaves it at liberty to turn round independant of the ball, fig. 5. On each side of the compass-box I, is a bar KK, on the end of which are fixed two forked pieces 10, called the Y's (from their resemblance to that letter), carrying

the telescope M. One of these (O) is capable of being raised or lowered by means of a milled-headed screw N, which works through a collar in the lower end of the tube *g;* the rest of the tube has a triangular hole through it, in which slides a bar *k*, which is part of the Y; O the female screw is cut within this bar, and the screw works into it, so that by turning the milled head one way, the Y is raised, and by reversing the motion, it is lowered. The axis which connects the compass-box and the other apparatus, has a collar upon it just above where it enters the ball, fig. 5, which is embraced by a clamp P, fig. 6, which is closed by a screw C, so as to hold the collar of the axis quite tight; and when the screw is turned back, its own elasticity opens it so as to allow the axis of the compass-box to turn round freely within it; on the opposite side of the clamp is a projecting arm *l*, carrying the nut *m* of the screw Q, which screw works in a stud *n*, fixed to the upper plate G, figs. 7 and 6; by this means, when G is loosened, the telescope can be turned quite round, but when it is fastened, it can only be moved by turning the screw Q. The level-tube Z is fastened to the under side of the telescope by a screw *q* at one end and a bar *r* at the other: the use of these are to adjust it so that it shall be exactly parallel to the axis of the telescope-tube. The level, as best explained in the section, fig. 1, is a tube of glass *ss*, nearly filled with spirits of wine, but so as to leave a bubble of air in it; if the tube is of exactly the same diameter in every part, the bubble will rest in the middle of the tube when it is level. In some of the best levels made by Ramsden, the inside of the tube is bent into a segment of a circle, 100 feet diameter, and the inside is ground, which causes the bubble to adhere together; if the tube is straight, it is liable to divide into several small ones. The internal parts of the telescope are explained in fig. 1: RR is the external tube of brass plate; within this slides another tube *ss*; it has two glasses *v*, *w*, screwed into the outer end, called object-glasses, and it has two divisions *x*, *y*, called diaphagram, with small holes in them; their use is to collect the prismatic rays with which the objects would otherwise be tinged; the tube *ss* has a rack *t* fixed nearly in the middle of it, which takes into a pinion on the axis of the milled head T, figs. 1 and 7; by turning this, the glasses *v*, *w*, can be moved nearer to, or farther from, the eye to adjust the focus; to the tube R at *v* are fixed the cross wires, whose intersection is exactly in the centre of the tube. The manner of fixing these is explained in fig. 3: A is a brass box, which fits into the end of the telescope-tube, and is held there by four small screws; within this box is placed a brass plate B, carrying the wires, which are fastened by screwing four screws down upon their ends; when the plate B is in the box, a ring D is screwed in upon it, which prevents its falling out, but at the same time leaves it at liberty to move about in the box; the sides of the box, and also the telescope-tube, has four rectangular holes in it, through which four screws are passed into the edges of the piece B, so as to hold it in any position: these screws come through the external tube, and have square heads, to be turned by a key, so as to adjust the interactions in the centre: the box A has a female screw in the front, into which is screwed the eye-piece W; 3 is the tube which is screwed to the telescope; within this slides a tube, containing two glasses 4, 5; by sliding the glasses in or out of the tube 3, they can be adjusted so as to adopt their focus to the cross wires. This eye-piece is convenient on account of its shortness; but as it reverses the objects, it is sometimes more convenient to use the eye-piece fig. 2, which is much longer, but does not reverse objects. *a* is the tube which is screwed to the telescope; within this slides another tube *bb*, having at one end a tube *dd*, containing two glasses *ef*, and a diaphagram *g*, and at the other end a tube *hh*, containing two glasses *ik*, and a diaphagram: *m* is a cap screwed on to the end to prevent the tubes coming out. When the instrument is to be carried, the level is unscrewed from the legs and packed in a case; the legs are shut up and kept so by the rings, as before described. The manner of using this instrument is as follows: When the difference of level between any two places is required, the observer with the level goes to the highest of the two, and his assistant goes to the lowest with the target, which is a long pole of wood with a groove in it, in which slides a small rod carrying a round piece of wood, called a sight, which is to be observed through the telescope; the observer opens the legs of the instrument, and sets them on the ground; the level is next screwed to them at E, as shown in fig. 7; the telescope is then brought nearly to a level by the screws HHHH, as before described; the screw *c* is then turned so as to release the clamp P, fig. 6; and the telescope is turned about, so as to point to the target; the clamp P is then closed, the observer looks through the telescope, and by turning the nut T, the focus is adjusted: the screw Q is then turned till the cross wires are brought to coincide with the object, in an horizontal plane; he then takes his eye from the telescope, and works the screw N till he brings the bubble of air in the level-tube exactly in the middle, which shows that the telescope is perfectly horizontal; the observer then makes signals to the assistant to raise or lower the sight on the slider of the target, till it is brought to coincide with the intersection of the cross wire, which shows that the telescope and the sight of the target are on the same level; the height which the sight is from the ground where the target stands, deducted from the height the telescope stands from the ground, is the difference of level required.

LEVELLING, the art or act of finding a line parallel to the horizon at one or more stations, to determine the height or depth of one place with respect to another; for laying out grounds even, regulating descents, draining morasses, conducting water, &c.

Two or more places are on a true level when they are equally distant from the centre of the earth. Also one place is higher than another, or out of level with it, when it is farther from the centre of the earth; and a line equally distant from that centre in all its points, is called the line of true level. Hence, because the earth is round, that line must be a curve, and make a part of the earth's circumference, or at least parallel to it, or concentrical with it; as the line BCFG Plate LXXVIII. Misc. fig. 152), which has all its points equally distant from A, the centre of the earth, considering it as a perfect globe.

But the line of sight BDE, &c. given by the operations of levels, is a tangent, or a right line perpendicular to the semidiameter of the earth at the point of contact B, rising always higher above the true line of level, the farther the distance is, is called the apparent line of level.

Thus, CD is the height of the apparent level above the true level, at the distance BC or BD; also EF is the excess of height at F, and GH at G, &c. The difference, it is evident, is always equal to the excess of the secant of the arch of distance above the radius of the earth.

The common methods of levelling are sufficient for laying pavements of walks, or for conveying water to small distances, &c.; but in more extensive operations, as in levelling the bottoms of canals, which are to convey water to the distance of many miles, and such like, the difference between the true and the apparent level must be taken into the account.

Now the difference CD between the true and apparent level, at any distance BC or BD, may be found thus: By a well-known property of the circle, 2AC + CD : BD : : BD : CD; or because the diameter of the earth is so great with respect to the line CD at all distances to which an operation of levelling commonly extends, that 2AC may be safely taken for 2AC + CD in that proportion without any sensible error, it will be 2AC : BD : : BD : CD, which therefore is $= \frac{BD^2}{2AC}$, or $\frac{BC^2}{2AC}$ nearly; that is, the difference between the true and apparent level, is equal to the square of the distance between the places, divided by the diameter of the earth; and consequently it is always proportional to the square of the distance.

Now the diameter of the earth being nearly 7958 miles; if we first take BC = 1 mile, then the excess $\frac{BC^2}{2AC}$ becomes $\frac{1}{7958}$ of a mile, which is 7.962 inches, or almost 8 inches, for the height of the apparent above the true level at the distance of one mile. Hence, proportioning the excesses in altitude according to the squares of the distances, the following Table is obtained, showing the height of the apparent above the true level for every 100 yards of distance on the one hand, and for every mile on the other.

Dist. or BC.	Dif. of Level, or CD.	Dist. or BC.	Dif of Level, or CD.	
Yards	Inches.	Miles.	Feet.	Inc.
100	0.026	$\frac{1}{4}$	0	$0\frac{1}{2}$
200	0.103	$\frac{1}{2}$	0	2
300	0.231	$\frac{3}{4}$	0	$4\frac{1}{2}$
400	0.411	1	0	8
500	0.643	2	2	8
600	0.925	3	6	0
700	1.260	4	10	7
800	1.645	5	16	7
900	2.081	6	23	11
1000	2.570	7	32	6
1100	3.110	8	42	6
1200	3.701	9	53	9
1300	4.344	10	66	4
1400	5.038	11	80	3
1500	5.784	12	95	7
1600	6.580	13	112	2
1700	7.425	14	130	1

By means of tables of reductions, we can now level to almost any distance at one operation, which the ancients could not do but by a great multitude; for, being unacquainted with the correction answering to any distance, they only levelled from one 20 yards to another, when they had occasion to continue the work to some considerable extent.

This table will answer several useful purposes. Thus, first, to find the height of the apparent level above the true, at any distance. If the given distance is in the table, the correction of level is found on the same line with it: thus at the distance of 1000 yards, the correction is 2.57, or two inches and a half nearly; and at the distance of 10 miles, it is 66 feet 4 inches. But if the exact distance is not found in the table, then multiply the square of the distance in yards by 2.57 and divide by 1,000,000, or cut off six places on the right for decimals; the rest are inches: or multiply the square of the distance in miles by 66 feet 4 inches, and divide by 100.

2dly, To find the extent of the visible horison, or how far can be seen from any given height, on a horizontal plane, as at sea, &c. Suppose the eye of an observer, on the top of a ship's mast at sea, is at the height of 130 feet above the water, he will then see about 14 miles all around. Or from the top of a cliff by the sea-side, the height of which is 66 feet, a person may see to the distance of near 10 miles on the surface of the sea. Also, when the top of a hill, or the light in a light-house, or such like, whose height is 130 feet, first comes into the view of an eye on board a ship, the table shows that the distance of the ship from it is 14 miles, if the eye is at the surface of the water; but if the height of the eye in the ship is 80 feet, then the distance will be increased by near 11 miles, making in all about 25 miles distance.

3dly, Suppose a spring to be on one side of a hill, and a house on an opposite hill. with a valley between them, and that the spring seen from the house appears by a levelling instrument to be on a level with the foundation of the house, which suppose is at a mile distance from it; then is the spring eight inches above the true level of the house; and this difference would be barely sufficient for the water to be brought in pipes from the spring to the house, the pipes being laid all the way in the ground.

4th, If the height or distance exceed the limits of the table, then, first, if the distance be given. divide it by 2, or by 3, or by 4, &c. till the quotient come within the distances in the table; then take out the height answering to the quotient, and multiply it by the square of the divisor, that is, by 4, or 9, or 16, &c. for the height required: so if the top of a hill is just seen at the distance of 40 miles, then 40 divided by 4 gives 10, to which in the table answer $66\frac{1}{3}$ feet. which being multiplied by 16, the square of 4, gives $1061\frac{1}{3}$ feet for the height of the hill. But when the height is given. divide it by one of these square numbers 4, 9, 16, 25. &c. till the quotient come within the limits of the table, and multiply the quotient by the square root of the divisor, that is by 2. or 3, or 4, or 5, &c. for the distance sought: so when the top of the peak of Teneriffe, said to be almost 3 miles, or 15840 feet high, just comes into view at sea, divide 15840 by 225, or the square of 15, and the quotient is 70 nearly: to which in the table answers by proportion nearly $10\frac{2}{7}$ miles; then multiplying $10\frac{2}{7}$ by 15, gives 154 miles and $\frac{2}{7}$, for the distance of the hill.

The operation of levelling is as follows: Suppose the height of the point A (Plate LXXVIII. Misc. fig. 153,) on the top of a mountain, above that of B at the foot of it, is required. Place the level about the middle distance at D, and set up pickets, poles, or staffs at A and B, where persons must attend with signals for raising and lowering, on the said poles, little marks of pasteboard or other matter. The level having been placed horizontally by the bubble, &c. look towards the staff AE, and cause the person there to raise or lower the mark till it appears through the telescope or sights, &c. at E: then measure exactly the perpendicular height of the point E above the point A, which suppose 5 feet 8 inches, and set it down in your book. Then turn your view the other way towards the pole B, and cause the person there to raise or lower his mark, till it appears in the visual line as before at C; and measuring the height of C above B, which suppose 15 feet 6 inches, set this down in your book also, immediately above the number of the first observation. Then subtract the one from the other, and the remainder 9 feet 10 inches will be the difference of level between A and B, or the height of the point A above the point B.

If the point D, where the instrument is fixed, is exactly in the middle between the points A and B, there will be no necessity for reducing the apparent level to the true one, the visual ray on both sides being raised equally above the true level. But if not, each height must be corrected or reduced according to its distance, before the one corrected height is subtracted from the other.

When the distance is very considerable or irregular, so that the operation cannot be effected at once placing of the level, or when it is required to know if there is a sufficient descent for conveying water from the spring A to the point B (fig. 154.), this must be performed at several operations. Having chosen a proper place for the first station, as at I, fix a pole at the point A near the spring, with a proper mark to slide up and down it, as L; and measure the distance from A to I. Then the level being adjusted in the point T, let the mark L be raised or lowered till it is seen through the telescope or sights of the level. and measure the height AL. Then having fixed another pole at H, direct the level to it, and cause the mark G to be moved up or down till it appears through the instrument; then measure the height GH, and the distance from I to H, noting them down in the book. This done, remove the level forwards to some other eminence as E, from whence the pole H may be viewed, as also another pole at D; then having adjusted the level in the point E, look back to the pole H; and managing the mark as before, the visual ray will give the point F; then measuring the distance HE and the height HF, note them down in the book. Then, turning the level to look at the next pole D, the visual ray will give the point D; there measure the height of D. and the distance EB, entering them in the book as before. And thus proceed from one station to another till the whole is completed.

But all these heights must be corrected or reduced by the foregoing table, according to their respective distances and heights, with their corrections entered in the book, in the following manner:

Back-sights.					Fore-sights.				
Dists.	Hts.			Cors	Dists.	Hts.			Cors
yds		ft.	in.	inc.	yds.		ft.	in.	inc.
IA 1650	AL	11	3	7.0	IH 1265	HG	19	5	4.0
EH 940	HF	10	7	2.2	EB 900	BD	8	1	2.1
2590		21	10	9.2	2165		27	6	6.1
			9.2		2590			6.1	
		21	0.8		Dist. 4755		26	11.9	
							21	0.8	
					Whole dif. of level		5	11.1	

Having summed up all the columns, add those of the distances together, and the whole distance from A to B is 4755 yards, or two miles and three quarters nearly. Then the sums of the corrections taken from the sums of the apparent heights, leave the two corrected heights; the one of which being taken from the other, leaves 5 feet 11.1 inches for the true difference of level sought between the two places A and B, which is at the rate of an inch and a half nearly to every 100 yards, a quantity more than sufficient to cause the water to run from the spring to the house.

Or the operation may be otherwise performed, thus: Instead of placing the level between every two poles, and taking both back-sights and fore-sights, plant it first at the spring A, and from thence observe the level to the first pole; then move it to this pole, and observe the second pole; next remove it to the second pole, and observe the third pole; and so on, from one pole to another, always taking foreward sights or observations only. And then at the last, add all the corrected heights together, and the sum will be the whole difference of level sought.

Levelling-staves, instruments used in levelling, serving to carry the marks to be observed, and at the same time to measure the heights of those marks from the ground. They usually consist each of two long wooden rulers, made to slide over one another, and divided into feet, inches, &c.

LEVER. See Mechanics.

LEVIGATION. See Pharmacy.

LEVISANUS, a genus of the class and order pentandria monogynia. The flowers are aggregate; corolla one-leafed, superior, five-cleft; filaments inserted into the base of the perianthium; styles two, conjoined; seeds five or six. There are five species, shrubs of the Cape.

LEYDEN PHIAL. See Electricity.

LEYSERA, a genus of the polygamia superflua order, in the syngenesia clase of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the pappus paleaceous; that of the disc plumy; the calyx scarious. There are three species, shrubs of the Cape.

LIATRIS, a genus of the class and order syngenesia polygamia æqualis. The calyx is oblong, imbricate, awnless, coloured down, feathered coloured; receptacle naked,

hollow dotted. There are eight species, herbs of America.

LIBEL, injurious reproaches or accusations written and published against the memory of one who is dead, or the reputation of one who is alive, and thereby exposing him to public hatred, contempt, and ridicule.

With regard to libels in general, there are, as in many other cases, two remedies; one by indictment or inforformation, and the other by action. The former for a public offence; for every libel has a tendency to the breach of the peace, by provoking the person libelled to break it; which offence is said to be the same in point of law, whether the matter contained is true or false; and therefore it is that the defendant on an indictment for publishing a libel, is not allowed to allege the truth of it by way of justification. But in the remedy by action on the case, which is to repair the party in damages for the injury done him, the defendant may, as for words spoken, justify the truth of the facts, and show that the plaintiff has received no injury at all. The chief excellence therefore of a civil action for a libel consists in this, that it not only affords a reparation for the injury sustained, but is a full vindication of the innocence of the person traduced. 3 Black. 125.

By a late statute, the jury are acknowledged to be judges both of the law and the fact.

Libel, in the ecclesiastical court, is the declaration or charge drawn up in writing, on the part of the plaintiff, to which the defendant is obliged to answer.

Libel, in the law of Scotland, signifies an indictment.

LIBELLULA, *dragon-fly*, a genus of insects of the order neuroptera. The generic character is: mouth furnished with several jaws; antennæ very short; wings four, extended; tail (in the male) hook-forcipated.

The libellulæ, or dragon-flies, sometimes called by the very improper title of horse-stingers, exhibit an instance scarcely less striking than the butterfly of that strange dissimilitude in point of form under which one and the same animal is destined to appear in the different periods of its existence. Perhaps few persons not particularly conversant in the history of insects, would imagine that these highly brilliant and lively animals, which may be seen flying with such strength and rapidity round the meadows, and pursuing the smaller insects with the velocity of a hawk, had once been inhabitants of the water, and that they had resided for a long space of time in that element before they assumed their flying form. Of the libellulæ there are many different species, both native and exotic. The most remarkable of the English species is the libellula varia, or great variegated libellula. This insect makes its appearance principally towards the decline of summer, and is an animal of singular beauty: its general length is about three inches from head to tail, and the wings, when expanded, measure near four inches from tip to tip; the head is very large, and affixed to the thorax by an extremely slender neck; the eyes occupy by far the greatest part of the head, and are of a pearly blue-grey cast, with a varying lustre; the front is greenish yellow; the thorax of the same colour, but marked by longitudinal black streaks; the body, which is very long, slender, and subcylindrical, is black, with rich variegations of bright blue, and deep grass-green; the wings are perfectly transparent, strengthened by very numerous black retigular fibres, and exhibit a strongly iridescent appearance, according to the various inflexions of light; each is marked near the tip by a small oblong square black spot on the outer edge; the legs are black, and the tail is terminated by a pair of black forcipated processes, with an intermediate shorter one of similar colour. Sometimes this insect varies; the spots or marks on the abdomen and thorax being red or red-brown instead of green.

The female libellula deposits or drops her eggs into the water, which sinking to the bottom, are hatched, after a certain period, into hexapode flattish larvæ or caterpillars, of a very singular and disagreeable aspect. They cast their skins several times before they arrive at their full size, and are of a dusky-brown colour. The rudiments of the future wings appear on the back of such as are advanced to what may be called the pupa or chrysalis state, in the form of a pair of oblong scales or processes, and the head is armed with a most singular organ for seizing its prey, viz. a kind of proboscis, of a flattened form, and furnished with a joint in the middle, the end being much dilated, and armed with a pair of strong hooks or prongs. This proboscis, when the animal is at rest, is folded or turned up in such a manner as to lap over the face like a mask; but when the creature sees any insect which it means to attack, it springs suddenly forwards, and by stretching forth the jointed proboscis, readily obtains its prey. They continue in this their larva and pupa state for two years, when, having attained their full size, they prepare for their ultimate change; and creeping up the stem of some water-plant, and grasping it with their feet, they make an effort, by which the skin of the back and head is forced open, and the inclosed libellula gradually emerges. The wings, at this early period of exclusion, like those of butterflies, are very short, tender and contracted, all the ramifications of fibres having been compressed within the small compass of the oblong scales on the back of the larva, or pupa; but in the space of about half an hour, they are fully expanded, and have acquired the solidity and strength necessary for flight. This curious process of the evolution or birth of the libellula generally takes place in the morning, and during a clear sunshine. The remaining part of the animal's life is but short in comparison with that which it passed in its aquatic state, the frosts of the close of autumn destroying the whole race. They are also the prey of several sorts of birds.

The libellula depressa is a smaller or shorter species than the preceding, though with a considerably broader body in proportion. The male is of a bright sky-blue, with the sides of the body yellow; the female of a fine brown or bay, with yellow sides also. The wings in both sexes are transparent, except at the shoulders, where they are each marked by a broad bed or patch of brown with a stripe of yellow; the tips of each wing have also a small oblong-square black spot on the outer margin. The larva of this species is of a shorter form than that of the preceding, and is of a greenish-brown colour.

The libellula virgo is one of the most elegant of the European insects. It is much smaller than the libellula varia, and is distinguished by its very slender, long, cylindric body, which, as well as the head and thorax, is usually either of a bright but deep golden green, or else

of a deep gilded blue. The wings are transparent at the base and tips, but are each marked in the middle by a very large oval patch or bed of deep blackish or violet blue, accompanied with iridescent hues according to the direction of the light: sometimes the wings are entirely violet-black, without the least appearance of transparency either at the base or tips; and sometimes they are altogether transparent, without any appearance of the violet-black patch which distinguishes the majority of specimens; and lastly the insect sometimes appears with transparent wings, but shaded with a strong cast of gilded greenish brown, each being marked by a small white speck at the exterior edge, near the tip.

A much smaller species than the preceding, and equally common, is the libellula puella of Linnæus. This varies much in colour, but is generally of a bright and beautiful sky-blue, variegated with black bars on the joints, and with the thorax marked by black longitudinal stripes. The wings are transparent, and each marked near the tip with a small oblong-square black marginal spot.

The exotic libellulæ are very numerous. Among the most remarkable may be numbered the L. lucretia. It is a native of the Cape of Good Hope, and is distinguished by the excessive length of its slender body, which measures not less than five inches and a half in length, though scarcely exceeding the tenth of an inch in diameter. The wings are transparent, of a slender or narrow shape, as in the L. puella, to which this species is allied in form, and measure five inches and a half in extent from tip to tip. The colour of the head and thorax is brown, with a yellowish stripe on each side, and the body is of a deep mazarine-blue. See Plate LXXVII. Nat. Hist. figs. 250, 251.

LIBERTUS, in Roman antiquity, a person who from being a slave, had obtained his freedom. The difference between the liberti and libertini was this: the liberti were such as had been actually made free themselves, and the libertini were the children of such persons.

LIBRA, *the balance*, in astronomy, one of the twelve signs of the zodiac, the sixth in order; so called because when the sun enters it, the days and nights are equal, as if weighed in a balance.

Authors enumerate from ten to forty-nine stars in this sign.

Libra, in Roman antiquity, a pound weight; also a coin, equal in value to twenty denarii.

LIBRATION, in astronomy, an apparent irregularity of the moon's motion, whereby she seems to librate about her axis, sometimes from the east to the west, and now and then from the west to the east; so that the parts in the western limb or margin of the moon sometimes recede from the centre of the disk, and sometimes move towards it, by which means they become alternately visible and invisible to the inhabitants of the earth.

Libration *of the earth*, is sometimes used to denote the parallelism of the earth's axis, in every part of its orbit round the sun.

LICENCE, in law, an authority given to a person to do some lawful act.

A licence is a personal power, and therefore cannot be transferred to another. If the person licensed abuse the power given him, in that case he becomes a tresspasser.

LICENTIATE, one who has obtained the degree of a licence. The greatest number of the officers of justice in Spain are distinguished by no other title but that of licentiate. In order to pass licentiate in common law, civil law, and physic, they must have studied seven years; and in divinity, ten. Among us, a licentiate usually means a physician who has a licence to practise, granted by the college of physicians, or the bishop of the diocese.

LICHEN, *liverwort*, a genus of the natural order of algæ, in the cryptogamia class of plants. The male receptacle is roundish, somewhat plain and shining. In the female the leaves have a farina or mealy substance scattered over them. There are about 216 species, all found in Britain. Among the most remarkable are the following:

1. The geographicus; it is frequent in rocks, and may be readily distinguished at a distance. The crust or ground is of a bright greenish-yellow colour, sprinkled over with numerous plain black tubercles; which frequently run into one another, and form lines resembling the rivers in a map, from which last circumstance it takes it name.

2. The calcareous, or black-nobbed dyer's lichen, is frequent on calcareous rocks; and has a hard, smooth, white, stony, or tartareous crust, cracked or tesselated on the surface, with black tubercles. Dillenius relates, that this species is used in dyeing, in the same manner as the tartareous after-mentioned.

3. The ventosus, or red spangled tartareous lichen, has a hard tartareous crust, cracked and tesselated on the surface, of a pale yellow colour when fresh, and a light olive when dry. The tubercles are of a blood-red colour at top, their margin and base of the same colour as the crust. The texture and appearance of this (according to Mr. Lightfoot) indicate that it would answer the purposes of dyeing as well as some others of this tribe, if proper experiments were made.

4. The candelarius, or yellow farinaceous lichen, is common upon walls, rocks, boards, and old pales. There are two varieties. The first has a farinaceous crust of no regular figure, covered with numerous small greenish-yellow or olive shields, and grows commonly upon old boards. The other has a smooth, hard, circular crust, wrinkled and lobed at the circumference, which adheres closely to rocks and stones. In the centre are numerous shields of a deeper yellow or orange colour, which, as they grow old, swell in the middle, and assume the figure of tubercles. The inhabitants of Smaland in Sweden scrape this lichen from the rocks, and mix it with their tallow, to make golden candles to burn on festival days.

5. The tartareus, or large yellow-saucered dyer's lichen, is frequent on rocks, both in the Highlands and Lowlands of Scotland. The crust is thick and tough, either white or greenish white, and has a rough watered surface. The shields are yellow or buff-coloured, of various sizes; from that of a pin's head to the diameter of a silver penny. Their margins are of the same colour as the crust. This lichen is much used by the Highlanders for dyeing a fine claret or pompadour colour. For this purpose, after scraping it from the rocks, and cleaning it, they steep it in urine for a quarter of a year. Then taking it out, they make it into cakes, and hang them up in bags to dry. These cakes are afterwards pulverised,

and the powder is used to impart the colour with an addition of alum.

6. The parellus, or crawfish-eye lichen, grows upon walls and rocks, but is not very common. The crusts spread closely upon the place where they grow, and cover them to a considerable extent. They are rough, tartareous, and ash-coloured, of a tough coriaceous substance. The shields are numerous and crowded, having white or ash-coloured, shallow, plain discs, with obtuse margins. This is used by the French for dyeing a red colour.

7. The saxatilis, or grey-blue pitted lichen, is very common upon trunks of trees, rocks, tiles, and old wood. It forms a circle two or three inches diameter. The upper surface is of a blue grey, and sometimes of a whitish ash-colour, uneven, and full of numerous small pits or cavities; the under side is black, and covered all over, even to the edges, with short simple hairs or radicles. A variety sometimes occurs with the leaves tinged of a red or purple colour. This is used by finches and other small birds in constructing the outside of their curiously formed nests.

8. The omphalodes, or dark-coloured dyer's lichen, is frequent upon rocks. It forms a thick widely expanded crust of no regular figure, composed of numerous imbricated leaves of a brown or dark-purple colour, divided into small segments. The margins of the shields are a little crisped and turned inwards, and their outside ash-coloured. This lichen is much used by the Highlanders in dyeing a reddish-brown colour. They steep it in urine for a considerable time, till it becomes soft and like a paste; then, forming the paste into cakes, they dry them in the sun, and preserve them for use in the manner already related of the tartareous.

9. The parietinus or common yellow wall-lichen, is very common upon walls, rocks, tiles of houses, and trunks of trees. It generally spreads itself in circles of two or three inches diameter, and is said to dye a good yellow or orange-colour with alum.

10. The Islandicus, or eatable Iceland lichen, grows on many mountains both of the Highlands and Lowlands of Scotland. It consists of nearly erect leaves about two inches high, of a stiff substance when dry, but soft and pliant when moist, variously divided without order into broad distant segments, befid or trifid at the extremities. The upper or interior surface of the leaves is concave, chesnut-colour, smooth, and shining, but red at the base; the under or exterior surface is smooth and whitish, a little pitted, and sprinkled with very minute black warts. The margins of the leaves and all the segments from bottom to top, are ciliated with small, short, stiff, hair-like spinules, of a dark chesnut-colour, turning towards the upper side. The shields are very rarely produced. Made into broth or gruel, it is said to be very serviceable in coughs and consumptions; and, according to Haller and Scopoli, is much used in these complaints in Vienna.

11. The pulmonareous, or lung-wort lichen, grows in shady woods upon the trunks of old trees. The leaves are as broad as a man's hand, of a kind of leather-like substance, hanging loose from the trunk on which it grows, and lacinated into wide angular segments. Their natural colour, when fresh, is green: but in drying, they turn first to a glauceous and afterwards to a fuscous colour. It has an astringent, bitter taste; and, according to Gmelin, is boiled in ale in Siberia, instead of hops. The ancients used it in coughs and asthmas, &c. but it is not used in modern practice.

12. The calicaris, or beaked lichen, grows sometimes upon trees, but more frequently upon rocks, especially on the sea-coasts, but is not very common. It is smooth, glossy, and whitish, producing flat or convex shields, of the same colour as the leaves, very near the summits of the segments, which are acute and rigid, and, being often reflected from the perpendicular by the growth of the shields, appear from under their limbs like a hooked beak. This will dye a red colour; and promises, in that intention, to rival the famous lichen rocolla or argol, which is brought from the Canary Islands, and sometimes sold at the price of 80*l.* per ton. It was formerly used instead of starch to make hair-powder.

13. The prunastri, or common ragged hoary lichen, grows upon all sorts of trees; but it is generally most white and hoary on the sloe and old palm trees, or upon old pales. This is the most variable of the whole tribe of lichens, appearing different in figure, magnitude, and colour, according to its age, place of growth, and sex. The young plants are of a glaucous colour, slightly divided into small acute crested segments. As they grow older, they are divided like a stag's horn, into more and deeper segments, somewhat broad, flat, soft, and pitted on both sides, the upper surface of a glaucous colour, the under one white and hoary. The male plants, as Linnæus terms them, are short, seldom more than an inch high, not hoary on the under side; and have pale glaucous shields situated at the extremities of the segments, standing on short peduncles, which are only small stiff portions of the leaf produced. The female specimens have numerous farinaceous tubercles both on the edges of their leaves, and the wrinkles of their furnace. The pulverised leaves have been used as a powder for the hair, and also in dyeing yarn of a red colour.

14. The juniperinus, or common yellow tree-lichen, is common upon the trunks and branches of elms and many other trees. Linnæus says it is very common upon the juniper. The Gothland Swedes dye their yarn of a yellow colour with it, and give it as a specific in the jaundice.

15. The caninus, or ash-coloured ground liverwort, grows upon the ground among moss, at the roots of trees in shady woods, and is frequent also in heaths and stony places. The leaves are large, gradually dilated towards the extremities, and divided into roundish elevated lobes. Their upper side, in dry weather, is ash-coloured; in rainy weather, of a dull fuscous green colour; their underside white and hoary, having many thick downy nerves, from which descend numerous long, white, pencil-like radicles. The peltæ, or shields, grow at the extremities of the elevated lobes, shaped like the human nail; of a roundish oval form, convex above, and concave beneath; of a chocolate colour on the upper side, and the same colour with the leaves on the under. There are two varieties, the one called reddish, and the other many-fingered, ground-liverwort. The former is more common than the other. This species has been rendered famous by the celebrated Dr. Mead, who asserted that it was an

infallible preventative of the dreadful consequences attending the bite of a mad dog.

16. The aphthosus, or green ground liver-wort with black warts, grows upon the ground at the roots of trees in woods, and other stony and mossy places. It differs very little from the foregoing, and according to some is only a variety of it. Linnæus informs us, that the country-people of Upland in Sweden give an infusion of this lichen in milk to children that are troubled with the disorder called the thrush or aphthæ, which induced that ingenious naturalist to bestow upon it the trivial name of aphthosus. The same writer also tells us, that a decoction of it in water purges upwards and downwards, and will destroy worms.

17. The cocciferus or scarlet-tipped cup-lichen, is frequent in moors and heaths. It has in the first state a granulated crust for its ground, which is afterwards turned into small lacinated leaves, green above, and hoary underneath. The plant assumes a very different aspect, according to the age, situation, and other accidents of its growth; but may be in general readily distinguished by its fructifications, which are fungous tubercles of a fine scarlet colour, placed on the rim of the cup, or on the top of the stalk. These tubercles, steeped in an alkaline lixivium, are said to dye a fine durable red colour.

18. The rangiferinus, or rein-deer lichen, is frequent in woods, heaths, and mountainous places. Its general height, when full-grown, is about two inches. The stalk is hollow, and very much branched from bottom to top: the branches are divided and subdivided, and at last terminated by two, three, four, or five very fine, short, nodding horns. The axillæ of the branches are often perforated. The whole plant is of a hoary white or grey colour, covered with white farinaceous particles, light and brittle when dry, soft and elastic when moist. The fructifications are very minute, round, fuscous, or reddish brown tubercles, which grow on the very extremities of the finest branches; but these tubercles are very seldom found. The plant seems to have no foliaceous ground for the base, nor scarcely any visible roots. Linnæus tells us, that in Lapland this moss grows so luxuriant that it is sometimes found a foot high. There are many varieties of this species, of which the principal is the sylvaticus, or brown-tipt rein-deer lichen. The most remarkable difference between them is, that the sylvaticus turns fuscous by age, while the other always continues white.

19. The plicatus, or officinal stringy lichen, grows on the branches of old trees, but is not very common. The stalks are a foot or more in length, cylindrical, rigid, and string-shaped, very irregularly branched, the branches entangled together, of a cinereous or ash-colour, brittle and stringy if doubled short, otherwise tough and pliant, and hang pendant from the trees on which they grow. The shields grow generally at the extremities of the branches, are nearly flat, or slightly concave, thin, ash-coloured above, pale-brown underneath, and radiated with fine rigid fibres. As the plant grows old, the branches become covered with a white-rough, warty crust; but the young ones are destitute of it. It was formerly used in the shops as an astringent to stop hæmorrhages and to cure ruptures; but is out of the modern practice. Linnæus informs us, that the Laplanders apply it to their feet to relieve the excoriation occasioned by much walking.

20. The barbatus, or bearded lichen, grows upon the branches of old trees in thick woods and pine-forests. The stalks or strings are slightly branched and pendulous, from half a foot to two feet in length, little bigger than a taylor's common sewing-thread; cylindrically jointed towards the base; but surrounded every where else with numerous horizontal capillary fibres, either simple or slightly branched. Their colour is a whitish green. This has an astringent quality like the preceding. When steeped in water, it acquires an orange colour; and, according to Dillenius, is used in Pennsylvania for dyeing that colour.

21. The vulpinus, on gold wiry lichen, grows upon the trunks of old trees, but is not very common. It is produced in erect tufts, from half an inch to two inches in height, of a fine yellow or lemon-colour, which readily discovers it. The filaments which compose it are not cylindrical, but a little compressed and uneven in the surface, variously branched, the angles obtuse, and the branches straggling and entangled one with another. Linnæus informs us, that the inhabitants of Smaland in Sweden dye their yarn of a yellow colour with this lichen, and that the Norwegians destroy wolves by stuffing dead carcases with this moss reduced to powder, and mixed with pounded glass, and so exposing them in the winter season to be devoured by those animals.

LICONIA, in botany: a genus of the digynia order, belonging to the pentandria class of plants. There are five petals inlaid in the pit of the nectarium at its base; the capsule is bilocular and seed-bearing.

LICUALA, a genus of the nat. order of palmæ. The flowers are all hermaphrodite: cal. and cor. three-parted, nect. sertiform drupe. There is one species.

LIEUTENANTS, *Lords, of counties,* are officers who, upon any invasion or rebellion, have power to raise the militia, and to give commissions to colonels and other officers, to arm and form them into regiments, troops, and companies. Under the lords-lieutenants, are deputy-lieutenants, who have the same power; these are chosen by the lords-lieutenants, out of the principal gentlemen of each county, and presented to the king for his approbation.

LIFE ANNUITIES, annual payments, to continue during any given life or lives. The present value of a life annuity is the sum which would be sufficient (allowing for the chance of the life failing) to pay the annuity without loss; and supposing money to bear no interest, the value of an annuity of 1*l.* is equal to the expectation of the life. Thus it will be found by the table given under the article EXPECTATION OF LIFE, that the expectation of a life aged forty, is twenty-three years; or, in other words, that a set of lives at this age, will, one with another, enjoy twenty-three years each of existence, some of them enjoying a duration as much longer as others fall short of it. Therefore, supposing money to bear no interest, 23*l.* in hand for each life would be sufficient to pay to any number of such lives 1*l.* per annum, for their whole duration; or, in other words, 23*l.* is, on this supposition, the value of a life aged forty. But if any improvement is made of money by putting it out to interest, the sum just mentioned will be more than the value, because it will be more than sufficient to pay the annuity; and it will be as much more than sufficient as

the improvement or the interest is greater. If, for instance, money may be so improved by being put out to interest, at 5*l.* per cent. as to double itself in fourteen years, the seller of such an annuity, on putting out *half* the purchase money to interest, will at the end of fourteen years find himself in possession of 20*l.* 10*s.* or of 11*l.* 10*s.* more than is sufficient to pay the remainder of the annuities, though he should make no further improvement of the purchase money. At whatever rate of interest the money is improved, there must be a surplus; and if it is fully improved at 5*l.* per cent., it will be found that 11*l.* 16*s.* 8*d.* for each annuity, will be sufficient (instead of 23*l.*) to make all the annual payments; or, if money can be improved at 6*l.* per cent., 10*l.* 14*s.* 1*d.* will be sufficient.

Many persons have fallen into an error with respect to the value of life-annuities, by considering it the same as the value of an annuity certain for a term of years equal to the expectation of the life. The inaccuracy of this mode of computation arises from the difference between the value of a certain number of payments to be made every year regularly till the term is completed, and the value of the same number of payments to be made at greater distances of time from one another, and not to be all made till many years after the expiration of the term equal to the expectation.

The true method of computing the values of life-annuities cannot be more clearly expressed than as it is given in "The Doctrine of Annuities and Assurance on Lives and Survivorships," by William Morgan.—"Was it *certain* that a person of a given age would live to the end of a year, the value of an annuity of 1*l.* on such a life would be the present sum that would increase in a year to the value of a life one year older, together with the value of the single payment of 1*l.* to be made at the end of a year; that is, it would be 1*l.* together with the value of a life aged one year older than the given life, multiplied by the value of 1*l.* payable at the end of a year. Call the value of a life one year older than the given life N, and the value of 1*l.* payable at the end of a year $\frac{1}{r}$; then will the value of an annuity on the given life, on the supposition of a *certainty*, be $\frac{1}{r} + \frac{1}{r} \times N = \frac{1}{r} \times \overline{1+N}$. But the fact is, that it is *uncertain* whether the given life will exist to the end of the year or not: this last value, therefore, must be diminished in the proportion of this uncertainty; that is, it must be multiplied by the probability that the given life will survive one year, or supposing $\frac{b}{a}$ to express this probability, it will be $\frac{b}{ar} \times \overline{1+N}$. In the same manner the values of annuities on the *joint continuance* of lives may be found: Call the value of any two joint lives M, the probability that two lives one year younger will exist a year $\frac{bd}{ac}$, and $\frac{1}{r}$ as above, the value of 1*l.*, payable at the end of the year. Then, by reasoning as before, the value of the joint continuance of two lives one year younger will be expressed by $\frac{bd}{acr} \times \overline{1+M}$."

By these theorems, tables may be calculated of the values of single or joint lives, according to any table of the probabilities of life, and by the use of logarithms, and computing upwards, from the oldest to the youngest life, the labour of forming such tables is not very great; few persons, however, have occasion to undertake it, as the tables published by Dr. Price, Mr. Morgan and Mr. Maseres, show the values of life annuities as accurately as the present knowledge of the decrements and duration of human life will admit; and are sufficient for almost every useful purpose.

TABLE I.

Showing the Value of an Annuity of 1l. on a Single Life at every age, according to the probabilities of the duration of Human Life at Northampton, reckoning interest at 5 per Cent.

Ages.	Value.	Age.	Value.	Age.	Value.
Birth.	8.863	33	12.740	66	7.034
1 year	11.563	34	12.623	67	6.787
2	13.420	35	12.502	68	6.536
3	14.135	36	12.377	69	6.281
4	14.613	37	12.249	70	6.023
5	14.827	38	12.116	71	5.764
6	15.041	39	11.979	72	5.504
7	15.166	40	11.837	73	5.245
8	15.226	41	11.695	74	4.990
9	15.210	42	11.551	75	4.744
10	15.139	43	11.407	76	4.511
11	15.043	44	11.258	77	4.277
12	14.937	45	11.105	78	4.035
13	14.826	46	10.947	79	3.776
14	14.710	47	10.784	80	3.515
15	14.588	48	10.616	81	3.263
16	14.460	49	10.443	82	3.020
17	14.334	50	10.269	83	2.797
18	14.217	51	10.097	84	2.627
19	14.108	52	9.925	85	2.471
20	14.007	53	9.748	86	2.328
21	13.917	54	9.567	87	2.193
22	13.833	55	9.382	88	2.080
23	13.746	56	9.193	89	1.924
24	13.658	57	8.999	90	1.723
25	13.567	58	8.801	91	1.447
26	13.473	59	8.599	92	1.153
27	18.377	60	8.392	93	0.816
28	13.278	61	8.181	94	0.524
29	13.177	62	7.966	95	0.238
30	13.072	63	7.742	96	0.000
31	12.965	64	7.514		
32	12.854	65	7.276		

These values suppose the payments to be made *yearly*, and to begin at the end of the first year; if the payments are to be made *half-yearly*, the value in the table will be increased about one-fifth of a year's purchase.

In order to find the present value of an annuity during any given life, it is only necessary to multiply the value in the table corresponding with the age, by the given annuity.

Example. What should a person aged 45, give, to purchase an annuity of 50*l.* during his life?

The value in the table against 45 years is 11.105, which multiplied by 50 gives the answer 555*l.* 5*s.*

TABLE II.

Showing the Value of an Annuity during the joint continuance of Two Lives, according to the probabilities of Life at Northampton; reckoning interest at 5 per Cent.

Ages.	Value.	Ages	Value.	Ages.	Value.
5-5	11.984	20-25	10.959	40-45	8.643
5-10	12.315	20-30	10.707	40-50	8.177
5-15	11.954	20-35	10 363	40-55	7.651
5-20	11.561	20-40	9.937	40-60	7.015
5-25	11.281	20-45	9.448	40-65	6.240
5-30	10.959	20-50	8.861	40-70	5.298
5-35	10.572	20-55	8.216	40-75	4.272

It is unnecessary to insert a Table of the values of the longest of two lives, as it may be easily found from the values given in the above tables by the following general rules:

" From the sum of the values of the single lives subtract the value of an annuity on the joint lives, and the remainder will give the value of an annuity on the continuance of the longest of two such lives."

Example. What is the value of an annuity on the longest of two lives whose ages are thirty and forty?

By Table I. the value of a single life of 30 is 13.072, and by the same Table the value of a single life of 40 is 11.837. Their sum therefore is 24.909, from which 9.576 (the value of the joint lives of 30 and 40 by Table II.) being subtracted, gives 15.333 for the number of years purchase required.

The value of an annuity on three joint lives may be found from the preceding tables, by the following rule:

" Let A be the youngest, and C the oldest of the three proposed lives. Take the value of the two joint lives B and C, and find the age of a single life D of the same value. Then find the value of the joint lives A and D, which will be the answer."

Example. Let the three given lives be 20, 30, and 40. The value of the two oldest joint lives B and C will (by Table II.) be 9.576, answering in Table I. to a single life D of 54 years; and the value of the joint lives A and D, or the ages in the Table which come nearest to them, gives 8.216 for the value sought.

The value of three joint lives being known, the value of the longest of any three lives may be computed by the following rule:

" From the sum of the values of all the single lives, subtract the sum of the values of all the joint lives combined two and two. Then to the remainder add the value of the three joint lives; and this last sum will be the value of the longest of the three lives."

Example. The sum of the values of three single lives whose ages are 20, 30, and 40, is (by Table I.) 38.916. The value of two joint lives, whose ages are 20 and 30, is (by Table II.) 10.707; of two joint lives whose ages are 20 and 40, is 9.937, and two joint lives whose ages are 30 and 40 is 9.576; the sum of these three values is 30.220. This sum subtracted from 38.916, leaves 8.696, which remainder added to 8.216 (the value of the three joint lives in the last example), gives 16.912, the value of the longest of the three lives. The answers in this and the preceding example are not quite exact, in consequence of the table of joint lives being confined to the combinations of every fifth year of age; those who have occasion to make such computations, will find more extensive tables of the values of joint lives in Dr. Price's excellent Treatise on Reversionary Payments; but a general table of the values of two joint lives for every possible difference of age, at different rates of interest, has long been very desirable.

The solutions of the following Problems, in addition to the rules already given, will comprehend all the cases which most commonly occur relating to the values of annuities on lives or survivorship.

Prob. I. To determine the value of an annuity on a given life for any number of years.

Solution. Find the value of a life as many years older than the given life as are equal to the term for which the annuity is proposed. Multiply this value by 1*l.*, payable at the end of this term, and also by the probability that the life will continue so long. Subtract the product from the present value of the given life, and the remainder multiplied by the annuity will be the answer.

Example. Let the annuity be 20*l.* the age of the given life 35 years, and the term proposed 14 years. The value

of a life aged 49 years (or 14 years older than the given life), appears by Table I. to be 10,443. The value of 1*l.* payable at the end of 14 years (see COMPOUND INTEREST), is .505068, and the probability that the life will exist so long, (See EXPECTATION of LIFE) is $\frac{2936}{4010}$. These three values multiplied into each other are equal to 3.861, which being subtracted from 12.502 (the present value of the given life by Table I.), we have 8.641, and this remainder multiplied by 20, gives 162*l.* 16*s.* 4*d.* for the value required.

In a similar manner the value of an annuity for any given term, upon two joint lives, may be determined.

PROB. II. To find the value of an annuity certain for a given term after the extinction of any given life or lives.

Solution. Subtract the value of the life or lives from the perpetuity, and reserve the remainder. Then say, as the perpetuity, is to the present value of the annuity certain, so is the said reserved remainder, to a fourth proportional, which will be the number of years purchase required.

Example. A and his heirs are entitled to an annuity certain for 14 years, to commence at the death of B, aged 35. What is the present value of A's interest in this annuity?

By table I. the value of the life of B is 12,502, which subtracted from 20, the perpetuity, leaves 7.498 for the remainder to be reserved. Then, as 20, is to 9.898 (the value of an annuity certain for 14 years), so is 7.498 (the reserved remainder), to 3.7107, the number of years purchase required.

PROB. III. To find the value of an annuity for a term certain, and also for what may happen to remain of a given life or lives after the expiration of this term.

Solution. Find the value of a life or lives as many years older than the given life or lives as are equal to the term for which the annuity certain is proposed. Multiply this value by 1*l.* payable at the end of the given term, and also by the probability that the given life or lives will continue so long. Add the product to the value of the annuity certain for the given term, and the sum will be the answer.

Example. Let the value be required of an annuity certain for 14 years, and also for the remainder of a life now aged 35 after the expiration of this term. By Table I. the value of a life aged 49 (or 14 years older than the given life) is 10.443. The value of 1*l.* payable at the end of 14 years, is .505068, and the probability that the life will exist so long is $\frac{2936}{4010}$. These three numbers multiplied into each other, produce 3.861, which being added to 9.898, the value of an annuity certain for 14 years (see ANNUITIES), becomes equal to 13.759, the number of years purchase required.

PROB. IV. To determine what annuity any given sum will purchase during the joint lives of two persons of given ages, and also during the life of the survivor, on condition that the annuity shall be reduced one-half at the extinction of the joint lives.

Solution. Let twice the given sum be divided by the sum of the two single lives, and the quotient will give the annuity to be paid during the joint lives: one-half of which is therefore the annuity to be paid during the remainder of the surviving life.

Example. A aged 27, and B aged 35, are desirous of sinking 1000*l.* in order to receive an annuity during their joint lives, and also another annuity of half the value during the remainder of the surviving life. It is required to determine what annuities should be granted them under those circumstances. By Table I. the value of a life of 27 is 13.377, and the value of a life of 35 is 12.502. 2000*l.* (or twice the given sum) being divided by 25.879 (the sum of the values of the two lives), gives 77.282*l.* for the annuity to be granted during the joint continuance of the lives; and its half, or 38.641*l.* is the annuity to be paid during the life of the survivor.

PROB. V. B, who is of a given age, will, if he lives till the decease of A, whose age is also given, become possessed of a perpetual annuity, or of an estate of a given yearly value; to find the worth of his expectation in present money.

Solution. Find the value of an annuity on two equal joint lives whose common age is equal to the age of the oldest of the two proposed lives, which value subtract from the perpetuity, and take half the remainder: then say, as the expectation of duration of the younger of the two lives, is to that of the older, so is the said half remainder, to a fourth proportional: which will be the number of years purchase required when the life of B in expectation is the older of the two: but if B be the younger, then add the value so found to that of the joint lives A and B, and let the sum be subtracted from the perpetuity, and you will also have the answer in this case.

Example. Suppose the age of B to be 30, and that of A 20 years, and the value of the estate 50*l.* per annum. Then the value of two equal joint lives, aged 30, is, by Table II. 10.255, and the perpetuity being 20, the difference will be 9.745, the half of which is 4.872. Therefore as 33.43, the expectation of A, is to 28.27, the expectation of B, so is 4.872, to 4.119, which being multiplied by 50, the given annuity, we have 205.95*l.* for the required value of B's expectation.

If the age of B had been 20, and that of A 30 years, then to 4.119, the value just found, add the value of the joint lives, which, by Table II. is 10.707, and the sum is 14.826, which subtracted from 20, the perpetuity, and the remainder multiplied by 50, gives 258.7*l.* for the required value in this case.

LIFE ESTATES are of two kinds, such as are created by the act of the parties, or such as are created by the operation of the law, as estates by curtesy or dower. 2 Black. 120.

Estates for life, created by deed or grant, are, where a lease is made of lands or tenements to a man, to hold for the term of his own life, or for that of another person, or for more lives than one; in any of which cases, he is called tenant for life: only when he holds the estate by the life of another, he is usually termed tenant pur auter vie, for another's life.

Estates for life may be created not only by the express terms before-mentioned, but also by a general grant, without defining or limiting any specific estate. 2 Black. 121.

If such persons, for whose life any estate shall be granted, shall absent themselves seven years, and no proof made of the lives of such persons, in any action commenced for the recovery of such tenements by the

lessors or reversioners, the persons upon whose lives such estate depended, shall be accounted as dead; and the judges shall direct the jury to give their verdict as if the person absenting himself was dead. 19 Car. II. c. 6.

LIGAMENT. See ANATOMY.

LIGATURE. See SURGERY.

LIGHT. See OPTICS.

LIGHTS: stopping lights of any house is a nauisance, for which an action will lie, if the house is an ancient house, and the lights ancient lights: but stopping a prospect is not, being only matter of delight, not of necessity; and a person may have either an assize of nuisance against the persons erecting any such nuisance, or he may stand on his own ground and abate it. 2 Salk. 247.

LIGHTFOOTIA, a genus of the class and order polygamia dioecia. The cal. is four-leaved; cor. none; fem. and her. stigma sessile; berry umbilicated. There are three species, shrubs of the E. Indies.

LIGHTNING. See ELECTRICITY.

LIGUSTICUM, lovage; a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The fruit is oblong, and quinquesulcated on each side; the florets are equal; the petals involuted or rolled inwards, and entire. There are eight species, of which the most remarkable are, the levisticum, or common, and the Scoticum, or Scots, lovage. The first is a native of the Appenine mountains in Italy. The second is a native of Scotland, and grows near the sea in various parts of the country.

The root of the first species agrees nearly in quality with that of angelica: the principal difference is, that the lovage root has a stronger smell, and a somewhat less pungent taste, accompanied with a more durable sweetness, the seeds being rather warmer than the root; but although certainly capable of being applied to useful purposes, this root is not regarded in the present practice. The leaves of the second are sometimes eaten raw as a salad, or boiled as greens, by the inhabitants of the Hebrides. They give an infusion of the leaves in whey to calves. to purge them.

LIGUSTRUM, *privet*, a genus of the monogynia order, in the diandria class of plants; and in the natural method ranking under the 44th order, sepiariæ. The corolla is quadrifid; the berry tetraspermous. There are three species; of the common there are two varieties, the deciduous and the evergreen. They are hardy plants, rising from ten to fifteen feet high. They are easily propagated by seed, layers, suckers, or cuttings. They are used for making hedges. The purple colour upon cards is prepared from the berries. With the addition of alum, these berries are said to dye wool and silk of a good and durable green; for which purpose they must be gathered as soon as they are ripe. The leaves are bitter and slightly astringent. Oxen, goats, and sheep, eat the plant; horses refuse it.

LIKE, in geometry, &c. denotes the same with similar. See SIMILAR.

LILAC, in botany, a genus of trees, otherwise called syringa. See SYRINGA.

LILALITE. This stone appears to have been first observed by the abbe Poda, and to have been then described by De Born. Hitherto it has only been found in Moravia in Germany, and Sudermania in Sweden. There it is mixed with granite in large amorphous masses. It is composed of thin plates, easily separated, and not unlike those of mica. Not easily pulverised. Specific gravity 2.8549. Colour of the mass, violet-blue; of the thin plates, silvery white. Powder white, with a tint of red. Before the blowpipe, it froths, and melts easily into a white semi-transparent enamel, full of bubbles. Dissolves in borax with effervescence, and communicates no colour to it. Effervesces slightly with soda, and melts into a mass spotted with red. With microcosmic salts it gives a pearl-coloured globule.

This stone was first called lilalite from its colour, that of the lily. Klaproth, who discovered its component parts, gave it the name of lepidolite.

It is composed of

53	silica
20	alumina
18	potass
5	fluat of lime
3	oxide of manganese
1	oxide of iron
100.	

LILIUM, the *lily;* a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the 10th order, coronariæ. The corolla is hexapetalous, and campanulated, with a longitudinal nectariferous line or furrow; the capsules connected by small cancellated hairs. There are eleven species; all of them bulbous-rooted, herbaceous, flowery perennials, rising with erect annual stalks three or four feet high, garnished with long narrow leaves, and terminated by fine clusters of large, bell-shaped, hexapetalous flowers of great beauty, of white, red, scarlet, orange, purple, and yellow colours.

All the species are propagated by sowing the seeds; and if care is taken to preserve these seeds from good flowers, very beautiful varieties are often produced.

The roots of the white lily are emollient, maturating, and suppurative, and are used externally in cataplasms for these purposes with success. The common form of applying them is, boiled and bruised. Gerard recommends them internally against dropsies.

The Kamtschatence, or Kamtschatka lily, called there saranne, makes a principal part of the food of Kamtschatkans. Its roots are gathered by the women in August, dried in the sun, and laid up for use: they are the best bread of the country; and after being baked are reduced to powder, and serve instead of flour in soups and several dishes. They are sometimes washed, and eaten as potatoes; are extremely nourishing, and have a pleasant bitter taste. Our navigators boiled and ate them with their meat. The natives often parboil, and beat it up with several sorts of berries, so as to form of it a very agreeable confection. Providentially it is an universal plant there, and all the grounds bloom with its flower during the season. Another happiness remarked there is, that while fish are scarce, the saranne is plentiful; and when there is a dearth of this, the rivers pour in their provisions with redoubled profusion. It is not to the labours of the females alone that the Kamtschatkans

are indebted for these roots. A species of mouse saves them a great deal of trouble. The saranne forms part of the winter provisions of that little animal: they not only gather them in the proper season, and lay them up in their magazines, but at times have the instinct of bringing them out in sunny weather to dry them, lest they should decay. The natives search for their hoards; but with prudent tenderness leave part for the owners, being unwilling to suffer such useful caterers to perish.

LIMAX, the *slug*, or naked snail; a genus of insects belonging to the order of vermes mollusca. The body is oblong, fitted for crawling, with a kind of muscular coat on the upper part, and the belly is plain. They have four tentacula, or horns, situated above the mouth, which they extend or retract at pleasure. This reptile is always destitute of shell; but besides that its skin is more clammy, and of a greater consistency, than that of the snail, the black naked slug has a furrowed cloak, almost as thick and as hard as leather, under which it withdraws its head as within a shell. The head is distinguished from the breast by a black line. It is in its head and back that the snail-stone is found; which is a small pearled and sandy stone, of the nature of limestones: according to a popular opinion, it cures the tertian ague, if fastened to the patient's arm. These slugs move on slowly, leaving every where clammy and shining marks of their passage. They deposit their eggs in the earth. There are eight species, distinguished entirely by their colour; as the black slug, the white slug, the reddish slug, the ash-coloured slug, &c. The black slug is hermaphrodite. A black slug, powdered over with snuff, salt, or sugar, falls into convulsions, casts forth all its foam, and dies.

LIME, one of those earthy substances, which exist in every part of the known world. It is found purest in limestone, marble, and chalk. None of these substances are lime, but are capable of becoming so by burning in a white heat.

Lime may be also obtained perfectly pure by burning those crystallized limestones called calcareous spars, which are perfectly white and transparent, and also by burning some pure white marbles. It may be procured also in a state of purity by dissolving oyster-shells in muriatic acid, filtring the solution, mixing it with ammonia as long as a white powder continues to fall, and filtring again. The liquid is now to be mixed with a solution of carbonat of soda: the powder which falls being washed and dried, and heated violently in a platinum crucible, is pure lime.

Pure lime is of a white colour, moderately hard, but easily reduced to a powder. It has a hot burning taste, and in some measure corrodes and destroys the texture of those animal bodies to which it is applied. Its specific gravity is 2.3. It tinges vegetable blues green, and at last converts them to yellow.

If water be poured on newly burnt lime, it swells and falls to pieces, and is soon reduced to a very fine powder. In the mean time so much heat is produced, that part of the water flies off in vapour. If the quantity of lime slacked (as this process is termed) be great, the heat produced is sufficient to set fire to combustibles. In this manner, vessels loaded with lime have sometimes been burnt. When great quantities of lime are slacked in a dark place, not only heat but light also is emitted, as Mr. Pelletier has observed. When slacked lime is weighed, it is found to be heavier than it was before. This additional weight is owing to the combination of part of the water with the lime; which water may be separated again by the application of a red heat; and by this process the lime becomes just what it was before being slacked. Hence the reason of the heat evolved during the slacking of lime. Part of the water combines with the lime, and thus becomes solid; of course it parts with its caloric of fluidity, and probably also with a considerable quantity of caloric, which exists in water even when in the state of ice: for when two parts of lime and one part of ice (each at 32°) are mixed, they combine rapidly, and their temperature is elevated to 212°. The elevation of temperature during the slacking of barytes and strontian is owing to the same cause.

The smell perceived during the slacking of lime is owing to a part of that earth being elevated along with the vapour of the water; as evidently appears from this circumstance, that vegetable blues exposed to this vapour are converted to green.

Limestone and chalk, though they are capable of being converted into lime by burning, posesses hardly any of the properties of that active substance. They are tasteless, scarcely soluble in water, and do not perceptibly act on animal bodies. Now, to what are the new properties of lime owing? What alteration does it undergo in the fire?

It had been long known, that limestone loses a good deal of weight by being burned or calcined. It was natural to suppose, therefore, that something is separated from it during calcination. Dr. Black, of Edinburgh, published in 1756, those celebrated experiments on this subject, which form so brilliant an era in the history of chemistry. He first ascertained, that the quantity of water separated from limestone during its calcination is not nearly equal to the weight which it lost. He concluded in consequence, that it must have lost something else than mere water. What this could be, he was at first at a loss to conceive; but recollecting that Dr. Hales had proved, that limestone, during its solution in acids, emits a great quantity of air, he conjectured that this might probably be what it lost during calcination. He calcined it accordingly, and applied a pneumatic apparatus to receive the product. He found his conjecture verified; and that the air and water which separated from the lime were together precisely equal to the loss of weight which it had sustained. Lime, therefore, owes its new properties to the loss of air; and limestone differs from lime merely in being combined with a certain quantity of air: for he found that, by restoring again the same quantity of air to lime, it was converted into limestone. This air, because it existed in lime in a fixed state, he called fixed air. It was afterwards examined by Dr. Priestley and other philosophers; found to possess peculiar properties, and to be that species of gas now known by the name of carbonic acid gas. Lime then is a simple substance, and limestone is composed of carbonic acid and lime. Heat separates the carbonic acid, and leaves the lime in a state of purity. See Air.

When lime is exposed to the open air, it gradually attracts moisture, and falls to powder; after which it soon

becomes saturated with carbonic acid, and is again converted into carbonat of lime or unburnt limestone.

Water, at the common temperature of the atmosphere, dissolves about 0.002 parts of its weight of lime. This solution is called lime-water. It is limpid, has an acrid taste, and changes vegetable blue colours to green. One ounce tr y of lime-water contains about one grain of lime. It is usually formed by throwing a quantity of lime in powder into pure water, allowing it to remain for some time in a close vessel, and then decanting the transparent solution from the undissolved lime. When lime-water is exposed to the air, a stony crust soon forms on its surface, composed of carbonat of lime; when this crust is broken it falls to the bottom and another succeeds it; and in this manner the whole of the lime is soon precipitated, by absorbing carbonic acid from the air.

Lime is not acted on by light, neither does it combine with oxygen. Sulphur and phosphorus are the only simple combustibles with which it unites.

Sulphuret of lime may be formed by mixing its two component parts, reduced to a powder, and heating them in a crucible. They undergo a commencement of fusion, and form an acrid taste. When it is exposed to the air, or moistened with water, its colour becoming greenish yellow, sulphureted hydrogen is formed, and the sulphuret is converted into a hydrogenated sulphuret, which exhales a very fetid odour of sulphureted hydrogen gas. This hydrogenated sulphuret may be formed also by boiling a mixture of lime and sulphur in about ten times its weight of water, or by sprinkling quicklime with sulphur and then moistening it: the heat occasioned by the slacking of the lime is sufficient to form the combination. When this hydrogenated sulphuret is exposed to the air, it imbibes oxygen; which combines at first with the hydrogen, and afterwards with the sulphur, and converts the compound into sulphat of lime.

Phosphuret of lime may be formed by the following process: put into the bottom of a glass tube, close at one end, one part of phosphorus; and, holding the tube horizontally, introduce five parts of lime in small lumps, so that they shall be about two inches above the phosphorus. Then place the tube horizontally among burning coals, so that the part of it which contains the lime may be made red-hot, while the bottom of the tube containing the phosphorus remains cold. When the lime becomes red-hot, raise the tube, and draw it along the coals till that part of it which contains the phosphorus is exposed to a red heat. The phosphorus is immediately volatilized, and passing through the hot lime combines with it. During the combination the mass becomes of a glowing red heat, and a quantity of phosphureted hydrogen gas is emitted, which takes fire when it comes into the air.

Lime does not combine with azote; but it unites readily with muriatic acid, and forms muriate of lime. It facilitates the oxidizement of several of the metals, and it combines with several of the metallic oxides, and forms salts which have not hitherto been examined, if we except the compounds which it forms with the oxides of mercury and lead, which have been described by Berthollet.

The red oxide of mercury, boiled with lime-water, is partly dissolved, and the solution yields by evaporation small transparent yellow crystals. This compound has been called by some mercuriat of lime.

Lime-water also dissolves the red oxide of lead, and (still better) litharge. This solution, evaporated in a retort, gives very small transparent crystals, forming prismatic colours, and not more soluble in water than lime. It is decomposed by all the alkaline sulphats, and by sulphureted hydrogen gas. The sulphuric and muriatic acids precipitate the lead. This compound blackens wool, the nails, the hair, and white of eggs; but it does not affect the colour of silk, the skin, the yolk of egg, nor animal oil. It is the lead which is precipitated on these coloured substances in the state of oxide; for all acids can dissolve it. The simple mixture of lime and oxide of lead blackens these substances; a proof that the salt is easily formed.

Lime does not combine with alkalies. The affinities of lime are arranged by Bergman in the following order:

Oxalic acid	Arsenic
Sulphuric	Lactic
Tartaric	Citric
Succinic	Benzoic
Phosphoric	Sulphurous
Saclactic	Acetic
Nitric	Boracic
Muriatic	Carbonic
Suberic	Prussic
Fluoric	

One of the most important uses of lime is, in the formation of mortar as a cement in building. Mortar is composed of quicklime and sand reduced to a paste with water. When dry it becomes as hard as stone, and as durable; and adhering very strongly to the surfaces of the stones which it is employed to cement, the whole wall becomes in fact nothing else than one single stone. But this effect is produced very imperfectly unless the mortar is very well prepared.

The lime ought to be pure, completely free from carbonic acid, and in the state of a very fine powder: the sand should be free from clay, and partly in the state of fine sand, partly in that of gravel: the water should be pure; and if previously saturated with lime, so much the better. The best proportions, according to the experiments of Dr. Higgins, are three parts of fine sand, four parts of coarse sand, one part of quicklime recently slacked, and as little water as possible.

The stony consistence which mortar acquires, is owing partly to the absorption of carbonic acid, but principally to the combination of part of the water with the lime. This last circumstance is the reason that if to common mortar one-fourth part of lime, reduced to powder without being slacked, is added, the mortar, when dry, acquires much greater solidity than it otherwise would do. This was first proposed by Loriot; and a number of experiments were afterwards made by Morveau. The proportions which this philosopher found to answer best are the following:

Fine sand - - -	0.3
Cement of well-baked bricks	0.3
Slacked lime - - -	0.2
Unslacked lime - -	0.2
	1.0

The same advantages may be attained by using as little water as possible in slacking the lime.

Higgins found that the addition of burnt bones improved mortar by giving it tenacity, and rendering it less apt to crack in drying; but they ought never to exceed one-fourth of the lime employed.

When a little manganese is added to mortar, it acquires the important property of hardening under water; so that it may be employed in constructing those edifices which are constantly exposed to the action of water. Limestone is often combined with manganese: in that case it becomes brown by calcination.

LIMESTONE. See SALTS, *calcareous*.

LIMESTONE, *primitive* and *secondary*. See ROCKS.

LIMEUM, a genus of the class and order heptandria digynia. The cal. is five-leaved; pet. five; caps globular, two-celled. There are three species, herbaceous plants of the Cape.

LIMIT, in a restrained sense, is used by mathematicians for a determinate quantity to which a variable one continually approaches; in which sense the circle may be said to be the limit of its circumscribed and inscribed polygons. In algebra, the term limits is applied to two quantities, one of which is greater, and the other less, than another quantity; and in this sense it is used in speaking of the limits of equations, whereby their solution is much facilitated.

Let any equation, as $x^3 - px^2 \times qx - r = 0$ be proposed; and transform it into the following equation:

$$\left.\begin{array}{l} y^3 + 3ey^2 + 3ey^2 + e^3 \\ py - py^2 - 2pey - pe^2 \\ \quad + qy + qe \\ \quad\quad - r \end{array}\right\} = 0,$$

where the values of y are less than the respective values of x, by the difference e. If you suppose e to be taken such as to make all the co-efficients of the equation of y positive, viz. $e^3 - pe^2 + qe - r$, $3e^2 - 2pe + q$, $3e - p$; then there being no variation of the signs in the equation, all the values of y must be negative; and consequently the quantity e, by which the values of x are diminished, must be greater than the greatest positive value of x: and, consequently, must be the limit of the roots of the equation $x^3 - px^2 + qx - r = 0$.

It is sufficient, therefore, in order to find the limit, to inquire what quantity substituted for x, in each of these expressions $x^3 - px^2 + qx - r$, $3x^2 - 2px + q$, $3x - p$, will give them all positive; for the quantity will be the limit required.

Having found the limit that surpasses the greatest positive root, call it m. And if you assume $y = m - x$, and for x substitute $m - y$, the equation that will arise will have all its roots positive; because m is supposed to surpass all the values of x, and consequently $m - x$ $(= y)$ must always be affirmative. And by this means, any equation may be changed into one that shall have all its roots affirmative.

Or, if $-n$ represent the limit of the negative roots, then by assuming $y - x + n$, the proposed equation shall be transformed into one that shall have all its roots affirmative; for, $+ n$ being greater than any negative value of x, it follows that $y = x - n$ must be always positive.

What is here said of the above cubic equation, may be easily applied to others; and of all such equations, two limits are easily discovered, viz. o, which is less than the least; and e, found as above, which surpasses the greatest root of the equation. But besides these, other limits still nearer the roots may be found: for the method of doing which, the reader may consult Maclaurin's Algebra.

LIMITATION, a certain time prescribed by statute, within which an action must be brought. The time of limitation is twofold; first in writs, by divers acts of parliament; secondly, to make a title to any inheritance, and that is by the common law.

Limitation on penal statutes.—All actions, suits, bills, indictments, or informations, which shall be brought for any forfeiture upon any statute penal, made or to be made, whereby the forfeiture is or shall be limited to the queen, her heirs or successors only, shall be brought within two years after the offence committed, and not after two years; and all actions, suits, bills, or informations, which shall be brought for any forfeiture upon any penal statute, made or to be made, except the statutes of tillage, the benefit and suit whereof is or shall be by the said statute limited to the queen, her heirs or successors, and to any other that shall prosecute in that behalf, shall be brought by any person that may lawfully sue for the same, within one year next after the offence committed; and in default of such pursuit, then the same shall be brought for the queen's majesty, her heirs or successors, any time within the two years, after that year is ended; and it is provided, that where a shorter time is limited by any penal statute, the prosecution must be within that time. 31 Eliz. c. 5.

Limitation in regard to personal actions of assault and battery, and actions arising upon contract and trespass.

All actions of trespass, of assault, battery, wounding, imprisonment, or any of them, shall be commenced and sued within four years next after the cause of such actions or suits, and not after. 21 Jac. I. c. 16.

Actions of account, &c.—All actions of trespass quare clausum fregit, all actions of trespass, detinue, trover, and replevin, all actions of account, and upon the case (other than such accounts as concern the trade of merchandize, between merchant and merchant), all actions of debt grounded upon any lending, or contract without specialty, (that is, not being by deed or under seal) all actions of debt for arrearages of rent, and all actions of assault, menace, battery, wounding, and imprisonment, shall be commenced within the time and limitation as followeth, and not after; that is to say, the said actions upon the case (other than for slander), and the said actions for trespass, debt, detinue, and replevin, and the said acts for trespass quare clausum fregit, within six years, after the cause of such action. 21 Jac. c. 16.

Exception in relation to infants.—It has been holden, that if an infant during his infancy, by his guardian bring an action, the defendant cannot plead the statute of limitation, although the cause of action accrued six years before; and the words of the statute are, that after his coming of age, &c.

Exception in relation to merchants' accounts.—As to this exception, it has been matter of much controversy,

whether it extends to all actions and accounts relating to merchants and merchandize, or to actions of account open and current only. But it is now settled, that accounts open and current only are within the statute; and that therefore, if an account be stated and settled between merchant and merchant, and a sum certain agreed to be due to one of them, if in such case, he to whom the money is due, do not bring his action within the limited time, he is barred by the statute. 2 Mod. 312.

Exception in relation to persons beyond sea.—It seems to have been agreed that the exception as to persons being beyond sea, extends only where the creditors or plaintiffs are so absent, and not to debtors or defendants, because the first only are mentioned in the statute; and this construction has the rather prevailed, because it was reputed the creditor's folly, that he did not file an original, and outlaw the debtor, which would have prevented the bar of the statutes.

Executor or administrator.—If A receives money belonging to a person who afterwards died intestate, and to whom B takes out administration, and brings an action against A, to which he pleads the statute of limitations, and the plaintiff replies, and shows that administration was committed to him such a year, which was within six years; though six years are expired since the receipt of the money, yet not being so since the administration committed, the action is not barred by the statute. 1 Salk. 421.

Where a debt barred by the statute shall be revived.—Any acknowledgment of the existence of the debt, however slight, will take it out of the statute, and the limitation will then run from that time: and where an expression is ambiguous, it shall be left to the consideration of the jury, whether it amounts or not to such acknowledgment. 2 Durnf. & East, 760.

It is clearly agreed, that if after the six years, the debtor acknowledges the debt, and promise payment, that this revives it, and brings it out of the statute: as if a debtor by promissory note, or simple contract, promises within six years of the action brought, that he will pay the debt; though this was barred by the statute, yet it is revived by the promise; for as the note itself was at first but an evidence of the debt, so that being barred the acknowledgment and promise is a new evidence of the debt, and being proved, will maintain an assumpsit for recovery of it. 1 Salk. 28.

Limits of a planet, its greatest excursion from the ecliptic, or which is the same thing, the points of its greatest latitude.

LIMITED problem, a problem that admits but of one solution, as to make a circle pass through three given points, not lying in the same right line.

LIMOSELLA, a genus of the didynamia angiospermia class of plants: the flower consists of one erect petal, divided into five segments; fruit is an unilocular capsule, with a great many seeds. Two species, annuals of the Cape.

LIMODORUM, a genus of the gynandria diandria class of plants, the flower of which consists of five oblong petals, and the nectarium hollow, and formed of a single leaf: the fruit is a columnar unilocular capsule, containing a great number of very small seeds. There are thirteen species, bulbs of America, &c.

LIMONIA, a genus of the decandria monogynia class and order. The cal. is five-parted; pet. five-berry, three-celled. Seeds solitary. There are seven species, trees of the East Indies, &c.

LINCONIA, a genus of the class and order pentandria digynia. The pet. are five; caps. two-celled. There is one species, a shrub of the Cape.

LINDERA, a genus of the class and order hexandria monogynia. The cor. is six-petalled; caps. two-celled. There is one species, a shrub of Japan.

LINDERNIA, a genus of the class and order didynamia angiospermia. The cal. is five-parted; caps. one-celled. There are three species, annuals of America.

LINE, in geometry, a quantity extended in length only, without any breadth or thickness. It is formed by the flux or motion of a point: see Fluxion, and Geometry. Right lines are all of the same species, but curves are of an infinite number of different species. We may conceive as many as there may be different ratios between their ordinates and abscisses.

Curve lines are usually divided into geometrical and mechanical; the former are those which may be found exactly in all their points; the latter are those, some or all of whose points are not to be found precisely, but only tentatively, or nearly.

Curve lines are also divided into the first order, second order, third order, &c. See Curve.

Lines considered as to their positions, are either parallel, perpendicular, or oblique, the construction and properties whereof see under Parallel, &c.

Euclid's second book treats mostly of lines, and of the effects of their being divided and again multiplied into one another.

Lines, in perspective, are, 1. Geometrical line, which is a right line drawn in any manner on the geometrical plane. 2. Terrestrial line, or fundamental line, is a right line wherein the geometrical plane, and that of the picture or draught, intersect one another. See Perspective.

Lines. See Dialling.

Line of direction on the earth's axis, in the Pythagorean system of astronomy, the line connecting the two poles of the ecliptic and of the equator, when they are projected on the plane of the former.

Line of direction. See Mechanics.

Line of gravitation of any heavy body, a line drawn through its centre of gravity, and according to which it tends downwards.

Line of the swiftest descent of a heavy body, is the cycloid. See Cycloid.

Lines on the plain scale, are the line of chords, line of sines, line of tangents, line of secants, line of semitangents, line of leagues; the construction and application of which see under the words Scale, Sailing, Instruments, &c.

Lines on Gunter's scale. See Gunter's Scale.

Lines of the sector. See Instruments.

Lines, in fortification, are those of approach, capital defence, circumvallation, contravallation of the base, &c.

To Line a work, signifies to strengthen a rampart with a firm wall; or to encompass a parapet or moat with good turf, &c.

Line, in the art of war, is understood of the disposition of an army, ranged in order of battle, with the front extended as far as may be, that it may not be flanked.

Line of battle, is also understood of the disposition of a fleet on the day of engagement.

Ship of the Line, a vessel large enough to be drawn up in the line, and to have a place in a sea-fight.

Line, also denotes a French measure, containing the twelfth part of an inch, or the hundred and forty-fourth part of a foot. Geometricians conceive the line subdivided into six points. The French line answers to the English barleycorn.

LINEAR numbers, in mathematics, such as have relation to length only; such is a number which represents one side of a plane figure. If the plane figure be a square, the linear number is called a root.

Linear problem, that which may be solved geometrically, by the intersection of two right lines. This is called a simple problem, and is capable but of one solution.

LINEN, in commerce, a well-known kind of cloth, chiefly made of flax. See Linum, and Weaving.

LING. See Gadus.

LINIMENT. See Pharmacy.

LINNÆA, a genus of the class and order didynamia angiospermia. The cal. is double; the cor. bell-shaped; the berry dry, three-celled. There is one species, a herb of Sweden.

LINNET. See Fringillia.

LINSEED, the seed of the plant linum. See Linum.

LINSPINS, in the military art, small pins of iron, which keep the wheel of a cannon or waggon on the axletree; for when the end of the axle-tree is put through the nave, the linspin is put in, to keep the wheel from falling off.

LINT, the scrapings of linen; which is used in dressing wounds, and is made up in various forms, as tents, dossils, pledgets, &c. See Surgery.

LINUM, flax; a genus of the pentagynia order, in the pentandria class of plants; and in the natural method ranking under the 14th order, gruinales. The calyx is pentaphyllous; the petals are five; the capsule is quinquevalved and decemlocular; and the seeds are solitary. There are 25 species, of which the most remarkable are,

1. The usitatissimum, or common annual flax. 2. The perenne, or perennial Siberian flax, with umbellate clusters of large blue flowers. 3. The catharticum, or purging flax, a very small plant, not above four or five inches high; found wild upon chalky hills and in dry pleasure-grounds.

The first species is cultivated in the fields for the use of the manufactures. The second sort is chiefly ornamental. The virtue of the third species is expressed in its title: an infusion in water or whey of a handful of the fresh leaves, or a dram of them in substance when dried, is said to purge without inconvenience.

Of the cultivation of flax. A skilful flax-raiser always prefers a free, open, deep loam; and all grounds that produced the preceding year a good crop of turnips, cabbages, potatoes, barley, or broad clover; or have been formerly laid down rich, and kept for some years in pasture.

If the linseed is sown early, and the flax not allowed to stand for seed, a crop of turnips may be got after the flax that very year; the second year a crop of rye or barley may be taken; and the third year, grass-seeds are sometimes sown along with the linseed. Of preceding crops, potatoes and hemp are the best preparation for flax. If the ground is free and open, it should be but once ploughed, and that as shallow as possible, not deeper than two and a half inches. It should be laid flat, reduced to a fine garden mould by good harrowing, and all stones and sods should be carried off. Except a little pigeon's dung for cold or sour ground, no other dung should be used preparatory for flax; because it produces too many weeds, and throws up the flax thin and poor upon the stalk. Before sowing, the bulky clods should be broken, or carried off the ground; and stones, quickenings, and every other thing that may hinder the growth of the flax, should be carefully taken away. The brighter in colour, and heavier the seed is, so much the better; that which when bruised appears of a light or yellowish green, and fresh in the heart, oily, and not dry, and smells and tastes sweet, and not fusty, may be depended upon. Dutch seed of the preceding year's growth, for the most part, answers best; but it seldom succeeds if kept another year. It ripens sooner than any other foreign seed. Philadelphia seed produces fine lint and few bools, because sown thick, and answers best in wet cold soils.

The quantity of linseed sown should be proportioned to the condition of the soil; for if the ground is in good heart, and the seed sown thick, the crop will be in danger of falling before it is ready for pulling. The time for sowing linseed is from the middle of March to the end of April, as the ground and season answer; but the earlier the seed is sown, the less the crop interferes with the corn harvest. Late sown linseed may grow long, but the flax upon the stalk will be thin and poor.

Flax ought to be weeded, when the crop is about four inches long. If longer deferred, the weeders will also much break and bend the stalks, and they will perhaps never recover their straightness again; and when the flax grows crooked, it is more liable to be hurt in the rippling and swingling. Quicken grass should be taken up; for, being strongly rooted, the pulling of it always loosens a great deal of the lint. If there is an appearance of a settled drought, it is better to defer the weeding, than by that operation to expose the tender roots of the flax to the drought.

When the crop grows so short and branchy as to appear more seed than flax, it ought not be pulled before it is thoroughly ripe; but if it grows long and not branchy, the seed should be disregarded, and all the attention given to the flax. In the last case it ought to be pulled after the bloom has fallen, when the stalk begins to turn yellow, and before the leaves fall, and the bolls turn hard and sharp-pointed. When the stalk is small, and carries few bolls, the flax is fine; but the stalk of coarse flax is gross, rank, branchy, and carries many bolls. When the flax has fallen, and lies, such as lies ought to be immediately pulled, whether it has grown enough or not, as otherwise it will rot altogether. When parts of the same field grow unequally, so that some parts are ready for pulling before other parts, only what is ready should be pulled, and the rest should be suffered to stand till it ripens. The flax-raiser ought to be at pains to pull and keep by itself, each different kind of lint which he finds

in his field; what is both long and fine, by itself; what is both long and coarse, by itself; what is both short and fine, by itself; what is both short and coarse by itself; and in like manner every other kind by itself that is of the same size and quality.

If the flax is more valuable than the seed, it ought by no means to be stacked up; for its own natural juice assists it greatly in the watering; whereas, if kept long unwatered, it loses that juice, and the harle adheres so much to the boon, that it requires longer time to water, and even the quality of the flax becomes harsher and coarser. Besides, the flax stacked up is in great danger from vermin and other accidents; the water in spring is not so soft and warm as in harvest; and near a year is lost of the use of the lint; but if the flax is so short and branchy as to appear most valuable for seed, it ought, after pulling, to be stacked and dried upon the field, as is done with corn; then stacked up for winter, rippled in spring; and the seed should be well cleaned from bad seeds, &c

If the flax is to be regarded more than the seed, it should, after pulling, be allowed to lie some hours upon the ground to dry a little, and so gain some firmness, to prevent the skin or harle, which is the flax, from rubbing off in the rippling; an operation which ought by no means to be neglected, as the bolls, if put into the water along with the flax, breed vermin there, and otherwise spoil the water. The bools also prove very inconvenient in the grassing and breaking. The handfuls for rippling should not be great, as that endangers the lint in the rippling comb. After rippling, the flax-raiser will perceive, that he is able to assort each size and quality of the flax by itself more exactly than he could before.

In watering, a running stream wastes the lint, makes it white, and frequently carries it away. Lochs, by the great quantity and motion of the water, also waste and whiten the flax, though not so much as running streams. Both rivers and lochs water the flax quicker than canals. The greater way the river or brook has run, the softer, and therefore the better, will the water be. Springs, or short runs from hills, are too cold, unless the water is allowed to stand long in the canal. Water from coal or iron is very bad for flax. A little of the powder of galls thrown into a glass of water will discover if it comes from minerals of that kind, by turning it into a dark colour, more or less tinged in proportion to the quantity of metal it contains. When the water is brought to a proper heat, small plants will be rising quickly in it, numbers of small insects and reptiles will be generating there, and bubbles of air rising on the surface. If no such signs appear, the water is scarcely warm enough, or is otherwise unfit for flax. Moss-holes, when neither too deep nor too shallow, frequently answer well for watering flax, when the water is proper, as before described. The proper season for watering flax is from the end of July to the end of August. The doing this as soon as possible after pulling is very advantageous. The flax being sorted after rippling, as before mentioned, should next be put in beets, never larger than a man can grasp with both his hands, and tied very slack with a band of a few stalks. Dried rushes answer exceedingly well for binding flax, as they do not rot in the water, and may be dried and kept for use again. The beets should be put into the canals slope-ways, or half-standing upon end, the root end uppermost. Upon the crop ends, when uppermost, vermin frequently breed, destructive of the flax, which are effectually prevented by putting the crop end downmost. The whole flax in the canal ought to be carefully covered from the sun with divots; the grassy side of which should be next the flax, to keep it clean. If it is not thus covered, the sun will discolour the flax, though quite covered with water. If the divots are not weighty enough to keep the flax entirely under water, a few stones might be laid above them; but the flax should not be pressed to the bottom.

When the flax is sufficiently watered, it feels soft to the gripe, and the harle parts easily with the boon or show, which last is then become brittle, and looks whitish. When these signs are found, the flax should be taken out of the water, beet after beet; each gently rinsed in the water, to cleanse it of the filth which has gathered about it in the canal; and as the lint is then very tender, and the beet slackly tied, it must be carefully and gently handled. Great care ought to be taken that no part be overdone: and as the coarsest waters soonest, if different kinds are mixed together, a part will be rotted, when the rest is not sufficiently watered. When lint taken out of the canal is not found sufficiently watered, it may be laid in a heap for twelve, eighteen, or twenty-four hours, which will have an effect like more watering; but this operation is nice, and may prove dangerous in unskilful hands. After the flax is taken out of the canal, fresh lint should not be put a second time into it, until the former water is run off, and the canal cleaned, and supplied with a fresh quantity of water.

Short heath is the best field for grassing flax; as, when wet, it fastens to the heath, and is thereby prevented from being blown away by the wind. The heath also keeps it a little above the earth, and so exposes it more equally to the weather. When such heath is not to be got, links or clean old lea-ground is the next best. Long-grass grounds should be avoided, as the grass growing through the lint frequently spots, tenders, or rots it; and grounds exposed to violent winds should also be avoided. The flax, when taken out of the water, must be spread very thin upon the ground; and being then very tender, it must be gently handled. The thinner it is spread the better, as it is then more equally exposed to the weather. But it ought never to be spread during a heavy shower, as that would wash and waste the harle too much, which is then excessively tender, but soon after becomes firm enough to bear the rains, which, with the open air and sunshine, cleans, softens, and purifies the harle to the degree wanted, and makes it blister from the boon. In short, after the flax has got a little firmness by being a few hours spread in dry weather, the more rain and sunshine it gets the better. If there is little danger of high winds carrying off the flax, it will be much the better for being turned about once a week. If it is not to be turned, it ought to be very thin spread. The spreading of flax and hemp, which requires a great deal of ground, enriches it greatly. The flax-raiser should spread his first row of flax at the end of the field opposite to the point whence the most violent wind commonly comes, placing the root ends foremost. He makes the root ends of every other row overlap the crop ends of the former row three or four inches, and binds down the last row with a rope;

by which means the wind does not easily get below the lint to blow it away; and as the crop ends are seldom so fully watered as the root ends, the overlapping has an effect like giving the crop ends more watering.

A dry day ought to be chosen for taking up the flax; and if there is no appearance of high wind, it should be loosed from the heath or grass, and left loose for some hours, to make it thoroughly dry.

As a great quantity of flax can scarcely be all equally watered and grassed, and as the different qualities will best appear at lifting the flax off the grass; therefore at that time each different kind should be gathered together, and kept by itself; that is, all of the same colour, length, and quality.

The smaller the beets lint is made up in, the better for drying, and the more convenient for stacking, housing, &c. and in making up these beets, as in every other operation upon flax, it is of great consequence that the lint be laid together as it grew, the root ends together, and the crop ends together. The profit on five acres of flax raised in Shropshire, was 46*l.* 4*s.* 5*d.*

LION. See Felis.

LIPARIA, a genus of the diadelphia decandria class and order. The cal. is five-cleft; cor. wings two-lobed, below; stam. the larger, with three shorter teeth; legume ovate. There are four species, shrubs of the Cape.

LIPPIA, a genus of the didynamia gymnospermia class and order. The cal. is four-toothed; the caps. one-celled, three-valved, two-seeded; seed one, two-celled. There are five species, shrubs of America.

LIQUEFACTION. See Fluidity.

LIQUIDS, expansion of. See Expansion.

LIQUIDAMBAR, Sweet-gum tree, a genus of the polyandria order, in the monœcia class of plants; and in the natural method ranking with those of which the order is doubtful. The male calyx is common and triphyllous; there is no corolla, but numerous filaments; the male calyces are collected into a spherical form, and tetraphyllous; there is no corolla; but seven styles, and many bivalved and monospermous capsules, collected into a sphere. There are only two species, both deciduous, viz. 1. The styraciflua, or the Virginia or maple-leaved liquidambar; a native of the rich moist parts of Virginia and Mexico. It will shoot in a regular manner to thirty or forty feet high, having its young twigs covered with a smooth light-brown bark, while those of the older are of a darker colour. The flowers are of a kind of saffron-colour: they are produced at the ends of the branches the beginning of April, and sometimes sooner; and are succeeded by large round brown fruit, which looks singular, but is thought by many to be no ornament to the tree. 2. The peregrinum, Canada liquidambar, or spleenwort-leaved gale, is a native of Canada and Pennsylvania. The young branches of this species are slender, tough, and hardy. The flowers come out from the sides of the branches, like the former; and they are succeeded by small roundish fruit, which seldom ripens in England. These may be propagated either by seeds or layers.

The leaves of this tree emit their odoriferous particles in such plenty as to perfume the circumambient air; nay, the whole tree exudes such a fragrant transparent resin, as to have given occasion to its being taken for the sweet storax. (See Styrax.) These trees, therefore, are very proper to be planted singly in large opens, that they may amply display their fine pyramidal growth, or to be set in places near seats, pavilions, &c. The resin was formerly of great use as a perfume, and is at present no stranger in the shops.

LIQUORICE. See Glycirrhiza, and Materia Medica.

LIRIODENDRON, the Tulip-tree, a genus of the polygynia order, in the polyandria class of plants; and in the natural method ranking under the 52d order, coadunatæ. The calyx is triphyllous; there are nine petals; and the seeds imbricated in such a manner as to form a cone. There are two species; the tulipfera, is best known here, and is a deciduous tree, native of most part of America. It rises with a large upright trunk, branching forty or fifty feet high. The trunk, which often attains to a circumference of thirty feet, is covered with a grey bark. The leaves grow irregularly on the branches, on long footstalks. They are of a particular structure, being composed of three lobes, the middlemost of which is shortened in such a manner that it appears as if it had been cut off and hollowed at the middle. The two others are rounded off. They are about four or five inches long, and as many broad. The flowers are produced with us in July, at the ends of the branches. The number of petals of which each is composed, like those of the tulip, is six; and these are spotted with green, red, white, and yellow. The flowers are succeeded by large cones, which never ripen in England.

LISIANTHUS, a genus of the pentandria monogynia class and order. The cal. is keeled; cor. with ventricose tube and recurved division; stigma two-plated; caps. two-valved, two-celled. There are nine species, herbs of the West Indies.

LITA, a genus of the class and order pentandria monogynia. The cal. is five-cleft; cor. salver-shaped, long tube, five-cleft; caps. one-celled, two-valved; seeds numerous. There are two species, herbs of Guiana.

LITHOPHILA, a genus of the diandria monogynia class and order. The cal. is three leaved; cor. three-petalled; nect. two-leaved. There is one species, of no note.

LITHARGE, an oxide of lead. See Lead.

LITHOPHYTA, the name of Linnæus's third order of vermes.

LITHOSPERMUM, gromwell: a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 41st order, asperifoliæ. The corolla is funnel-shaped, with the throat perforated and naked; the calyx quinquepartite. There are 12 species; but the only remarkable ones are the officinale or common gromwell, and the arvensa or bastard alkanet. Both these are natives of Britain; the former growing in dry gravelly soil, the latter in corn-fields.

LITHOTOMY. See Surgery.

LITTORELLA, a genus of the monœcia tetrandria class and order. The male cal. is four-leaved; cor. four-cleft; stam. long. No female cal.; cor. four-cleft, seed a nut. There is one species.

LIVER. See Anatomy.

LIVERY *of seisin*, in law, signifies delivering the possession of lands, &c. to him who has a right to them. There are two kinds of livery and seisin; livery in law

where the feoffer being in view of the land, house, or other thing granted, says to the feoffee, on delivery of the deed, "I give to you yonder land, &c. to hold to you and to your heirs, so go into the same, and take possession accordingly." And livery in deed, is where the parties, or the attorneys by them authorised, coming to the door of the house, or upon some part of the land, declare the occasion of their meeting before witnesses, read the deed, or its contents, and in case it be made by attorney, the letter of attorney is also read, after which, if the delivery is of a house, the grantor, or his attorney, takes the ring, key, or latch belonging to the door, or if it be a land, a turf, or clod of earth, and a twig of one of the trees, and delivering them with the deed to the grantee or his attorney, says, "I A. B. do hereby deliver to you possession and seisin of this messuage or tenement, &c. to hold to you, your heirs and assigns, according to the purport, true intent, and meaning of this indenture, or deed of feoffment." After which the grantee enters first alone, and shutting the door, and then opening it, lets in others.

Since the making the statute of uses, livery and seisin are not so much used as formerly; for a lease and release, a bargain and sale by deed inrolled, are sufficient to vest the grantee with possession, without the formality of livery.

LIVERYMEN of London, are a number of men selected from among the freemen of each company. Out of this body, the common council, sheriff, and other superior officers for the government of the city are elected, and they alone have the privilege of giving their votes for members of parliament; from which the rest of the citizens are excluded.

LIVES, or insurance of lives. See INSURANCE, and LIFE.

LIXIVIUM. See PHARMACY.

LIZARD. See LACERTA.

LOAD, or LODE, in mining, a word used especially in the tin-mines, for any regular vein or course, whether metallic or not; but most commonly load means a metallic vein. It is to be observed, that mines in general are veins within the earth, whose sides receding from or approaching to each other, make them of unequal breadths in different places, sometimes forming large spaces, which are called holes; these holes are filled like the rest with substances, which whether metallic, or of any other nature, are called loads. When the substances forming these loads are reducible to metal, the loads are by the English miners said to be alive, otherwise they are termed dead loads.

The load is frequently intercepted by the crossing of a vein of earth or stone, or some other metalline substance; in which case it generally happens, that one part of the load is moved to a considerable distance on one side. This load is by the miners termed a flooking, and the part of the load which is moved, is by them said to be heaved. This fracture or heave of a load, according to Mr. Price, is produced by a subsidence of the strata from their primary positions, which he supposes to have been horizontal or parallel to the surface of the earth, and therefore should more properly be called a depression than a heave. This heaving of the load would be an inexpressible loss to the miner, did not experience teach him that as the loads always run on the sides of the hills, so the part heaved is always moved toward the descent of the hill; so that the miner, working toward the ascent of the hill, and meeting a flooking, considers himself as working in the heaved part; wherefore, cutting through the flooking, he works upon its back up the ascent of the hill, till he recovers the load, and vice versa.

LOAMS. See HUSBANDRY.

LOANS, in political economy, sums of money, generally of large amount, borrowed from individuals or public bodies, for the service of the state. They are either compulsory, in which case they may be more properly termed requisitions; or voluntary, which is the only mode that can be frequently resorted to with advantage. Loans are sometimes furnished by public companies as a consideration for peculiar privileges secured to them; but are much more commonly advanced by individuals on a certain interest being allowed for the use of the money, either for a term of years, or until the principal shall be repaid.

The practice of borrowing money, for defraying part of the extraordinary expenses in time of war, had been adopted in other countries long before it was introduced into Great Britain; but it has been carried to a far greater extent here than by any other state: and the facility with which the government has been enabled to raise the largest sums, has arisen entirely from the strict punctuality with which it has constantly made good all pecuniary engagements. The chancellor of the exchequer is the officer who usually conducts negotiations of this kind on the part of the government, and the agreement is afterwards confirmed by parliament; the governor and company of the bank of England, have of late years been usually appointed receivers of the contributions, for which they have an allowance, at a certain rate per million; and the sums received by them are paid into the exchequer in the name of the chief cashier of the bank. The money appropriated to pay the interest or annuities, is issued at the receipt of the exchequer to the chief cashier of the bank upon account, and he is enjoined to pay the annuities, and render his account in due course. The bank detain their allowance for receiving the contributions out of the sum received, and likewise what they have allowed as discount to those subscribers who advanced their money before the times fixed for the several instalments.

When the parliament has voted the supplies, and the extent of the loan found necessary is determined, a communication is usually made to the bank or stock exchange stating the particular stock on which the loan is to be made, and fixing a day for those who intend to bid for it to wait on the minister with their proposals; in the mean time each person forms his list of friends who are to take different proportions with him in case he succeeds. When the day comes, each party offers as low as he thinks he can venture with a fair prospect of profit, and the lowest offer is generally accepted. The only step to be taken by those who are not of the number just mentioned, and who may wish to take a share in the transaction, is to apply to one of the subscribers for a part of his subscription, which at first may sometimes be had without any premium, or for a very small one, for it cannot be presumed

that any small number of men, who have subscribed for the whole sum to be raised, intend, or can keep it, but that they propose to include in their subscriptions a great number of their connections and acquaintance. Sometimes the subscription lies open to the public at the bank, as in the instance of the loan of eighteen millions for the service of the year 1797, and then every person is at liberty to subscribe what he thinks proper; and if upon casting up the whole, there is a surplus subscribed, which has generally been the case, the sum each person has subscribed, is reduced in an equal proportion, so as to make in the whole the sum fixed by parliament.

As soon as conveniently may be, after the subscription is closed, receipts are made out, and delivered to the subscribers, for the several sums by them subscribed; and for the conveniency of sale, every subscriber of a considerable sum has sundry receipts for different proportions of his whole sum, by which means he can readily part with what sum he thinks proper; and a form of assignment is drawn upon the back of the receipt, which being signed and witnessed, transfers the property to any purchaser. The deposit is generally ten per cent. and is made at or about the time of subscribing; the second payment is about a month after, and so on till the whole is paid in, each instalment being usually either ten or fifteen per cent. Those subscribers who choose to pay the whole sum before the appointed days of payment, are allowed discount at an agreed rate per cent. on the sum paid in advance, from the time of such payment to the period when the whole is required to be paid in by instalments. Those who do not complete the payment of the sum they have subscribed for, forfeit the part they have paid; and this is the case according to the acts of parliament, if the money is not paid by the days appointed; but payments are sometimes received after the appointed days on paying certain fees to the clerk.

Loans are usually raised upon either redeemable or irredeemable annuities. The former are those which according to the conditions of the acts by which they are created, government may redeem without the consent of the proprietors, by discharging the debt at par; the latter are such as being granted for specific terms, cannot be redeemed without the consent of the proprietors. The various debts that have been incurred at different periods by loans on either of these species of annuities, constitute the funded debt of the nation; that is, the debt which has been secured upon certain funds, created by parliament, and appropriated to the payment of the annual interest on the sums borrowed. The constant hope of being able at a future period to redeem the debts contracted, has induced the government generally to prefer raising money on annuities redeemable at par; and the disadvantage which might arise to the stock-holder from being paid off at par, if his principal bore a high rate of interest, has always made those who advance money on loans prefer a large capital bearing a low rate per cent. though it may actually produce a somewhat less annual interest than would have been given on a capital equal to the sum advanced: the great speculations which are carried on in the public funds are also a strong inducement to prefer advancing money on these conditions, which have contributed so much to increase the nominal magnitude of the national debt.

The terms of all the public loans which have been raised from the commencement of the funding system, have been collected by Mr. J. J. Grellier, who observes, that "the economy or extravagance of every transaction of this kind depends on its correspondence or disagreement with the price of the public funds, and the current rate of interest at which money could be obtained on good security at the time the bargain was concluded; and consequently, a loan on which the highest interest is paid, may have been obtained on the best terms that could possibly be made at the time it was negociated." The interest paid, however, forms the real burthen of each loan to the country, and is the circumstance to be chiefly attended to in all comparisons of the advantage or disadvantage of the terms on which the public debts have been contracted at different periods.

From the difference in the terms of the loan, with respect to the capital created, the rate of interest it bears, and the different periods of the terminable annuities which have been granted with most of the loans, it is evident, that in order to form a proper comparison of the rate of interest paid for the money borrowed at different periods, the various conditions must be brought into some degree of uniformity; and the most obvious mode of doing this is, by converting that part of the interest which consists of terminable annuities into equivalent perpetual annuities; that is, into the additional interest, which must have been paid in lieu of such terminable annuities.

The rate of interest at which such conversion is made affects the result in some instances very materially; thus, the perpetual annuity, which is equal to an annuity of 10*l.* for 21 years, is, at 3 per cent. 4*l.* 12*s.* 5*d.* but at 5 per cent. 6*l.* 8*s.* 2*d.*; and the perpetual annuity equal to an annuity of 10*l.* for 60 years, which at 3 per cent. is 8*l.* 6*s.* is at 5 per cent. 9*l.* 9*s.* 3*d.* from which it is evident, that, if the terminable annuities, granted at different periods, are all valued at the same rate of interest, the comparison will by no means be just; for if a high rate is adopted, the loans which have been obtained at the lowest interest will be set in an unfavourable view; and if, on the contrary, they are all valued at a low rate, the charge of those loans, for which the highest interest is paid, will appear less than it really is. Nor is a medium or average rate more proper for exhibiting the real difference in the terms on which the several loans have been obtained. The least objectionable mode appears to be to convert the terminable annuities into perpetual annuities, according to the current rate of interest at the time when the annuities were granted, as it is upon the rate of interest that the proportionate value of an annuity for a certain term to the perpetuity depends; and in forming the following statements, the conversion has been made at the interest produced by money invested in the three per cents. according to the price of this stock at the times when the terms of the respective loans were settled: for, though by this means, the rate is, in each case, rather lower than it would have been had the interest produced by 4 or 5 per cent. stock been adopted, it is most probable, from the nature of the principal loans, that the stock which must have been given in lieu of a long annuity, would chiefly have been three per cents.; and, therefore, the interest equivalent to the long annuity should be found according to the interest produced by this stock. It may also be

proper to remark, that, as the terminable annuities have mostly been granted for a long term, and form but a small part of the whole interest, particularly on the loans of the last war, the difference of a quarter or even half per cent. in the rate at which they are valued has in general but little effect on the whole rate per cent. of the loan. Thus, if the long annuity of the loan of 14,500,000*l.*, in 1797, is valued at 6 per cent. (being the interest produced by 3 per cents. at that time) it makes the whole rate per cent. 6*l.* 6*s.* 10*d.*; but, if the long annuity is valued at $5\frac{3}{4}$ per cent. it will be 6*l.* 6*s.* $9\frac{3}{4}$*d.*; at $5\frac{1}{2}$ per cent. 6*l.* 6*s.* $9\frac{1}{4}$*d.*; and, at 5 per cent. 6*l.* 6*s.* $8\frac{1}{2}$*d.* On the loan of 1798, the difference would be still less.

Till the last war, the lottery generally formed part of the terms of the loan; every subscriber of a certain sum towards the latter being entitled to a certain number of tickets, at 10*l.* each, the price at which the lottery-scheme is usually formed. As the whole profits of the lotteries were thus given up to the subscribers, a part of the money advanced must be considered as equivalent to the sum which government would otherwise have received for the lottery, and is therefore to be deducted from the whole sum advanced on the loan. This profit is variable, but has generally been taken at the average of 2*l.* 10*s.* per ticket; making, on a lottery of 50,000 tickets, 125,000*l.* to be deducted from the sum advanced, in estimating the rate of interest paid thereon.

There are some other circumstances which affect the interest paid: such as the discount allowed for prompt payment, the different periods of the instalments, and the times from which the annuities commence; but as these drawbacks do not in general amount to any considerable sum, in comparison with the whole amount of the loan, they do not materially augment the rate of interest; and as they more or less affect all the loans, they are of still less importance in a comparative view. In the following statement, however, a deduction is made on the loans of 18,000,000*l.* in 1796 and 1797, on account of the advantage allowed with respect to the time from which the annuities commenced, being greater than usual.

It is unnecessary to enter into a particular investigation of the interest paid for the money borrowed in the infancy of the funding system, as the first loans differed materially from those of subsequent periods, in being raised wholly on terminable annuities, and in having a particular fund assigned for each loan, by the supposed adequateness or insufficiency of which the interest required by the lenders was frequently influenced, as well as by other causes, which have since ceased to exist.

During the reign of queen Anne, loans were chiefly raised on annuities for 99 years, till 1711, when, by the establishment of the South Sea company, a variety of debts were consolidated and made a permanent capital, bearing 6 per cent. interest. About this period lotteries were also frequently adopted for raising money for the public service, under which form a considerable premium was given, in addition to a high rate of interest. This mode of raising money was followed in 1712, 1713, and 1714. In the latter year, though the interest paid was equal to only 5*l.* 7*s.* 2*d.* per cent. on the sum borrowed, the premium allowed was upwards of 34*l.* per cent.; but as peace was restored, and the legal rate of interest had been reduced to 5 per cent. it seems that a larger premium was allowed, for the sake of appearing to borrow at a moderate rate of interest.

In the reign of George I. the interest on a considerable part of the public debts was reduced to 5 per cent. and the few loans that were raised were comparatively of small amount; that of the year 1720 was obtained at little more than 4 per cent. interest.

About 1730 the current rate of interest was $3\frac{1}{2}$ per cent.; and in 1736, government was enabled to borrow at 3 per cent. per annum. The extraordinary sums necessary for defraying the expenses of the war which began in 1739, were at first obtained from the sinking fund and the salt duties; a payment from the bank, in 1742, rendered only a small loan necessary in that year, which was obtained at little more than 3 per cent. interest. In the succeeding years the following sums were raised by loans;

	Sum borrowed.	Interest.		
1743	*L* 1,800,000	*L* 3	8	4
1744	1,800,000	3	6	10
1745	2,000,000	4	0	7
1746	2,500,000	5	5	1
1747	4,000,000	4	8	0
1748	6,300,000	4	8	0
	Loans of the seven years war.			
1756	2,000,000	3	12	0
1757	3,000,000	3	14	3
1758	5,000,000	3	6	5
1759	6,600,000	3	10	9
1760	8,000,000	3	13	7
1761	12,000,000	4	1	11
1762	12,000,000	4	10	9
1763	3,500,000	4	4	2
	Loans of the American war.			
1776	2,000,000	3	9	8
1777	5,000,000	4	5	2
1778	6,000,000	4	18	7
1779	7,000,000	5	18	10
1780	12,000,000	5	16	8
1781	12,000,000	5	11	1
1782	13,500,000	5	18	1
1783	12,000,000	4	13	9
1784	6,000,000	5	6	11
	Loans of the war with the French republic.			
1793	4,500,000	4	3	4
1794	11,000,000	4	10	7
1795	18,000,000	4	15	8
1796	18,000,000	4	14	9
1796	7,500,000	4	12	2
1797	18,000,000	5	14	1
1797	14,500,000	6	6	10
1798	17,000,000	6	4	9
1799	3,000,000	5	12	5
1799	15,500,000	5	5	0
1800	20,500,000	4	14	2
1801	28,000,000	5	5	5
	Loans of the war with the French empire.			
1803	12,000,000	5	2	0
1804	14,500,000	5	9	2
1805	22,500,000	5	3	2
1806	20,000,000	4	19	7

LOASA, a genus of the polyandria monogynia class and order. The cal. is five-leaved; cor. five-petalled;

nect. five-leaved; caps. turbinate, one-celled, three-valved, many-seeded. There is one species, an annual of South America.

LOBE. See Anatomy.

LOBELIA, cardinal-flower, a genus of the monogamia order, in the syngenesia class of plants, and in the natural method ranking under the 29th order, companaceæ. The calyx is quinquefid; the corolla monopetalous and irregular; the capsule inferior, bilocular or trilocular. There are 42 species, but only four of them are cultivated in our gardens, two of which are hardy herbaceous plants for the open ground, and two shrubby plants for the stove. They are all fibrous-rooted perennials, rising with erect stalks from two to five or six feet high, ornamented with oblong, oval, spear-shaped, simple leaves, and spikes of beautiful monopetalous, somewhat ringent, five-parted flowers, of scarlet, blue, and violet colours. They are easily propagated by seeds, offsetts, and cuttings of their stalks. The tender kinds require the common treatment of other exotics. They are natives of America, from which their seeds must be procured.

The root of the species called the syphilitica (see Plate LXXXIV. Nat. Hist. fig. 252.) is an article of the materica medica. This species grows in most places in Virginia, and bears our winters. It is perennial, has an erect stalk three or four feet high, blue flowers, a milky juice, and a rank smell. The root consists of white fibres about two inches long, resembles tobacco in taste, which remains on the tongue, and is apt to excite vomiting. It is used by the North American Indians as a specific in the venereal disease. The benefit, however, to be derived from this article has not, as far as we know, been confirmed either in Britain or by the practitioners in Virginia.

LOCAL, in law, something fixed to the freehold, or tied to a certain place: thus, real actions are local, since they must be brought in the country where they lie, and local customs are those peculiar to certain countries and places.

Local problem, among mathematicians, such a one as is capable of an infinite number of different solutions, by reason that the point which is to resolve the problem may be indifferently taken within a certain extent, as suppose any where within such a line, within suce a plane figure, &c. which is called a geometric locus, and the problem is said to be a local or indetermined one.

A local problem may be either simple, when the point sought is in a right light; plane, when the point sought is in the circumference of a circle; solid, when the point required is in the circumference of a conic section; or lastly, sursolid, when the point is in the perimeter of a line of the second gender, or of a higher kind, as geometers call it.

LOCHIA. See Midwifery.

LOCK, a well-known instrument, and reckoned the masterpiece in smithery; a great deal of art and delicacy being required in contriving and varying the wards, spring, bolts, &c. and adjusting them to the places where they are to used, and to the various occasions of using them. From the various structure of locks, accommodated to their different intentions, they acquire various names. Those placed on outer doors are called stock-locks; those on chamber-doors, spring-locks; those on trunks, trunk-locks, padlocks, &c. Of these the spring-lock is the most considerable, both for its frequency and the curiosity of its structure.

A treatise upon this subject has been published by Mr. Joseph Bramah, who begins with observing, that the principle on which all locks depend, is the application of a lever to an interior bolt, by means of a communication from without; so that, by means of the latter, the lever acts upon the bolt, and moves it in such a manner as to secure the lid or door from being opened by any pull or push from without. The security of locks in general, therefore, depends on the number of impediments we can interpose betwixt the lever (the key) and the bolt which secures the door; and these impediments are well known by the name of wards, the number and intricacy of which alone are supposed to distinguish a good lock from a bad one. If these wards, however, do not in an effectual manner preclude the access of all other instruments besides the proper key, it is still possible for a mechanic of equal skill with the lock-maker to open it without the key, and thus to elude the labour of the other. "As nothing (says Mr. Bramah) can be more opposite in principle to fixed wards than a lock which derives its properties from the motion of all its parts, I determined that the construction of such a lock should be the subject of my experiment." In the prosecution of this experiment, he had the satisfaction to find that the least perfect of all his models fully ascertained the truth and certainty of his principle. The exclusion of wards made it necessary to cut off all communication between the key and the bolt; as the same passage which (in a lock simply constructed) would admit the key, might give admission likewise to other instruments. The office, therefore, which in other locks is performed by the extreme point of the key, is here assigned to a lever, which cannot approach the bolt till every part of the lock has undergone a change of position. The necessity of this change to the purposes of the lock, and the absolute impossibility of effecting it otherwise than with the proper key, are the points to be ascertained.

Plate LXXIX. Lock and Loom, fig. 4, represents a mortice lock, made under the patent which Mr. Stansbury took out in 1805, for various improvements in locks, in which A is the spring-latch, as in common; the end B of this is bent, and has a frame D screwed to it, carrying a roller E; against this roller a wedge F called a pusher, shown separately in fig. 5, acts; the spindle G on which this pusher is fixed, slides through holes in the side-plate of the lock, so as to have no shake, and on each end is fastened a handle; by this arrangement it is plain that when the handle of the wedge is pushed from without the door, its wedge E will act against the roller E, fig. 4, draw back the bolt A, and release the door; a continuation of the same motion opens it. The operations from within the room are the same, except that the handle of the pusher must be pulled instead of pushed; but as it is on the other end of the spindle, the operation on the wedge and bolt is the same. For the convenience of persons not acquainted with the new method, the bolt may be drawn back by turning the handle, as in the common lock. H is a piece of metal, figs. 4 and 5, which has a round collar a above, and another b beneath, which work in holes in the two

side-plates of the lock, so as to turn easily round; this piece has a hole through it, large enough to admit the pusher to move up and down; and an opening in one side thereof admits the wedge F; so that when the spindle is turned round, one of the two arms *d e* of this piece, acts against the arm B of the bolt A, fig. 4, and draws back the bolt when the handle is turned, as in the common way. In order to reduce the friction against the bolt, in shutting the door, a small roller *a*, fig. 1, is applied to it. In lieu of the slip-bolt of common locks, Mr. Stansbury uses a piece I; which has a spindle going through the plate of the lock, and projecting from the door with a handle on it, by which its arm *f* can be moved up and down, when the door is to be bolted; this handle is turned so that the knob *g* on the arm *f* may fall in the notch cut in the bolt to receive it; this prevents the bolt being moved back by the pusher, till the arm *f* is first removed. There is a spring at the back of this arm, which pressing against the plate of the lock, by its friction keeps it from falling by accident. K is the main bolt of the lock; it is kept steady by a rectangular opening, through which a screw passes. The bolt is moved by a circular iron plate, moving round a pin *h*, which is riveted into a circular bridge N, screwed to the plate shown separately in fig. 3; this bridge has a circular opening *i* in it, through which a pin *c*, riveted to the plate L, moves; this pin takes into a notch in the bolt, so as to move it backwards and forwards, when the plate is turned round its centre. The locking part is performed thus: the wheel L has a certain number of holes drilled in it, as at *m*; the bridge has the same number of similar holes in it, and in the same position; each hole in the bridge has a small pin in it, which is pushed in by a slight spring *n n n*, fig. 3.; when the holes in the plate coincide with the holes in the bridge, the springs *n n n* push up the pins through the plate, and lock them both together. The key, fig. 2, has the same number of pins projecting from its lower end, as the pin-holes in the bridge, and in the same position; the length of the pins is the same as the thickness of the plate L, fig. 4. When it is to be unlocked, the key is introduced, and as it is turned round, it is pushed gently forward against the plate; when the pins and key come opposite the pin-holes and pins, the force applied overcomes the resistance of the springs *n n n*, the pins are pushed out, and the key gets hold of the plate L, when being turned round, it draws the bolt back by the pin *b*, fig. 3.

LOCUS GEOMETRICUS, denotes a line by which a local or indeterminate problem is solved.

A locus is a line, any point of which may equally solve an indeterminate problem. Thus, if a right line suffice for the construction of the equation, it is called *locus ad rectum;* if a circle, *locus ad circulum;* if a parabola, *locus ad parabolum;* if an ellipsis, *locus ad elipsin;* and so of the rest of the conic sections. The loci of such equations as are right lines, or circles, the ancients called plane loci; and of those that are parabolas, hyperbolas, &c. solid loci. But Wolfius, and others among the moderns, divide the loci more commodiously into orders, according to the number of dimensions to which the indeterminate quantities rise. Thus, it will be a locus of the first order, if the equation is $x = \frac{ay}{c}$; a locus of the second or quadratic order, if $y^2 = ax^2$, or $y^2 = a^2 - x^2$; a locus of the third or cubic order, if $y^3 = a^2x$, or $y^2 = ax^2 - x^3$, &c.

All equations whose loci are of the first order, may be reduced to some one of the four following formulas: 1. $y = \frac{bx}{a}$. 2. $y = \frac{bx}{a} + c$. 3. $y = \frac{bx}{a} c$. 4. $y = c - \frac{bx}{a}$: where the unknown quantity y, is supposed always to be freed from fractions, and the fraction that multiplies the other unknown quantity x, to be reduced to this expression, $\frac{b}{a}$, and all the known terms to c.

All loci of the second degree are conic sections, viz. either the parabola, the circle, ellipsis, or hyperbola: if an equation, therefore, is given, whose locus is of the second degree, and it is required to draw the conic section which is the locus thereof, first draw a parabola, ellipsis, or hyperbola; so as that the equations expressing the natures thereof may be as compound as possible, in order to get general equations or formulas, by examining the peculiar properties whereof we may know which of these formulas the given equation ought to have regard to; that is, which of the conic sections will be the locus of the proposed equation. This known, compare all the terms of the proposed equation with the terms of the general formula of that conic section, which you have found will be the locus of the given equation; by which means you will find how to draw the section which is the locus of the equation given.

If an equation, whose locus is a conic section, is given, and the particular section whereof it is the locus is required; all the terms of the given equation being brought over to one side, so that the other is equal to nothing, there will be two cases.

Case I. When the rectangle $x\, y$ is not in the given equation. 1. if either $y\, y$ or $x\, x$ is in the same equation, the locus will be a parabola. 2. If both $x\, x$ and $y\, y$ are in the equation with the same signs, the locus will be an ellipsis or a circle. 3. If $x\, x$ and $y\, y$ have different signs, the locus will be an hyperbola, or the opposite sections regarding their diameters.

Case II. When the rectangle $x\, y$ is in the given equation. 1. If neither of the squares $x\, x$ or $y\, y$, or only one of them, is in the same, the locus of it will be as hyperbola between the asymptotes. 2. If $y\, y$ and $x\, x$ is therein, having different signs, the locus will be an hyperbola regarding its diameters. 3. If both the squares $x\, x$ and $y\, y$ are in the equation, having the same signs, you must free the square $y\, y$ from fractions; and then the locus will be an hyperbola, when the square of $\frac{1}{2}$ the fraction multiplying $x\, y$, is equal to the fraction multiplying $x\, x$; an ellipsis, or circle, when the same is less; and an hyperbola, or the opposite sections, regarding their diameters, when greater.

LOCUST. See GRYLLUS.

LODGMENT, in military affairs, is a work raised with earth, gabions, fascines, woolpacks, or mantelets, to cover the besiegers from the enemy's fire, and to prevent their losing a place which they have gained, and are resolved, if possible, to keep. For this purpose, when a lodgment is to be made on the glacis, covered way, or in the breach, there must be great provision made of fascines, sand-bags, &c. in the trenches; and during the action, the poineers with fascines, sand-bags, &c. should

be making the lodgment, in order to form a covering in as advantageous a manner as possible from the opposite bastion, or the place most to be feared.

LOEFLINGIA, a genus of the class and order triandria monogynia. The calyx is five-leaved; corolla five-petalled; capsule one-celled, three-valved. There is one species, an annual of Spain.

LOESELIA, a genus of the didynamia angiospermia class of plants, the flower of which is monopetalous and quinquefid at the limb; the fruit is a trilocular capsule, with several angulated seeds in each cell. There is one species, a herb of South America.

LOG, in naval affairs, is a flat piece of wood, shaped somewhat like a flounder, with a piece of lead fastened to its bottom, which makes it stand or swim upright in the water. To this log is fastened a long line, called the log-line; and this is commonly divided into certain spaces 50 feet in length by knots, which are pieces of knotted twine inreeved between the strands of the line; which show, by means of a half-minute glass, how many of these spaces or knots are run out in half a minute. They commonly begin to be counted at the distance of about 10 fathoms or 60 feet from the log; so that the log, when it is hoven overboard, may be out of the eddy of the ship's wake before they begin to count: and for the ready discovery of this point of commencement, there is commonly fastened at it a red rag.

The log being thus prepared, and hoven overboard from the poop, and the line veered out by the help of a reel, as fast as the ship sails from it, will show how far the ship has run in a given time, and consequently her rate of sailing.

Hence it is evident, that as the distance of the knots bears the same proportion to a mile as half a minute does to an hour, whatever number of knots the ship runs in half a minute, the same number of miles she will run in an hour, supposing her to run with the same degree of velocity during that time; and therefore, in order to know her rate of sailing, it is the general way to heave the log every hour; but if the force or direction of the wind varies, and does not continue the same during the whole hour, or if there has been more sail set, or any sail handed in, by which the ship has sailed faster or slower than she did at the time of heaving the log, there must then be an allowance made for it accordingly.

Log-board, a table generally divided into five columns, in the first of which is entered the hour of the day; in the second the course steered: in the third, the number of knots run off the reel each time of heaving the log; in the fourth, from what point the wind blows; and in the fifth, observations on the weather, variation of the compass, &c.

Log book, a book ruled in columns like the log-board, into which the account on the log-board is transcribed every day at noon; whence, after it is corrected, &c. it is entered into the journal. See Navigation.

Log-wood, in commerce. See Hæmatoxylum.

Logwood is used by dyers for dying blacks and blues.

LOGARITHMIC, in general, something belonging to logarithms. See Logarithms.

Logarithmic curve. If on the line AN (Plate LXXVIII. Miscel., fig. 155.) both ways indefinitely extended, be taken, AC, CE, EG, GI, IL, on the right hand, and A *g*, *g* P, &c. on the left, all equal to one another, and if at the points P, *g*, A, C, E, G, I, L, be erected to the right line AN, the perpendiculars PS, *gd*, AB, CD, EF, GH, IK, LM, which let be continually proportional, and represent numbers, viz. AB, 1; CD, 10; EF, 100, &c. then shall we have two progressions of lines, arithmetical and geometrical: for the lines AC, AE, AG, &c. are in arithmetical progression, or as 1, 2, 3, 4, 5, &c. and so represent the logarithms to which the geometrical lines AB, CD, EF, &c. do correspond. For since AG is triple of the right line AC, the number GH shall be in the third place from unity, if CD is in the first; so likewise shall LM be in the fifth place, since AL = 5 AC. If the extremities of the proportionals S, *d*, B, D, F, &c. are joined by right lines, the figure SBML will become a polygon, consisting of more or less sides, according as there are more or less terms in the progression.

If the parts AC, CE, EG, &c. are bisected in the points *c*, *e*, *g*, *i*, *l*, and there are again raised the perpendiculars *cd*, *ef*, *gh*, *ik*, *lm*, which are mean proportionals between AB, CD; CD, EF, &c. then there will arise a new series of proportionals, whose terms beginning from that which immediately follows unity, are double of those in the first series, and the difference of the terms is become less, and approaches nearer to a ratio of equality, than before. Likewise, in this new series, the right lines AL, A*c*, express the distances of the terms LM, *cd*, from unity, viz. since AL is ten times greater than A*c*, LM shall be the tenth term of the series from unity; and because A*e* is three times greater than A*c*, *ef* will be the third term of the series if *cd* is the first, and there shall be two mean proportionals between AB and *ef*; and between AB and LM there will be nine mean proportionals. And if the extremities of the lines B*d*, D*f*, F*h*, &c. are joined by right lines, there will be a new polygon made, consisting of more but shorter sides than the last.

If, in this manner, mean proportionals are continually placed between every two terms, the number of terms at last will be made so great, as also the number of the sides of the polygon, as to be greater than any given number, or to be infinite; and every side of the polygon so lessened, as to become less than any given right line; and consequently the polygon will be changed into a curvelined figure: for any curve-lined figure may be conceived as a polygon whose sides are infinitely small and infinite in number. A curve described after this manner, is called logarithmical.

It is manifest, from this description of the logarithmic curve, that all numbers at equal distances are continually proportional. It is also plain, that if there are four numbers, AB, CD, IK, LM, such that the distance between the first and second, is equal to the distance between the third and fourth, let the distance from the second to the third be what it will, these numbers will be proportional. For because the distance AC, IL, are equal, AB shall be to the increment Ds, as IK is to the increment MT. Wherefore, by composition, AB : DC : IK : ML. And contrariwise, if four numbers are proportional, the distance between the first and second shall be equal to the distance between the third and fourth.

The distance between any two numbers, is called the logarithm of the ratio of those numbers; and, indeed, does not measure the ratio itself, but the number of terms in a

$\frac{n-1}{2}x^2 + n \times \frac{n-1}{2} \times \frac{n-2}{3}x^3$, &c. we shall have $1 + nx + n \times \frac{n-1}{2}x^2 + n \times \frac{n-1}{2} \times \frac{n-2}{3}x^3$, &c. $= \text{N}$.

But since n, from the nature of the logarithms, is here supposed indefinitely great, it is evident that the numbers connected to it by the sign — may all be rejected, as far as any assigned number of terms.

For as 1, 2, 3, &c. are indefinitely small in comparison to n, the rejecting of those numbers can very little affect the values to which they belong.

If, therefore, 1, 2, 3, &c. be thrown out of the factors $\frac{n-1}{2}, \frac{n-2}{3}, \frac{n-3}{4}$, &c. we shall have $1 + nx + \frac{n^2x^2}{2} + \frac{n^3x^3}{2.3} + \frac{n^4x^4}{2.3.4}$, &c. $= \text{N}$.

But $nx\ (=\text{L})$ is the hyperbolic logarithm of $(1+x)^n$, or N, by what has been before specified; and therefore $1 + \text{L} + \frac{\text{L}^2}{2} + \frac{\text{L}^3}{2.3} + \frac{\text{L}^4}{2.3.4}$, &c. $= \text{N} =$ number required.

Of the method of using a Table of Logarithms.—Having explained the method of making a table of the logarithms of numbers greater than unity, the next thing to be done is, to show how the logarithms of fractional quantities may be found. And, in order to this, it may be observed, that as we have hitherto supposed a geometric series to increase from an unit on the right hand, so we may now suppose it to decrease from an unit towards the left; and the indices, in this case, being made negative, will still exhibit the logarithms of the terms to which they belong.

Thus Log.	— 3	— 2	— 1	0	+ 1	+ 2	+ 3, &c.
Num.	$\frac{1}{1000}$	$\frac{1}{100}$	$\frac{1}{10}$	1	10	100	1000, &c.

Whence + 1 is the logarithm of 10, and — 1, the logarithm of $\frac{1}{10}$; + 2 the logarithm of 100, and — 2 the logarithm of $\frac{1}{100}$, &c.

And from hence it appears that all numbers, consisting of the same figures, whether they be integral, fractional, or mixed, will have the decimal parts of their logarithms the same.

Thus, the logarithm of 5874 being 3.7689339, the logarithm of $\frac{1}{10}, \frac{1}{100}, \frac{1}{1000}$, &c. part of it will be as follows:

Num.	Logarithms.
5 8 7 4	3.7 6 8 9 3 3 9
5 8 7.4	2.7 6 8 9 3 3 9
5 8.7 4	1.7 6 8 9 3 3 9
5.8 7 4	0.7 6 8 9 3 3 9
.5 8 7 4	—1.7 6 8 9 3 3 9
.0 5 8 7 4	—2.7 6 8 9 3 3 9
.0 0 5 8 7 4	—3.7 6 8 9 3 3 9

From this it also appears, that the index, or characteristic, of any logarithm, is always one less than the number of figures which the natural number consists of: and this index is constantly to be placed on the left hand of the decimal part of the logarithm.

When there are integers in the given number, the index is always affirmative; but when there are no integers, the index is negative, and is to be marked by a line drawn before it, like a negative quantity in algebra.

Thus, a number having 1, 2, 3, 4, 5, &c. integer places, the index of its log. is 0, 1, 2, 3, 4, &c. And a fraction having a digit in the place of primes, seconds, thirds, fourths, &c. the index of its logarithm will be — 1, — 2, — 3, — 4, &c.

It may also be observed, that though the indices of fractional quantities are negative, yet the decimal parts of their logarithms are always affirmative; and all operations are to be performed by them in the same manner as by negative and affirmative quantities in algebra.

In taking out of a table the logarithm of any number not exceeding 10000, we have the decimal part by inspection; and if to this the proper characteristic be affixed, it will give the complete logarithm required.

But if the number, whose logarithm is required, be above 10000, then find the logarithm of the two nearest numbers to it that can be found in the table, and say, as their difference : the difference of their logarithms : : the difference of the nearest number and that whose logarithm is required : the difference of their logarithms, nearly; and this difference being added to, or subtracted from, the nearest logarithm, according as it is greater or less than the required one, will give the logarithm required, nearly.

Thus, let it be required to find the logarithm of 367182.

The decimal part of 3671 is by the table .5647844; and of 3672 is .5649027;

$$\therefore \begin{array}{l}\text{The} \\ \text{log. of}\end{array} \left\{ \begin{array}{l} 367100 \text{ is } 5.5647844 \\ 367200 \text{ is } 5.5649027 \end{array} \right\}$$

$$\begin{array}{lll} \text{Their diff.} & 100 & .0001183 \text{ diff.} \end{array}$$

$$\begin{array}{l}\text{Nearest No.} \\ \text{Given No.}\end{array} \left\{ \begin{array}{l} 367200 \\ 367182 \end{array} \right.$$

$$18 \text{ diff.}$$

Therefore 100 : 0001183 :: 18 : 0000212.

And 5.5649027 — .0000212 = 5.5648815 = logarithm of 367182, nearly.

If the number consists both of integers and fractions, or is entirely fractional, find the decimal part of the logarithm as if all its figures were integral; and this, being prefixed to the proper characteristic, will give the logarithm required.

And if the given number is a proper fraction, subtract the logarithm of the denominator from the logarithm of the numerator, and the remainder will be the logarithm sought; which, being that of a decimal fraction, must always have a negative index.

And, if it is a mixed number, reduce it to an improper fraction, and find the difference of the logarithms of the numerator and denominator, in the same manner as before.

In finding the number answering to any given logarithm, the index, if affirmative, will always show how many integral places the required number consists of; and, if negative, in what place of decimal the first, or significant figure, stands; so that, if the logarithm can be found in the table, the number answering to it will always be had by inspection.

But, if the logarithm cannot be exactly found in the table, find the next greater, and the next less, and then say, As the difference of these two logarithms : the difference of the numbers answering to them : : the difference of the given logarithm, and the nearest tabular

logarithm : a fourth number; which added to, or subtracted from, the natural number answering to the nearest tabular logarithm, according as that logarithm is less or greater than the given one, will give the number required, nearly.

Thus, let it be required to find the natural number answering to the logarithm 5.5648815.

The next less and greater logarithms, in the table, are

5.5647844	The numbers	367100
5.5649027	answering	367200
Their diff. .0001183		100

And 55649027 — 5.5648815 = 0000212.

Therefore .0001183 : 100 : : 0000212 : 18 nearly.

Whence 367200 — 18 = 377182 = number required.

The Use and Application of Logarithms.—It is evident, from what has been said of the construction of logarithms, that addition of logarithms must be the same thing as multiplication in common arithmetic; and subtraction in logarithms the same as division; therefore, in multiplication by logarithms, add the logarithms of the multiplicand and multiplier together, their sum is the logarithm of the product.

		num.	logarithms.
Example.	Multiplicand	8.5	0.9294189
	Multiplier	10	1.0000000
	Product	85	1.9294189

And in division, subtract the logarithm of the divisor from the logarithm of the dividend, the remainder is the logarithm of the quotient.

		num.	logarithms.
Example.	Dividend	9712.8	3.9873444
	Divisor	456	2.6589648
	Quotient	21.3	1.3283796

To find the Complement of a Logarithm.—Begin at the left hand, and write down what each figure wants of 9, only what the last significant figure wants of 10; so the complement of the logarithm of 456, viz. 2.6589648, is 7.3410352.

In the Rule of Three. Add the logarithms of the second and third terms together, and from the sum subtract the logarithm of the first, the remainder is the logarithm of the fourth. Or, instead of subtracting a logarithm, add its complement, and the result will be the same.

To raise Powers by Logarithms.—Multiply the logarithm of the number given, by the index of the power required, the product will be the logarithm of the power sought.

Example. Let the cube of 32 be required by logarithms. The logarithm of 32 = 1.5051500, which multiplied by 3, is 4.5154500, the logarithm of 32768, the cube of 32. But in raising powers, viz. squaring, cubing, &c. of any decimal fraction by logarithms, it must be observed, that the first significant figure of the power be put so many places below the place of units, as the index of its logarithm wants of 10, 100, &c. multiplied by the index of the power.

To extract the Roots of Powers by Logarithms.—Divide the logarithm of the number, by the index of the power, the quotient is the logarithm of the root sought.

To find Mean Proportionals between any two numbers. Subtract the logarithm of the least term from the logarithm of the greatest, and divide the remainder by a number more by one than the number of means desired then add the quotient to the logarithm of the least term (or subtract it from the logarithm of the greatest continually, and it will give the logarithms of all the mean proportionals required.

Example. Let three mean proportionals be sought, between 106 and 100.

Logarithm of 106 = 2.0253059
Logarithm of 100 = 2.0000000

Divide by 4)0.0253059(0.0063264.75

Log. of the least term 100 added		2.0000000
Log. of the 1st mean	101.4673846	2.0063264.75
Log. of the 2d mean	102.9563014	2.0126529.5
Log. of the 3d mean	104.4670483	2.0189794.25
Log. of the greatest term	106.	2.0253059.

LOGIC. The professed business of logic is to express the nature of the human mind, and the proper manner of conducting its several powers, in order to the attainment of truth and knowledge.

Those, therefore, who have treated expressly of this subject, have endeavoured first to define and describe the several faculties and operations of the human mind, as perception, judgment, memory, invention, &c. They next proceed to lay down rules for correct reasoning and argument. Every act of the judgment they term a *proposition*, and all propositions are either affirmative or negative. All questions or arguments they reduce to syllogisms, that is, from two axioms or propositions (called *terms*, in the technical language) laid down, they deduce a third, or conclusion, and the previous propositions they divide into major and minor. Thus, let the question be, *Whether God is an intelligent being?* Here the major or principal propositions proceeds from the word intelligent, and the minor respects God. They would then arrange the syllogism as follows:

Maj. To dispose things in right and perfect order is the work of an intelligent Being:
Min. But God has disposed creation in right and perfect order;
Conclusion. Therefore God is an intelligent Being.

They next class or arrange the different kinds of syllogisms according to the nature of them. Propositions are not only affirmative and negative, but they are also particular or universal. Hence syllogisms will vary not only as the major or minor proposition is negative or affirmative, but as either is an universal or particular affirmative, &c. Hence they dispose the several kinds of propositions into modes, and the syllogisms into figures, according as they affect the subject or the predicate. The modes are indicated by the letters, *a*, *e*, *i*. *o*, as they are affirmative or negative, universal or particular. There are nineteen modes and four figures. The first figure is when the middle term is the subject of the major, and the predicate of the minor: as,

No work of God is bad:
But the natural passions and appetites of men are the work of God;
Therefore they are not bad.

This figure includes four modes, denoted by the words, "Barbara, celarent, Darii, ferio;" referring to the vowels which each syllable contains.

10,000*l.* if the method determined the longitude to 1° of a great circle, or to 60 geographical miles; of 15,000*l.* if it determined it to 40 miles; and of 20,000*l.* if it determined it to 30 miles; with this proviso, that if any such method extend no further than 30 miles adjoining to the coast, the proposer should have no more than half the rewards. The act also appoints the first lord of the admiralty, the speaker of the house of commons, the first commissioner of trade, the admirals of the red, white, and blue squadrons, the master of the Trinity-house, the president of the royal society, the royal astronomer at Greenwich, the two Savilian professors at Oxford, and the Lucasian and Plumian professors at Cambridge, with several other persons, as commissioners for the longitude at sea. The Lowndian professor at Cambridge was afterwards added. After this act of parliament, several other acts passed in the reigns of George II. and III. for the encouragement of finding the longitude. At last, in 1774, an act passed, repealing all other acts, and offering separate rewards to any person who should discover the longitude, either by the watch keeping true time within certain limits, or by the lunar method, or by any other means. The act proposes as a reward for a timekeeper, the sum of 5000*l.* if it determine the longitude to 1° or 60 geographical miles; the sum of 7500*l.* if it determine it to 40 miles; and the sum of 10,000*l.* if it determine it to 30 miles, after proper trials specified in the act. If the method is by improved solar and lunar tables, constructed upon sir Isaac Newton's theory of gravitation, the author shall be entitled to 5000*l.* if such tables shall show the distance of the moon from the sun and stars, within fifteen seconds of a degree, answering to about seven minutes of longitude, after allowing half a degree for the errors of observation. And for any other method, the same rewards are offered as those for timekeepers, provided it gives the longitude true within the same limits, and is practicable at sea. The commissioners have also a power of giving smaller rewards, as they shall judge proper, to any one who shall make any discovery for finding the longitude at sea, though not within the above limits: provided, however, that if such person or persons shall afterwards make any further discovery as to come within the above-mentioned limits, such sum or sums as they may have received shall be considered as part of such greater reward, and deducted therefrom accordingly.

To find the longitude by a time-keeper. The sun appears to move round the earth from east to west, or to describe 360°, in 24 hours, and therefore he appears to move 15° in an hour. If therefore the meridians of two places make an angle of 15° with each other, or if the two places differ 15° in longitude, the sun will come to the eastern meridian one hour before he comes to the western meridian, and therefore when it is 12 o'clock at the former place, it is only eleven at the latter; and in general, the difference between the times by the clock at any two places, will be the difference of their longitudes, converted into time at the rate of 15° for an hour, the time at the eastern place being the forwardest. If, therefore, we can tell what o'clock it is at any two places at the same instant of time, we can find the difference of their longitudes, by allowing 15° for every hour that the clocks differ.

Let, therefore, the timekeeper be well regulated and set to the time of Greenwich, that being the place from which we reckon our longitude; then if the watch neither gains nor loses, it will always show the time at Greenwich, wherever you may be. Now to find the time by the clock at any other place, take the sun's altitude, and thence find the time; now the time thus found is apparent time, or that found by the sun, which differs from the time shown by the clock by the equation of time. We must, therefore, apply the equation of time to the time found by the sun, and we shall get the time by the clock; and the difference between the time by the clock so found, and the time by the timekeeper, or the time at Greenwich, converted into degrees at the rate of 15° for an hour, gives the longitude of the place from Greenwich. For example: let the time by the timekeeper, when the sun's altitude was taken, be 6h. 19′, and let the time deduced from the sun's altitude be 9h. 27′, and suppose at that time the equation of time to be 7′, showing how much the sun is that day behind the clock, then the time by the clock is 9h. 34′, the difference between which and 6h. 19′, is 3h. 15′; and this converted into degrees, at the rate of 15° for 1 hour, gives 48° 45′, the longitude of the place from Greenwich; and as the time is forwarder than that at Greenwich, the place lies to the east of Greenwich. Thus the longitude could be very easily determined, if you could depend upon the timekeeper. But as a watch will always gain or lose, before the timekeeper is sent out, its gaining or losing every day for some time, a month for instance, is observed; this is called the rate of going of the watch, and from thence the mean rate of going is thus found:

Suppose I examine the rate of a watch for 30 days; on some of those days I find it has gained, and on some it has lost; add together all the quantities it has gained, and suppose they amount to 17″; add together all the quantities it has lost, and suppose they amount to 13″; then upon the whole, it has gained 4″ in 30 days; and this is called the mean rate for that time; and this divided by 30, gives 0″,133 for the mean daily rate of gaining; so that if the watch had gained regularly 0″,133 every day, at the end of 30 days it would have gained just as much as it really did gain, by sometimes gaining and sometimes losing. Or you may get the mean daily rate thus: Take the difference between what the clock was too fast or too slow on the first and last days of observation, if it be too fast or too slow on each day; but take the sum, if it is too fast on one day and too slow on the other, and divide by the number of days between the observations, and you get the mean daily rate. Thus, if the watch was too fast on the first day 18″, and too fast on the last day 32″, the difference 14″ divided by 30, gives 0″,466, the mean daily rate of gaining. But if the watch was too fast on the first day 7″, and too slow on the last day 10″, the sum 17″ divided by 30, gives 0″,566, the mean daily rate of losing. After having thus got the mean daily rate of gaining or losing, and knowing how much the watch was too fast or too slow at first, you can tell, according to that rate of going, how much it is too fast or too slow at any other time. In the first case, for instance, let the watch have been 1′ 17″ too fast at first, and I want to know how much it is too fast 50 days after that time: now it gains 0″,133 every day; if this is multiplied by 50, it gives 7″,65 for the whole gain in 50 days; there-

fore, at the end of that time, the watch would be 1′. 23″,65 to fast. This would be the error, if the watch continued to gain at the above rate; and although, from the different temperatures of the air, and the imperfection of the workmanship, this cannot be expected, yet the probable error will by this means be diminished, and it is the best method we have to depend upon. In watches which are under trial at the Royal Observatory at Greenwich, as candidates for the rewards, this allowance of a mean rate is admitted, although it is not mentioned in the act of parliament: the commissioners, however, are so indulgent as to grant it, which is undoubtedly favourable to the watches.

As the rate of going of a watch is subject to vary from so many circumstances, the observer, whenever he goes ashore, and has sufficient time, should compare his watch for several days with the true time found by the sun, by which he will be able to find its rate of going. And when he comes to a place whose longitude is known, he may then set his watch to Greenwich time; for when the longitude of a place is known, you know the difference between the time there and at Greenwich. For instance, if he go to a place known to be 30° east longitude from Greenwich, his watch should be two hours slower than the time at that place. Find therefore the true time at that place, by the sun, and if the watch is two hours slower, it is right; if not, correct it by the difference, and it again gives Greenwich time.

In the year 1726, Mr. John Harrison produced a timekeeper of his own construction, which did not err above one second in a month for ten years together; and in the year 1736 he had a machine tried in a voyage to and from Lisbon, which was the means of correcting an error of almost a degree and a half in the computation of the ship's reckoning. In consequence of this success, Mr. Harrison received public encouragement to proceed, and he made three other time-keepers, each more accurate than the former, which were finished successively in the years 1739, 1758, and 1761; the last of which proved so much to his own satisfaction, that he applied to the commissioners of the longitude to have this instrument tried in a voyage to some port in the West Indies, according to the directions of the statute of the 12th of Anne above cited. Accordingly, Mr. William Harrison, son of the inventor, embarked in November 1761, on a voyage for Jamaica, with this fourth timekeeper or watch; and on his arrival there, the longitude, as shown by the timekeeper, differed but one geographical mile and a quarter from the true longitude, deduced from astronomical observations. The same gentleman returned to England with the timekeeper, in March 1762, when he found that it had erred in the four months, no more than 1′ 54″$\frac{1}{2}$ in time, or 28$\frac{5}{8}$ minutes of longitude; whereas the act requires no greater exactness than 30 geographical miles, or minutes of a great circle, in such a voyage. Mr. Harrison now claimed the whole reward of 20,000*l.* offered by the said act: but some doubts arising in the minds of the commissioners concerning the true situation of the island of Jamaica, and the manner in which the time at that place had been found, as well as at Portsmouth; and it being farther suggested by some, that although the timekeeper happened to be right at Jamaica, and after its return to England, it was by no means a proof that it had been always so in the intermediate time; another trial was therefore proposed, in a voyage to the island of Barbadoes, in which precautions were taken to obviate as many of these objections as possible. Accordingly the commissioners previously sent out proper persons to make astronomical observations on that island, which, when compared with other corresponding ones made in England, would determine, beyond a doubt, its true situation; and Mr. William Harrison again set out with his father's timekeeper, in March 1764, the watch having been compared with equal altitudes at Portsmouth before he set out, and he arrived at Barbadoes about the middle of May; where, on comparing it again by equal altitudes of the sun, it was found to show the difference of longitude between Portsmouth and Barbadoes to be 3h. 55m. 3s.; the true difference of longitude between these places, by astronomical observations, being 3h. 54m. 20.; so that the error of the watch was 43s., or 10′ 45″ of longitude. In consequence of this and the former trials, Mr. Harrison received one moiety of the reward offered by the 12th of queen Anne, after explaining the principles on which his watch was constructed, and delivering this, as well as the three former, to the commissioners of the longitude for the use of the public: and he was promised the other moiety of the reward, when other timekeepers should be made on the same principles, either by himself or others, performing equally well with that which he had last made. In the mean time, this last timekeeper was sent down to the Royal Observatory at Greenwich, to be tried there under the direction of the Rev. Dr. Maskelyne, the astronomer-royal. But it did not appear, during this trial, that the watch went with the regularity that was expected; from which it was apprehended that the performance even of the same watch was not at all times equal; and consequently that little certainty could be expected in the performance of different ones. Moreover the watch was now found to go faster than during the voyage to and from Barbadoes by 18 or 19 seconds in 24 hours; but this circumstance was accounted for by Mr. Harrison, who informs us that he had altered the rate of its going by trying some experiments, which he had not time to finish before he was ordered to deliver up the watch to the board. Soon after this trial, the commissioners of longitude agreed with Mr. Kendal, one of the watch-makers appointed by them to receive Mr. Harrison's discoveries, to make another watch on the same construction with this, to determine whether such watches could be made from the account which Mr. Harrison had given, by other persons as well as himself. The event proved the affirmative; for the watch produced by Mr. Kendal, in consequence of this agreement, went considerably better than Mr. Harrison's did. Mr. Kendal's watch was sent out with captain Cook, in his second voyage towards the south pole and round the globe, in the years 1772, 1773, 1774, and 1775; when the only fault found in the watch was, that its rate of going was continually accelerated; though in this trial of three years and a half it never amounted to 14″$\frac{1}{2}$ a day. The consequence was, that the house of commons, in 1774 to whom an appeal had been made, were pleased to order the second moiety of the reward to be given to Mr. Harrison, and to pass the act above-mentioned. Mr. Harrison had also at different times received some other sums of money,

as encouragements to him to continue his endeavours, from the board of longitude, and from the India company, as well as from many individuals. Mr. Arnold and some other persons have since also made several very good watches for the same purpose, and have been remunerated for their skill and labour.

Others have proposed various astronomical methods for finding the longitude. These methods chiefly depend on having an ephemeris or almanac suited to the meridian of some place, as Greenwich for instance, to which the Nautical Almanac is adapted, which shall contain for every day computations of the times of all remarkable celestial motions and appearances, as adapted to that meridian. So that if the hour and minute is known when any of the same phenomena are observed in any other place whose longitude is desired, the difference between this time and that to which the time of the said phenomenon was calculated and set down in the almanac, will be known, and consequently the difference of longitude also becomes known between that place and Greenwich, allowing at the rate of fifteen degrees to an hour.

Now it is easy to find the time at any place, by means of the altitude or azimuth of the sun or stars, which time it is necessary to find by such means, both in these astronomical modes of determining the longitude, and in the former by a timekeeper; and it is the difference between that time, so determined, and the time at Greenwich, known either by the timekeeper or by the astronomical observations of celestial phenomena, which gives the difference of longitude at the rate above-mentioned. Now the difficulty in these methods lies in the fewness of proper phenomena, capable of being thus observed; for all slow motions, such as belong to the planet Saturn, for instance, are quite excluded, as affording too small a difference, in a considerable space of time, to be properly observed; and it appears that there are no phenomena in the heavens proper for this purpose, except the eclipses or motions of Jupiter's satellites, and the eclipses or motions of the moon, viz. such as her distance from the sun or certain fixed stars lying near her path, or her longitude or place in the zodiac, &c. Now of these methods,

1st. That by the eclipses of the moon is very easy, and sufficiently accurate, if they did but happen often, as every night. For at the moment when the beginning or middle or end of an eclipse is observed by a telescope, there is no more to be done but to determine the time by observing the altitude or azimuth of some known star; which time being compared with that in the tables, set down for the happening of the same phenomenon at Greenwich, gives the difference in time, and consequently of longitude sought. But as the beginning or end of an eclipse of the moon cannot generally be observed nearer than one minute, and sometimes two or three minutes of time, the longitude cannot certainly be determined by this method, from a single observation, nearer than one degree of longitude. However, by two or more observations, as of the beginning and end, &c. a much greater degree of exactness may be attained.

2d. The moon's place in the zodiac is a phenomenon more frequent than her eclipses; but then the observation of it is difficult, and the calculus perplexed and intricate, by reason of two parallaxes; so that it is hardly practicable to any tolerable degree of accuracy.

3d. But the moon's distances from the sun or certain fixed stars, are phenomena to be observed many times in almost every night, and afford a good practical method of determining the longitude of a ship at almost any time; either by computing from thence the moon's true place, to compare with the same in the almanac; or by comparing her observed distance itself with the same as there set down.

From the great improvements made by Newton in the theory of the moon, and more lately by Euler and others on his principles, professor Mayer, of Gottingen, was enabled to calculate lunar tables more correct than any former ones; having so far succeeded as to give the moon's place within one minute of the truth, as has been proved by a comparison of the tables with the observations made at the Greenwich observatory by Dr. Bradley, and by Dr. Maskelyne, the late astronomer-royal; and the same have been still farther improved under his direction, by the late Mr. Charles Mason, by several new equations, and the whole computed to tenths of a second. These tables, when compared with the above-mentioned series of observations, a proper allowance being made for the unavoidable error of observation, seem to give always the moon's longitude in the heavens correctly within 30 seconds of a degree; which greatest error, added to a possible error of one minute in taking the moon's distance from the sun or a star at sea, will at a medium only produce an error of 42 minutes of longitude. To facilitate the use of the tables, Dr. Maskelyne proposed a nautical ephemeris, the scheme of which was adopted by the commissioners of longitude, and first executed in the year 1767, since which time it has been regularly continued. But as the rules that were given in the appendix to one of those publications, for correcting the effects of refraction and parallax, were thought too difficult for general use, they have been reduced to tables. So that, by the help of the ephemeris, these tables, and others that are also provided by the board of longitude, the calculations relating to the longitude, which could not be performed by the most expert mathematician in less than four hours, may now be completed with great ease and accuracy in half an hour.

As this method of determining the longitude depends on the use of the tables annually published for this purpose, those who wish for farther information are referred to the instructions that accompany them, and particularly to those that are annexed to the tables requisite to be used with the Astronomical and Nautical Ephemeris.

4th. The phenomena of Jupiter's satellites have commonly been preferred to those of the moon, for finding the longitude; because they are less liable to parallaxes than these are, and besides they afford a very commodious observation whenever the planet is above the horizon. Their motion is very swift, and must be calculated for every hour.

Now, to find the longitude by these satellites: with a good telescope observe some of their phenomena, as the conjunction of two of them, or of one of them with Jupiter, &c. and at the same time find the hour and minute, from the altitudes of the stars, or by means of a clock or watch, previously regulated for the place of observation; then, consulting tables of the satellites, observe the time when the same appearance happens in the meridian of the

place for which the tables are calculated; and the difference of time, as before, will give the longitude.

The eclipses of the first and second of Jupiter's satellites are the most proper for this purpose; and as they happen almost daily, they afford a ready means of determining the longitude of places at land, having indeed contributed much to the modern improvements in geography; and if it were possible to observe them with proper telescopes, in a ship under sail, they would be of great service in ascertaining its longitude from time to time. To obviate the inconvenience to which these observations are liable from the motions of the ship, Mr. Irwin invented what he called a marine chair: this was tried by Dr. Maskelyne, in his voyage to Barbadoes, when it was found that no benefit could be derived from the use of it. And indeed, considering the great power requisite in a telescope proper for these observations, and the violence as well as irregularities in the motion of a ship, it is to be feared that the complete management of a telescope on shipboard will always remain among the desiderata in this part of nautical science. And farther, since all methods that depend on the phenomena of the heavens, have also this other defect, that they cannot be observed at all times, this renders the improvement of timekeepers of the greater importance.

LONICERA, *honeysuckle*, a genus of the monogynia order, in the pentandria class of plants. The corolla is monopetalous and irregular; the berry polyspermous, bilocular, and inferior. There are 19 species, of which the most remarkable are,

1. The alpigena, or upright red-berried honeysuckle, rises with a shrubby, short, upright stem, four or five feet high.

2. The cærulea, or blue-berried honeysuckle, with a shrubby upright stem, three or four feet high, and many white flowers proceeding from the sides of the branches.

3. The nigra, or black-berried upright honeysuckle, with a shrubby stem three or four feet high, and white flowers succeeded by single and distinct black berries.

4. The tartarica, or Tartarian honeysuckle, with a shrubby upright stem, three or four feet high, heart-shaped opposite leaves, and whitish erect flowers succeeded by red berries, sometimes distinct, and sometimes double.

5. The diervilla, or yellow-flowered Arcadian honeysuckle, with shrubby upright stalks, to the height of three or four feet, and clusters of pale yellow flowers, appearing in May and June, and sometimes continuing till autumn.

4. The xylosteum, or fly honeysuckle, with a strong shrubby stem, branching erect to the height of seven or eight feet, and erect white flowers proceeding from the sides of the branches.

7. The symphoricarpos, or shrubby St. Peter's-wort, with a shrubby rough stem, four or five feet high, and small greenish flowers.

8. The periclymenum, or common climbing honeysuckle, has two principal varieties, viz. the English wild honeysuckle, or woodbine of the woods and hedges, and the Dutch or German honeysuckle, with a shrubby declinated stalk, and long trailing purplish branches, furnishing large beautiful red flowers of a fragrant odour, appearing in June and July.

9. The caprifolium, or Italian honeysuckle, with shrubby declinated stalks, sending out long slender trailing branches, terminated by verticillate or whorled bunches of close-sitting flowers, very fragrant, and white, red, and yellow colours.

10. The sempervirens, or evergreen trumpet-flowered honeysuckle, with a shrubby declinated stalk, sending out long slender trailing branches, terminated by naked verticillate spikes, of long, unreflexed, deep-scarlet flowers, very beautiful, but of little fragrance.

LOOF, in the sea language, is a term used in various senses; thus the loof of a ship is that part of her aloft which lies just before the chest-trees; hence the guns which lie there are called loof-pieces: keep your loof, signifies, keep the ship near to the wind: to loof into a harbour, is to sail into it close by the wind: loof up, is to keep nearer the wind: to spring the loof, is when a ship that was going large before the wind, is brought close by the wind.

Loof-tackle, is a tackle in a ship which serves to lift goods of small weight in or out of her.

LOOKING-GLASSES. See Optics.

LOOM, the weaver's frame, a machine whereby several distinct threads are woven into one piece. Looms are of various structures, accommodated to the various kinds of materials to be woven, and the various manner of weaving them, viz. for woollens, silks, linens, cottons, cloths of gold, and other works, as tapestry, ribands, stockings, &c. See Weaving.

The weaver's loom-engine, otherwise called the Dutch loom-engine, was brought into use from Holland to London, in or about the year 1676.

The lower compartment of Plate LXXIX. Lock and Loom, represents a loom for weaving silks or other plain work. A, fig. 6, is a roll called the cloth-beam, on which the cloth is wound as it is wove; at one end it has a racket-wheel *a*, and a click to prevent its running back; at the same end it has also four holes in it, and is turned by putting a stick in these holes: at the other end of the loom is another roll B, on which the yarn is wound; this has two small cords *bb* wrapped round it, the ends of which are attached to a bar *d*, which has a weight D hung to it; by this means a friction is caused, which prevents the roll B turning by accident. EF are called lambs; they are composed of two sticks *efki*, between which are fastened a great number of threads; to the bar *e* are fastened two cords *gh*, which pass over pulleys, and are fastened to the bar *h* of the lamb F; the lower bars of each lamb are connected by cords with the treadles GH; the workman sits on the seat K, and places his feet upon these treadles; as they are connected together by the cords *gh*, when he presses down one, it will raise the other, and the lambs with them; a great number of threads, according to the width of the cloth, are wound round the yarn-beam B, and are stretched to the cloth-beam A; the middle of the threads which compose the lamb EF, have loops (called eyes) in them, through which the threads between the rolls AB, which are called the warp, are passed; the first thread of the warp goes through the loops of the lambs E, the next attached to the lamb F, and so on alternately; by this means, when the weaver presses down one of the treadles with his foot and raises the other, one lamb draws up every other thread,

and the other sinks all the rest, so as to make an opening between the sets of thread: LL is a frame moving on a centre at the top of the frame of the loom; the lower part of this frame is shown in fig. 8; LL are the two uprights of the frame, *l* is the bar that connects them, M is a frame carrying a great number of pieces of split reed or sometimes fine wire at equal distances; between these the threads of the warp are passed; the frame M is supported by a piece of wood *m* called the shuttle-race, which is fastened into the front of the pieces LL; each end of this piece has boards nailed to the sides, so as to form troughs NO; at a small distance above these are fixed two very smooth wires *no;* their use is to guide the two pieces *pq*, called peckers or drivers; to each of these pieces a string is fastened, and these strings are tied to a piece of wood P, which the weaver holds in his hand, and by snatching the stick to either side, draws the pecker forwards very quick, and gives the shuttle, fig. 7. (which is to be laid in the trough before the pecker) a smart blow, and drives it along across the race *m* into the other trough, where it pushes the pecker along to the end of the wire, ready for the next stroke which throws it back again, and so on. Fig. 7. represents the under side of the shuttle on a larger scale; its ends are pointed with iron; it has a large mortise through the middle of it, in which is placed a quill *a* containing the yarn; *b* is a piece of glass, called the eye of the shuttle, with a hole in it, through which comes the end of the thread; *dd* are two small wheels to make it run easily on the race. The operations are as follow: the workman sitting upon the seat K. holds the stick P in his right hand, and takes hold of one of the bars of the frame LL with his left; presses his foot on one of the treadles GH, which by means of the lambs EF, as before described, divides the warp; he then snatches the stick P, and by that means throws the shuttle, fig. 7, which unwinds the thread in it, and leaves it lying in between the threads of the warp; he then relieves the treadle he before kept down, and presses down the other; while he is doing this, he with his left hand draws the frame LL towards him, and then returns it. The use of this is to beat the last thread thrown by the shuttle close up to the one that was thrown before it by the split reeds M, fig. 8. As soon as he has brought the frame LL back to its original position, and again divided the warp by the treadle, he throws the shuttle again: when he has in this manner finished about 12 or 14 inches of cloth, he winds it up by turning the roll A with the stick, as before described. Some very expert weavers will throw the shuttle and perform the other operations at the rate of 120 times per minute.

Loom, in the sea language. When a ship appears big when seen at a distance, they say she looms.

Loom gale, a gentle easy gale of wind, in which a ship can carry her topsails atrip.

LOOP, in the iron works, denotes a part of a sow or block of cast iron, broken or melted off from the rest.

LOPHIUS, *fishing-frog, toad-fish,* or *sea-devil,* a genus of the branchiostegious order of fishes, whose head is in size equal to all the rest of the body. There are three species, the most remarkable of which is the piscatorius, or common fishing-frog, an inhabitant of the British seas. This singular fish grows to a large size, some being between four and five feet in length; and Mr. Pennant mentions one taken near Scarborough, whose mouth was a yard wide. The fishermen on that coast have a great regard for this fish, from a supposition that it is a great enemy to the dog-fish; and whenever they take it with their lines, set it at liberty. The head of this fish is much larger than the whole body, is round at the circumference, and flat above; the mouth of a prodigious wideness. The under jaw is much longer than the upper; the jaws are full of slender sharp teeth; in the roof of the mouth are two or three rows of the same. On each side the upper jaw are two sharp spines, and others are scattered about the upper part of the head. The body grows slender near the tail, the end of which is quite even. The colour of the upper part of this fish is dusky; the lower part white; the skin smooth.

LORANTHUS, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 48th order, aggregatæ. The germen is inferior; there is no calyx; the corolla is sexfid and revoluted; the stamina are at the tops of the petals; the berry is monospermous. There are 18 species, natives of America.

LORD. See Peer.

LORD'S DAY. No person upon the Lord's day shall serve or execute any writ, process, warrant, order, judgment, or decree (except in cases of treason, felony, or breach of the peace) but the service thereof shall be void.

LOTTERIES are declared to be public nuisances, 5 Geo. I. c. 9.; but for the public service of the government, lotteries are frequently established by particular statutes, and managed by special officers and persons appointed.

By stat. 42 Geo. III. c. 54, lottery-office keepers are to pay 50*l*. for every licence in London, Edinburgh, and Dublin, or within 20 miles of either, and 10*l*. for every licence for every other office; and licensed persons shall deposit 30 tickets with the receiver general of the stamp-duties, or licence to be void.

By stat. 22 Geo. III. c. 47, lottery-office keepers must take out a licence; and offices are to be open only from eight in the morning to eight in the evening, except the Saturday evening preceding the drawing. The sale of chances and shares of tickets, by persons not being proprietors thereof, is prohibited under penalty of 50*l*.; and by 42 Geo. III. c. 119, all games or lotteries called *little goes*, are declared public nuisances, and all persons keeping any office or places for any game or lottery, not authorized by law, shall forfeit 500*l*. and be deemed rogues and vagabonds. The proprietor of a whole ticket may nevertheless insure it for its value only, with any licensed office for the whole time of drawing from the time of insurance, under a bona fide agreement without a stamp.

LOTUS, or *bird's-foot trefoil,* a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The legumen is cylindrical, and very erect, the alæ closing upwards longitudinally; the calyx is tubulated. There are 23 species, but only five or six are usually cultivated in our gardens.

1. The siliquosus, or winged pea, has trailing, slender, branchy stalks, about a foot long, with trifoliate oval leaves, and from the axillas of the branches, large, papilionaceous, red flowers, one on each footstalk, suc-

ceeded by tetragonous solitary pods, having a membranous wing or lobe, running longitudinally at each corner. It flowers in June and July, and the seeds ripen in autumn. 2. The creticus, or Cretan silvery lotus. 3. The Jacobæus, or black lotus of St. James's island. 4. The hirsutus, or hairy Italian lotus. 5. The dorcynium, white Austrian lotus, or shrub trefoil of Montpelier. 6. The edulis, with yellow flowers.

The first species is a hardy annual. The other species may be propagated either by seeds or cuttings, but require to be kept in pots in the greenhouse during the winter season.

LOUIS, or Knights of St. Louis, the name of a military order in France, instituted by Louis XIV. in 1693.

LOUSE. See Pediculus.

LOXIA, a genus of birds of the order of passeres, the distinguishing characters of which are: the bill is strong, convex above and below, and very thick at the base; the nostrils are small and round; the tongue is as if cut off at the end; the toes are four, placed three before and one behind, excepting one species; which has only two toes before and one behind. The most remarkable are:

1. The curvirostra, or common cross-bill, is about the size of a lark, is known by the singularity of its bill, both mandibles of which curve opposite ways and cross each other: the general colour of the plumage in the male is of a red-lead, inclining to rose-colour, and more or less mixed with brown; the wings and tail are brown; the legs black. The female is of a green colour, more or less mixed with brown in those parts where the male is red. This species is a constant inhabitant of Sweden, Germany, Poland, Switzerland, Russia, and Siberia, where it breeds; but migrates sometimes in vast flocks into other countries, as is now and then the case in respect to England; for though in some years a few are met with, yet in others it has been known to visit there by thousands, fixing on such spots as are planted with pines, for the sake of the seeds, which are its natural food: it is observed to hold the cone in one claw like the parrot, and to have all the actions of that bird when kept in a cage. It is also found in North America and Greenland; and is said to make its nest in the highest parts of the fir-trees, fastening it to the branch with the resinous matter which exudes from the trees.

2. The coccothraustes, or hawfinch, is in length seven inches. This species is ranked among the British birds; but only visits those kingdoms occasionally, and for the most part in winter, and is never known to breed there. It is more plenty in France. It feeds on berries, kernels, &c. and from the great strength of the bill, it cracks the stones of the fruit of the haws, cherries, &c. with the greatest ease.

3. The pyrrhula, or bulfinch, is so generally known as almost to supercede description. This species is common in most parts of the continent of Europe, and throughout Russia and Siberia, at which last places it is caught for the table. In winter it approaches gardens and orchards, and has been generally stigmatised for making havock among the buds of trees. From some late observations however, it would appear, that the object of these birds is not the bud, but "the worm in the bud;" and that this species, in conjunction with various other species of small birds, are the frequent means of defending the embryo fruits, and thence promoting their growth to maturity; for the warmth that swells the buds, not only hatches eggs of unnumbered tribes of insects, whose parent flies, by an unerring instinct, laid them there, but brings forward a numerous race already in a caterpillar state, that now issue from their concealments, and make their excursion along the budding branches, and would probably destroy every hope of fruitage, but for those useful instruments for its preservation, whose young are principally fed by eating caterpillars. The bulfinch, in its wild state, has only a plain note; but when tamed, it becomes remarkably docile, and may be taught any tune after a pipe, or to whistle any note in the best manner; it seldom forgets what it has learned; and will become so tame as to come at call, perch on its master's shoulder, and (at command) go through a difficult musical lesson. They may be also taught to speak, and some thus instructed are annually brought to London from Germany.

4. The cardinalis, or cardinal grossbeak, near eight inches in length. The bill stout, and of a pale-red colour; the irides a hazel; the head is greatly crested, the feathers rising up to a point when erect; round the bill, and on the throat, the colour is black, the rest of the bird of a fire-red. The female differs from the male, being mostly of a reddish brown. This species is met with in several parts of North America, and has attained the name of Virginia nightingale, from the fineness of its song, the note of which resembles that of the nightingale.

5. The orix, or grenadier grossbeak, is about the size of a house-sparrow. The forehead, sides of the head, and chin, are black, the breast and belly the same; the wings are brown, with pale edges; and the rest of the body of a beautiful red colour. These birds are inhabitants of St. Helena; they are also in plenty at the Cape of Good Hope, where they frequent watery places that abound with reeds, and among which they are supposed to make their nest. If, as is supposed, this is the same with Kolben's finch, he says that the nest is of a peculiar contrivance, made with small twigs, interwoven very closely and tightly with cotton, and divided into two apartments with but one entrance, the upper for the male, the lower for the female, and is so tight as not to be penetrated by any weather. He adds, that the bird is scarlet only in summer, being in the winter wholly ash-coloured. These birds, seen among the green reeds, are said to have a wonderful effect: for, from the brightness of their colours, they appear like so many scarlet lilies. See Plate LXXXIV. Nat. Hist. fig. 253.

6. The pensilis, or pensile grossbeak, (the toddy-bird of Fryer) is about the size of the house-sparrow: the bill is black; the irides are yellow; the head, throat, and forepart of the neck, the same; from the nostrils springs a dull green stripe, which passes through the eye and beyond it, where it is broader; the hind part of the head and neck, the back, rump, and wing-coverts, are of the same colour; the quills are black, edged with green; the belly is deep grey, and the vent of a rufous red; the tail and legs are black. This species is found at Madagascar; and fabricates a nest of a curious construction, composed of straw and reeds interwoven in shape of a bag, the opening beneath. It is fastened above to a twig of

some tree; mostly to those growing on the borders of streams. On one side of this, within, is the true nest. The bird does not form a new nest every year, but fastens a new one to the end of the last; and often as far as five in number, one hanging from another. These build in society like rooks, often five or six hundred being seen on one tree. They have three young at each hatch. See Plate LXXXIV. Nat. Hist. fig. 254.

7. The bengalensis, or Bengal grossbeak, is a trifle bigger than a house-sparrow. The female lays three or four eggs.

8. The socia, or sociable grossbeak, is about the size of a bullfinch; the general colour of the body above is a rufous brown, the under parts yellowish. It inhabits the interior country at the Cape of Good Hope, where it was discovered by colonel Paterson. These birds, according to our author, live together in large societies, and their mode of nidification is extremely uncommon. They build in a species of mimosa which grows to an uncommon size. In one described by col. Paterson, there could be no less a number than from 800 to 1000 residing under the same roof. He calls it a roof, because it perfectly resembles that of a thatched house; and the ridge forms an angle so acute and so smooth, projecting over the entrance of the nest below, that it is impossible for any reptile to approach them. The industry of these birds " seems almost equal (says our author) to that of the bee: throughout the day they appear to be busily employed in carrying a fine species of grass, which is the principal material they employ for the purpose of erecting this extraordinary work, as well as for additions and repairs. Though my short stay in the country was not sufficient to satisfy me by ocular proofs, that they added to their nest as they annually increased in numbers, still from the many trees which I have seen borne down with the weight, and others which I have observed with their boughs completely covered over, it would appear that this is really the case. When the tree which is the support of this aerial city is obliged to give way to the increase of weight, it is obvious that they are no longer protected, and are under the necessity of rebuilding in other trees. One of these deserted nests I had the curiosity to break down, so as to inform myself of the internal structure of it, and found it equally ingenious with that of the external. There are many entrances, each of which forms a regular street, with nests on both sides, at about two inches distant from each other.

9. The tridactyla, or three-toed grossbeak, (the guifso balito of Buffon) has only three toes, two before and one behind. The bill is toothed on the edges; the head, throat, and fore-part of the neck, are of a beautiful red; the upper part of the neck, back, and tail, are black; the wing-coverts brown, edged with white; quills brown, with greenish edges; and legs a dull red; the wings reach half-way on the tail. This species inhabits Abyssinia, where it frequents woods, and is a solitary species.

According to Linnæus there are 48 species of the loxia.

LOZENGE, Lozange, *rhombus*, in geometry, a quadrilateral figure, consisting of four equal and parallel sides, two of whose opposite angles are acute, and the other two obtuse; the distance between the two obtuse ones being always equal to the length of one side: when the sides are unequal, this figure is called a rhomboides.

Lozenge, in heraldry, a rhombus, or figure of equal sides, but unequal angles.

Lozenge, in pharmacy, the same with what is otherwise called troche.

LUCANUS, *stag-chaffer*, a genus of insects of the order coleoptera: the generic character is, antennæ clavated, with compressed tip, divided into lamellæ on the inner side; jaws stretched forwards, exserted, and toothed. The principal species is the lucanus cervus, commonly known by the name of the stag-beetle, or stag-chaffer. It is the largest of all the European coleopterous insects, sometimes measuring nearly two inches and a half in length, from the tips of the jaws to the end of the body. Its general colour is a deep chesnut, with the thorax and head, which is of a squarish form, of a blacker cast; and the jaws are often of a brighter or redder chesnut-colour than the wings-shells; the legs and under-parts are coal-black, and the wings, which, except during flight, are concealed under the shells, are large, and of a fine pale yellowish-brown. This remarkable insect is chiefly found in the neighbourhood of oak-trees, delighting in the sweet exsudation or honey-dew so frequently observed on the leaves. Its larva, which perfectly resembles that of the genuine beetles, is also found in the hollows of oak-trees, residing in the fine vegetable mould usually seen in such cavities, and feeding on the softer parts of the decayed wood. It is of very considerable size, of a pale yellowish or whitish-brown colour; and when stretched out at full length, measures nearly four inches. When arrived at its full size, which, according to some, is hardly sooner than the fifth or sixth year, it forms, by frequently turning itself, and moistening it with its glutinous saliva, a smooth oval hollow in the earth, in which it lies, and afterwards remaining perfectly still for the space of near a month, divests itself of its skin, and commences pupa or chrysalis. It is now of a shorter form than before, of a rather deeper colour, and exhibits in a striking manner the rudiments of the large extended jaws and broad head so conspicuous in the perfect insect: the legs are also proportionally larger and longer than in the larva state. The ball of earth in which this chrysalis is contained is considerably larger than a hen's egg, and of a rough exterior surface, but perfectly smooth and polished within. The chrysalis lies about three months before it gives birth to the complete insect, which usually emerges in the months of July and August. The time, however, of this insect's growth and appearance in all its states varies much, according to the difference of seasons. It is not very uncommon in many parts of England.

The commonly supposed female differs so much in appearance from the male, that it has by some authors been considered as a dictinct species. It is not only smaller than the former, but totally destitute of the long and large ramified jaws, instead of which it has a pair of very short curved ones, slightly denticulated on their inner side: the head is also of considerably smaller diameter than the thorax. In point of colour it resembles the former.

The exotic species of this genus are mostly natives of America, and one in particular, frequently found in Virginia, is so nearly allied to the English stag-beetle as

hardly to differ, except in having fewer denticulations or divisions on the jaws.

A highly elegant species has lately been discovered in New Holland. This differs from the rest in being entirely of a beautiful golden-green colour, with short, sharp-pointed, denticulated jaws of a brilliant copper-colour. The whole length of the insect is rather more than an inch. There are seven species of the lucanus.

LUCIDA, in astronomy, an appellation given to several fixed stars on account of their superior brightness; as the lucida coronæ, a star of the second magnitude in the northern crown; the lucida hydræ; or cor hydræ; and the lucida lyræ, a star of the first magnitude in that constellation.

LUDWIGIA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. The corolla is tetrapetalous; the calyx quadripartite, superior; the capsule tetragonal quadrilocular, inferior, and polyspermous. There are four species, annuals of the West Indies.

LUES. See MEDICINE.

LUMBAGO. See MEDICINE.

LUMBRICUS, the *worm*, in zoology; a genus of insects belonging to the order of vermes intestina. The body is cylindrical, annulated, with an elevated belt near the middle, and a vent-hole on its side. There are two species of this animal: 1. Lumbricus terrestris, the earth or dew worm, Mr. Barbut observes, differs extremely in colour and external appearance in the different periods of its growth, which has occasioned people little acquainted with the variations of this kind of animals to make four or five different species of them. The general colour is a dusky red. They live under ground. never quitting the earth but after heavy rains, or at the approach of storms. The method to force them out is, either to water the ground with infusions of bitter plants, or to trample on it. The bare motion on the surface of the soil drives them up, in fear of being surprised by their formidable enemy, the mole. The winding progression of the worm is facilitated by the inequalities of its body, armed with small, stiff, sharp-pointed bristles: when it means to insinuate itself into the earth, there oozes from its body a clammy liquor, by means of which it slides down. It never damages the roots of vegetables. Its food is a small portion of earth, which it has the faculty of digesting. The superfluity is ejected by way of excrement, under a vermicular appearance. Earth-worms are hermaphrodites. 2. The marinus, marine worm, or lug, (see Plate LXXXIV. Nat. Hist. fig. 255.) is of a pale red colour, and the body is composed of a number of annular joints; the skin is scabrous, and all the rings or joints are covered with little prominences, which render it extremely rough to the touch. It is an inhabitant of the mud about the sea-shores, and serves for food to many kinds of fish. The fishermen bait their hooks and nets with it.

LUNAR CAUSTIC. } See SILVER, CHEMISTRY, and
LUNA CORNEA. } SALTS, *Detonating*.

LUNARIA, SATIN-FLOWER, MOONWORT, or HONESTY, a genus of the siliculosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. The silicula is entire, elliptical, compressed-plane, and pedicellated; with the valves equal to the partition, parallel, and plane; the leaves of the calyx are alternately fritted at the base. There are three species. This plant is famous in some parts of England for its medicinal virtues, though it has not the fortune to be received in the shops. The people in the northern countries dry the whole plant in an oven, and give as much as will lie on a shilling for a dose twice a day in hemorrhages of all kinds, and with great success. The Welch, among whom it is not uncommon, Dr. Needham informs us, make an ointment of it, which they use externally, and pretend it cures dysenteries.

LUNATIC. See IDEOT.

LUNGS. See ANATOMY, and PHYSIOLOGY.

LUPINUS, *lupin*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is bilabiated; there are five oblong and five roundish antheræ; the legumen is coriaceous. There are ten species, chiefly hardy herbaceous flowery annuals, rising with upright stalks from one to three or four feet high, ornamented with digitate or fingered leaves, and terminated by long whorled spikes of papilionaceous flowers, white, blue, yellow, and rose-coloured. They are all easily raised from seed, and succeed in any open borders, where they make a fine variety.

LUPUS, in astronomy, a southern constellation, consisting of 19, or, according to Flamsteed, of 24 stars.

LUSTRATION, in antiquity, sacrifices or ceremonies by which the ancients purified their cities, field, armies, or people, defiled by any crime or impurity.

LUSTRE, a term signifying the gloss or brightness which appears on the external surface of a mineral, or on the internal surface when newly broken. The first is called the external, the second internal lustre. Two particulars respecting lustre require attention, viz. the degree, and the kind.

1. With respect to degree, Dr. Thomson gives five terms of comparison, viz. 1. very brilliant; 2. brilliant; 3. sub-brilliant; 4. glimmering, that is, having only certain parts brilliant; 5. dull, or without lustre.

2. With respect to kind, the lustre is either metallic or common. The common lustre is subdivided into vitreous or glossy, silky, waxy or greasy, mother of pearl, diamond, and semi-metallic.

LUTE, a stringed instrument formerly much in use; anciently containing only five rows of strings, but to which six, or more, were afterwards added. The lute consists of four parts, viz. the table; the body, which has nine or ten sides; the neck, which has as many stops or divisions; and the head, or cross, in which screws for tuning it are inserted. In playing this instrument, the performer strikes the strings with the fingers of the right hand, and regulates the sounds with those of the left hand. The origin of this instrument is not known, though generally believed to be of very early date. Indeed, authors are not agreed as to the country to which we are indebted for its invention. Some give it to Germany, and derive its name from the German word lutue, which signifies the same thing, while others ascribe it to the Arabians, and trace its name from the Arabic alland.

LUTES. In many chemical operations the vessels must

be covered with something to preserve them from the violence of the fire, from being broken or melted; and also to close exactly their joinings to each other, in order to retain the substances which they contain, when they are volatile, and reduced to vapour.

The coating used for retorts, &c. to defend them from the action of the fire, is usually composed of nearly equal parts of coarse sand, and refractory clay. These matters ought to be well mixed with water and a little hair, so as to form a liquid paste, with which the vessels are covered, layer upon layer, till it is of the required thickness. The sand mixed with the clay is necessary to prevent the cracks which are occasioned by the contracting of the clay during its drying, which it always does when pure. The hair serves also to bind the parts of the lute, and to keep it applied to the vessel; for, notwithstanding the sand which is introduced into it, some cracks are always formed, which would occasion pieces of it to fall off.

The lutes with which the joinings of vessels are closed, are of different kinds, according to the nature of the intended operations, and of the substances to be distilled in these vessels.

When vapours of watery liquors, and such as are not corrosive, are to be contained, it is sufficient to surround the joining of the receiver, to the nose of the alembic, or of the retort, with slips of paper or linen, covered with flour paste. In such cases also, slips of wet bladder are very conveniently used.

When more penetrating and dissolving vapours are to be contained, a lute is to be employed of quick-lime, slacked in air, and beaten into a liquid paste with whites of eggs. This paste is to be spread upon linen slips, which are to be applied exactly to the joining of the vessel. This lute is very convenient, easily dries, becomes solid, and sufficiently firm.

Lastly, when saline, acid, and corrosive vapours are to be contained, we must then have recourse to the lute called fat-lute. This lute is made by forming into a paste some dried clay finely powdered, sifted through a silken searce, and moistened with water; and then, by beating this paste well in a mortar with boiled linseed-oil, that is, oil which has been rendered dry by litharge dissolved in it, this lute easily takes and retains the form given to it. It is generally rolled into cylinders of a convenient size. These are to be applied. by flattening them, to the joinings of the vessels, which ought to be perfectly dry; because the least moisture would prevent the lute from adhering. When the joinings are closed with this fat-lute, the whole is to be covered with slips of linen spread with a lute of lime and whites of eggs. These slips are to be fastened with pack-thread. The second lute is necessary to keep on the fat-lute, because the latter remains soft, and does not become solid enough to stick on alone.

Ground linseed made into a paste with water makes also a very useful lute for most occasions.

LUTHERANS, the christians who follow the opinions of Martin Luther, one of the principal reformers of the church in the sixteenth century. See Gregory's Church History, vol. ii.

LUXATION. See SURGERY.

LYCHNIS, *campion*, a genus of the pentagynia order, in the pentandria class of plants, and in the natural method ranking under the 22d order, caryophylleæ. The calyx is monophyllous, oblong, and smooth; there are five unguiculated petals, with the segments of the limbs almost bifid; the capsule quinquelocular. There are 12 species, the principal are, 1. The chalcedonica, or chalcedonian scarlet. Of this there are varieties, with single scarlet flowers, with large double scarlet flowers of exceeding beauty and elegance, with pale red flowers, and with white flowers. Of these varieties the double scarlet lychnis is superior to all for size and elegance, the flowers being large, very double, and collected into a very large bunch, exhibit a charming appearance; the single scarlet kind is also very pretty, and the others effect an agreeable variety with the scarlet kinds. 2. The diurna: the varieties are, the common single red-flowered bachelor's button, double red, double white, and single white-flowered. The double varieties are exceeding ornamental in their bloom; the flower large, very double, and continue long in blow; the single red sort grows wild by ditch-sides and other moist places in many parts of England; from which the doubles were accidentally obtained by culture in gardens. 3. The viscaria, or viscous German lychnis, commonly called catch-fly. Of this also there are varieties with single red flowers, with double red flowers, and with white flowers. The double variety is considerably the most eligible for general culture, and is propagated in plenty by parting the roots. All the varieties of this species emitting a glutinous liquid matter from their stalks, flies happening to light on them sometimes stick and entangle themselves, whence the plant obtains the name catch-fly. 4. The flos cuculi, cuckoo-flower lychnis. The flowers having each petal deeply quadrifid in a torn or ragged-like manner, the plant obtained the name of ragged robin. There are varieties with single and double flowers. The double sort is a large flower; it is an improved variety of the single, which grows wild in most of our moist meadows, and is rarely cultivated; but the double, being very ornamental, merits culture in every garden.

LYCIUM, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 28th order, luridæ. The corolla is tubular, having its throat closed up with the beard of the filaments; the berry is bilocular. There are eight species, natives of various countries, and chiefly shrubs.

LYCOPERDON, a genus of the natural order of fungi, belonging to the cryptogamia class of plants. The fungus is roundish, and full of farinaceous seeds. Dr. Withering reckons 25 species, of which the following are the most remarkable: 1. The tuber, truffles, or subterraneous puff-balls, is a native of woods both in England and Scotland. It is a subterraneous fungus, growing generally in clusters 3 or 4 inches under ground, without any visible root. The figure of it is nearly spherical, the size that of a potatoe; the exterior coat at first white, afterwards black, and studded with pyramidical or polyhedrous tubercles; the internal substance solid and callous, of a dirty-white or pale-brown colour, grained like a nutmeg with serpentine lines; in which, according to Micheli, are imbedded minute oval capsules, containing each from 2 to 4 round watered seeds. The truffles of Great Britain seldom exceed 3 or 4 ounces in weight; but in Italy, and some other parts of the continent, they

are said to have been found of the enormous size of 8, and even 14 pounds. They have a volatile and somewhat urinous smell, and are reputed to be aphrodisical. 2. The bovista, or common puff-ball, is frequent in meadows and pastures in the autumn. It varies exceedingly in size, figure, superfices, and colour. In general, it consists of a sack or bag, having a root at its base, and the bag composed of 3 membranes, an epidermis, a tough white skin, and an interior coat which adheres closely to the central pith. The pith in the young plants is of a yellowish colour, at first firm and solid, but soon changes into a cellular spongy substance, full of a dark dull-green powder, which discharges itself through an aperture at the top of the fungus, which aperture is formed of lacerated segments, in some varieties reflexed. The powder is believed to be the seeds, which through a microscope appear of a spherical form, and to be annexed to elastic hairs.

LYCOPODIUM, or Club-moss, a genus of the natural order of musci, belonging to the cryptogamia class of plants. The antheræ are bivalved and sessile; there are no calyptra. There are 29 species, of which the following are the most remarkable: 1. The clavatum, or common club-moss, is common in dry and mountainous places, and in fir forests. The stalk is prostrate, branched, and creeping from a foot to two or three yards long; the radicles woody. The leaves are numerous, narrow, lanceolated, acute, often incurved at the extremity, terminated with a long white hair, and every where surround the stalk. The peduncles are erect, firm, and naked, (except being thinly set with lanceolet scales), and arise from the ends of the branches. They are generally two or three inches long, and terminated with two cylindrical yellowish spikes, imbricated with oval-acute scales, finely lacerated on the edges, and ending with a hair. In the ala or bosom of the scale is a kidney-shaped capsule, which bursts with elasticity when ripe, and throws out a light-yellow powder, which, blown into the flame of a candle, flashes with an explosion.

LYCOPSIS, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. The corolla has an incurvated tube. There are eight species, chiefly annuals.

LYCOPUS, a genus of the monogynia order, belonging to the diandria class of plants, and in the natural method ranking under the 42d order, verticillatæ. The corolla is quadrifid, with one of the segments emarginated; the stamina standing asunder, with four retuse seeds. There are three species, of which the water-horehound might probably be of use in dyeing.

LYGEUM, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the fourth order, gramina. The spatha or sheath is monophyllous; there are a pair of corollæ upon the same germen; the nut is bilocular. There is one species, a grass of Spain.

LYDIAN STONE, in mineralogy, is commonly intersected by veins of quartz. Fracture even, and sometimes inclining to conchoidal. Specific gravity 2.6 nearly. Powder black, or greyish black. This stone, or one similar to it, was used by the ancients as a touchstone. They drew the metal to be examined along the stone, and judged of its purity by the colour of the metallic streak. On this account it was called Βασανος, the trier. It was called the Lydian stone, as being found in the river Tmolus in Lydia.

LYMPH. See Anatomy, and Physiology.

LYNX. See Felis.

LYRE, Lyra, a musical instrument of the string kind, much used by the ancients.

LYRE, *lyra*, in astronomy, a constellation of the northern hemisphere, the number of whose stars, in Ptolemy's and Tycho's catalogues, are only 10, but 19 in the Britannic catalogue.

LYRIC. See Poetry.

LYSIMACHIA, *loosestrife*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 20th order, rotaceæ. The corolla is rotaceous; the capsule globular, beaked, and ten-valved. There are 12 species, but only four are commonly cultivated in gardens. These are hardy herbaceous perennials and biennials, rising with erect stalks from 18 inches to two or three feet high, and terminated by spikes and clusters of monopetalous, rotated, five-parted spreading flowers of white and yellow colours. The numulana, or yellow moneywort, or herb jevoperee, is particularly beautiful.

LYTHRUM, *purple loosestrife*, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. The calyx is cleft in 12 parts; and there are six petals inserted into it; the capsule is bilocular and polyspermous. There are 18 species, of which the most remarkable are. 1. The salicaria, or common purple loosestrife, with oblong leaves, is a native of Britain, and grows naturally by the sides of ditches and rivers. 2. The hispanum, or Spanish loosestrife, with a hyssop leaf, grows naturally in Spain and Portugal. The flowers are larger than those of the common sort, and make a fine appearance in the month of July, when they are in beauty.

M.

M, the twelfth letter of our alphabet. As a numeral it stands for mille, a thousand; and with a dash over it, thus $\overline{M}$, for a thousand times a thousand, or 1000000. Used as an abbreviature M. signifies Manlius, Marcus, Martius, Mucius; and M. Manius; M. B. mulier bona; Mag. Eq. magister equitum; Mag. Mil. magister militum; M. M. P. manu mancipio potestate; M. A. magister artium; MS. manuscript, and M. SS. manuscripts, in the plural. In the prescriptions of physicians, M. stands for manipulus, a handful; and sometimes for misce, or mixtura.

MABA, a genus of the triandria order, in the diœcia class of plants. The perianthium of the male is trifid; that of the female is as in the male; the fruit is a plum two-celled, superior. There is one species, a tree of the Friendly islands.

MABEA, a genus of the monoecia polyandria class and order. The calyx is one-leaved; corolla none. There are two species, called pipewood, shrubs of the West Indies.

MACARONIC, or Macaronian, an appellation given to a burlesque kind of poetry, made up of a jumble of words of different languages, and words of the vulgar tongue latinized.

MACE, the second coat or covering of the kernel of the nutmeg, is a thin and membranaceous substance, of an oleaginous nature and a yellowish colour; being met with in flakes of an inch an more in length, which are divided into a multitude of ramifications. It is of an extremely fragrant, aromatic, and agreeable flavour, and of a pleasant, but acrid and oleaginous taste. See Myristica.

MACERATION, in pharmacy, is an infusion of, or soaking ingredients in, water, or any other fluid, in order either to soften them or draw out their virtues.

MACHINE. See Mechanics.

MACKREL. See Scomber.

MACROCNEMON, a genus of the class and order pentandria monogynia. The cor. is bell-shaped; the capsule two-celled, two-valved; seeds imbricate. There are three species, small trees of the West Indies.

MACROLOBIUM, a genus of the class and order triandria monogynia. The calyx is double, pet. five, germ. pedicelled legume. There are three species, trees of Guiana.

MACULÆ, in astronomy, are dark spots appearing on the luminous surfaces of the sun and moon, and even some of the planets. The solar maculæ are dark spots of an irregular and changeable figure, observed in the face of the sun. These were first observed in November and December of the year 1610, by Galileo in Italy, and Harriot in England, unknown to, and independant of, each other, soon after they had made or procured telescopes.

There have been various observations made of the phenomena of the solar maculæ, and hypotheses invented for explaining them. Many of these maculæ appear to consist of heterogeneous parts; the darker and denser being called, by Hevelius, nuclei, which are encompassed as it were with atmospheres, somewhat rarer and less obscure; but the figure, both of the nuclei and entire maculæ, is variable. These maculæ are often subject to sudden mutations. In 1644, Hevelius observed a small thin macula, which in two days time grew to ten times it bulk, appearing also much darker, and having a larger nucleus: the nucleus began to fail sensibly before the spot disappeared; and before it quite vanished, it broke into four, which reunited again two days after. Some maculæ have lasted 2, 3, 10, 15, 20, 30, but seldom 40 days; though Kirchius observed one in 1681, that was visible from April 26th to the 17th of July. It is found that the spots move over the sun's disc with a motion somewhat slacker near the edge than in the middle parts; that they contract themselves near the limb, and in the middle appear larger; that they often run into one in the disc, though separated near the centre; that many of them first appear in the middle, and many disappear there; but that none of them deviate from their path near the horizon; whereas Hevelius, observing Mercury in the sun near the horizon, found him too low, being depressed 27″ beneath his former path.

From these phenomena are collected the following consequences:

1. That since Mercury's depression below his path arises from his parallax, the maculæ, having no parallax from the sun, are much nearer him than that planet.

2. That since they rise and disappear again in the middle of the sun's disc, and undergo various alterations with regard both to bulk, figure, and density, they must be formed de novo, and again dissolved about the sun; and hence some have inferred, that they are a kind of solar clouds, formed out of his exhalations; and if so, the sun must have an atmosphere.

3. Since the spots appear to move very regularly about the sun, it is hence inferred, that it is not that they really move, but that the sun revolves round his axis, and the spots accompany him, in the space of 27 days, 12 hours, 20 minutes.

4. Since the sun appears with a circular disc in every situation, his figure, as to sense, must be spherical.

The magnitude of the surface of a spot may be estimated by the time of its transit over a hair in a fixed telescope. Galileo estimates some spots as larger than both Asia and Africa put together; but if he had known more exactly the sun's parallax and distance, as they are known now, he would have found some of those spots much larger than the whole surface of the earth. For in 1612 he observed a spot so large as to be plainly visible to the naked eye, and therefore it subtended an angle of about a minute. But the earth, seen at the distance of the sun, would subtend an angle of only about 17″; therefore the diameter of the spot was to the diameter of the earth, as 60 to 17, or $3\frac{1}{2}$ to 1 nearly; and consequently the surface of the spot, if circular, to a great circle of the earth, as $12\frac{1}{4}$ to 1, and to the whole surface of the earth, as $12\frac{1}{4}$ to 4, or nearly 3 to 1. Gassendus observed a spot whose breadth was $\frac{1}{20}$ of the sun's diameter, and which therefore subtended an angle at the eye of above a minute and

a half, and consequently its surface was above seven times larger than the surface of the whole earth. He says he observed above forty spots at once, though without sensibly diminishing the light of the sun.

In the year 1779 there was a spot on the sun which was large enough to be seen by the naked eye. It was divided into two parts, and must have been 50,000 miles in diameter.

Various opinions have been formed concerning the nature, origin, and situation of the solar spots; but the most probable seems to be that of Dr. Wilson, professor of practical astronomy in the university of Glasgow. By attending particularly to the different phases presented by the umbra, or shady zone, of a spot of an extraordinary size that appeared on the sun, in the month of November 1769, during its progress over the solar disc, Dr. Wilson was led to form a new and singular conjecture on the nature of these appearances; which he afterwards greatly strengthened by repeated observations. The results of these observations are, that the solar maculæ are cavities in the body of the sun; that the nucleus, as the middle or dark part has usually been called, is the bottom of the excavations; and that the umbra, or shady zone surrounding it, is the shelving sides of the cavity. Dr. Wilson, besides having satisfactorily ascertained the reality of these immense excavations in the body of the sun, has also pointed out a method of measuring the depth of them. He estimates, in particular, that the nucleus or bottom of the large spot above-mentioned, was not less than a semidiameter of the earth, or about 4000 miles below the level of the sun's surface; while its other dimensions were of a much larger extent. He observed that a spot near the middle of the sun's disc is surrounded equally on all sides with its umbra; but that when, by its apparent motion over the sun's disc, it comes near the western limb, that part of the umbra which is next the sun's centre gradually diminishes in breadth, till near the edge of the limb it totally disappears; whilst the umbra on the other side of it is little or nothing altered. After a semi-revolution of the sun on his axis. if the spot appear again, it will be on the opposite side of the disc, or on the left hand. and the part of the umbra which had before disappeared is now plainly to be seen; while the umbra on the other side of the spot seems to have vanished in its turn, being hid from the view by the upper edge of the excavation, from the oblique position of its sloping sides with respect to the eye. But as the spot advances on the sun's disc, this umbra, or side of the cavity, comes in sight; at first appearing narrow. but afterwards gradually increasing in breadth, as the spot moves towards the middle of the disc. These appearances perfectly agree with the phases that are exhibited by an excavation in a spherical body, revolving on its axis; the bottom of the cavity being painted black, and the sides lightly shaded.

Dr. Herschel supposes that the spots in the sun are mountains on its surface, which considering the great attraction exerted by the sun upon bodies placed at its surface. and the slow revolution it has about its axis, he thinks may be more than 300 miles high. He says, that in August 1792 he examined the sun with several powers, from 90 to 500; and it appeared that the black spots are the opaque ground or body of the sun, and that the luminous part is an atmosphere which being broken, gives a glimpse of the sun itself.

MADDER. See Rubia.

MADNESS. See Medicine.

MADREPORA, in natural history, the name of a genus of submarine substances, the characters of which are, that they are almost of a stony hardness, resembling the corals, and are usually divided into branches, and pervious by many holes or cavities, which are frequently of a stellar figure.

In the Linnæan system, this is a genus of lithophyta: the animal that inhabits it is a medusa; it comprehends 39 species. According to Donati, the madrepora is like the coral as to its hardness, which is equal to bone or marble; the colour is white when polished; its surface is lightly wrinkled, and the wrinkles run lengthwise of the branches; in the centre there is a sort of cylinder, which is often pierced through its whole length by two or three holes. From this cylinder are detached about 17 laminæ, which run to the circumference in straight lines; and are transversely intersected by other laminæ, forming many irregular cavities; the cellules, which are composed of these laminæ ranged into a circle, are the habitations of litle polypes, which are extremely tender animals, generally transparent, and variegated with beautiful colours. M. de Peyssonel observes, that those writers who only considered the figures of submarine substances, denominated that class of them which seemed pierced with holes, pora; and those the holes of which were large they called madrepora. He defines them to be all those marine bodies which are of a stony substance, without either bark or crust, and which have but one apparent opening at each extremity, furnished with rays that proceed from the centre to the circumference. He observes that the body of the animal of the madrepora, whose flesh is so soft that it divides upon the gentlest touch, fills the centre; the head is placed in the middle, and surrounded by several feet or claws, which fill the intervals of the partitions observed in this substance, and are at pleasure brought to its head, and are furnished with yellow papillæ. He discovered that its head or centre was lifted up occasionally above the surface, and often contracted and dilated itself like the pupil of the eye: he saw all its claws moved, as well as its head or centre. When the animals of the madrepora are destroyed, its extremities become white. In the madrepora, he says, the animal occupies the extremity, and the substance is of a stony but more loose texture than the coral. This is formed, like other substances of the same nature, of a liquor which the animal discharges: and he father adds. that there are some species of the polype of the madrepora which are produced singly, and others in clusters. See Plate LXXXIV. Nat. Hit. figs. 256, 257; and Zoophytes.

MADREPORITE, a mineral found in the valley of Russback in Salzburg, and which obtained its name from its resemblance to madrepore. Colour in some parts black. in others dark-grey. Found in large round masses. Fracture even, passing to the conchoidal. Lustre greasy, passing to the silky. Brittle: moderately heavy. Streak grey; it is composed of

93.00 carbonat of lime
0.50 carbonate of magnesia
7.25 carbonat of iron

0.50 charcoal
4.50 silica in sand.

99.75

MADRIER, in the military art, a long and broad plank of wood, used for supporting the earth in mining and carrying on a sap, and in making coffers, caponiers, galleries, and for many other uses at a seige. Madriers are also used to cover the mouths of petards after they are loaded, and are fixed with the petards to the gates or places designed to be forced open.

MÆMACTERION, the fourth month of the Athenian year consisting of only 29 days, and answering to the latter part of September and the beginning of October.

MAGAZINE, a place in which stores are kept, or arms, ammunition, provisions, &c. Every fortified town ought to be furnished with a large magazine, which should contain stores of all kinds, sufficient to enable the garrison and inhabitants to hold out a long siege, and in which smiths, carpenters, wheel-wrights, bakers, &c. may be employed in making every thing belonging to the artillery, as carriages, waggons, &c.

Magazine, *powder*, is that place where the powder is kept in very large quantities. Authors differ greatly both in regard to situation and construction; but all agree, that they ought to be arched, and bomb-proof. In fortifications they are frequently placed in the rampart; but of late they have been built in different parts of the town. The first powder-magazines were made with Gothic arches; but M. Vauban, finding them too weak, constructed them in a semicular form, whose dimensions are 60 feet long within, 25 broad; the foundations are eight or nine feet thick, and eight feet high from the foundation to the spring of the arch; the floor is two feet from the ground, which keeps it from dampness.

An English engineer of great experience, some time since, had observed, that after the centres of semicircular arches are struck, they settle at the crown, and rise up at the haunches, even with a straight horizontal extrados; and still much more so in powder-magazines, whose outside at top is formed like the roof of a house, by two inclined planes joining in an angle over the top of the arch, to give a proper descent to the rain; which effects are exactly what might be expected agreeable to the true theory of arches. Now, as this shrinking of the arches must be attended with very ill consequences, by breaking the texture of the cement after it has been in some degree dried, and also by opening the joints of the voussoirs at one end, so a remedy is provided for this inconvenience, with regard to bridges, by the arch of equilibration in Dr. Hutton's book on bridges; but as the ill effect is much greater in powder-magazines, the same ingenious gentleman proposed to find an arch of equilibration for them also, and to construct it when the span is 20 feet, the pitch or height 10 (which are the same dimensions as the semicircle), the inclined exterior walls at top forming an angle of 113 degrees, and the height of their angular point above the top of the arch equal to seven feet.

MAGI, or Magians, an ancient religious sect in Persia, and other Eastern countries, who maintained, that there were two principles, the one the cause of all good, the other the cause of all evil; and abominating the adoration of all images, worshipped God only by fire, which they looked upon as the brightest and most glorious symbol of Oromasdes, or the good God: as darkness is the truest symbol of Arimanius, or the evil God. This religion was reformed by Zoroaster. The sect still subsists in Persia, under the denomination of gaurs.

MAGIC Lantern. See Optics.

Magic Square, in arithmetic, a square figure made up of numbers in arithmetical proportion, so disposed in parallel and equal ranks, that the sums of each row, taken either perpendicularly, horizontally, or diagonally, are equal: thus,

Natural square.

1	2	3
4	5	6
7	8	9

Magic square.

Magic squares seem to have been so called, from their being used in the construction of talismans.

MAGNA CHARTA, the great charter of the liberties of England, and the basis of their laws and privileges.

This charter may be said to derive its origin from king Edward the Confessor, who granted several privileges to the church and state, by charter; these liberties and privileges were also granted and confirmed by king Henry I., by a celebrated great charter now lost; but which was confirmed or re-enacted by king Henry II. and king John. Henry III., the successor of this last prince, after having caused twelve men to make inquiry into the liberties of England in the reign of Henry I., granted a new charter, which was the same as the present Magna Charta; this he several times confirmed, and as often broke; till in the thirty-seventh year of his reign, he went to Westminster-hall, and there, in the presence of the nobility and bishops, who held lighted candles in their hands, Magna Charta was read, the king all the while holding his hand to his breast, and at last solemnly swearing faithfully and inviolably to observe all the things therein contained, &c.; then the bishops extinguishing the candles, and throwing them on the ground, cried out, "Thus let him be extinguished, and stink in hell, who violates this charter." It is observed, that notwitstanding the solemnity of this confirmation, king Henry, the very next year, again invaded the rights of his people, till the barons entered into a war against him; when, after various success, he confirmed this charter, and the charter of the forest, in the fifty-second year of his reign. This excellent charter, so equitable and beneficial to the subject, is the most ancient written law in the kingdom: by the 25 Edw. I. it is ordained, that it shall be taken as the common law; and by the 43 Edw. III. all statutes made against it are declared to be void.

MAGNESIA. About the beginning of the eighteenth century, a Roman canon exposed a white powder to sale at Rome as a cure for all diseases. This powder he called magnesia alba. He kept the manner of preparing it a profound secret; but in 1707 Valentini informed the public that it might be obtained by calcining the lixivium which remains after the preparation of nitre: and two years after, Slevogt discovered that it might be precipitated by potass from the mother-ley of nitre. This powder was generally supposed to be lime, till Frederic Hoff-

man observed that it formed very different combinations with other bodies. But little was known concerning its nature, and it was even confounded with lime by most chemists, till Dr. Black made his celebrated experiments on it in 1755. Margraff published a dissertation on it in 1759, and Bergman another in 1775, in which he collected the observations of these two philosophers, and which he enriched also with many additions of his own. Butini of Geneva likewise published a valuable dissertation on it in 1779.

As magnesia has never yet been found native in a state of purity, it may be prepared in the following manner: sulphat of magnesia, a salt composed of this earth and sulphuric acid, exists in sea-water, and in many springs, particularly in some about Epsom; from which circumstance it was formerly called Epsom salt. This salt is to be dissolved in water, and half its weight of potass added. The magnesia is immediately precipitated, because potass has a stronger affinity for sulphuric acid. It is then to be washed with a sufficient quantity of water, and dried.

Magnesia thus obtained is a very soft white powder, which has very little taste, and is totally destitute of smell. Its specific gravity is about 2.3. It converts delicate vegetable blues (paper for instance, stained with the petals of the mallow) to green.

It is not melted by the strongest heat which it has been possible to apply; but M. Darcet observed that, in a very high temperature, it became somewhat agglutinated. When formed into a cake with water, and then exposed to a violent heat, the water is gradually driven off, and the magnesia contracts in its dimension; at the same time it acquires the property of shining in the dark when rubbed upon a hot iron plate.

It is almost insoluble in water; for, according to Mr. Kirwan, it requires 7900 times its weight of water at the temperature of 60° to dissolve it. It is capable, however, of combining with water in a solid state; for 100 parts of magnesia, thrown into water, and then dried, are increased in weight to 118 parts. Even when combined with carbonic acid (for which it has a strong affinity) it is capable of absorbing and retaining $1\frac{1}{2}$ times its own weight of water without letting go a drop; but on exposure to the air, this water evaporates, though more slowly than it would from lime.

Magnesia has never yet been obtained in a crystallized form.

When exposed to the air, it attracts carbonic acid gas and water; but exceedingly slowly. Butini left a quantity of it for two years in a porcelain cup merely covered with paper; its weight was only increased $\frac{1}{144}$ part.

Magnesia does not combine with oxygen; nor is it altered by any of the compounds into which oxygen enters. The only one of the simple combustibles with which it can be united is sulphur. No person has hitherto succeeded in forming a phosphuret of magnesia. The sulphuret of magnesia may be formed by exposing a mixture of two parts of magnesia and one part of sulphur, to a gentle heat in a crucible. The result is a yellow powder, slightly agglutinated, which emits very little sulphureted hydrogen gas, when thrown into water. A moderate heat is sufficient to drive off the sulphur.

Magnesia does not combine with azote, but it unites with muriatic acid, and forms a compound called muriat of magnesia. It has no action upon the metals: nor does it combine, as far as is known at present, with the metallic oxides, unless some intermediate substance is present. It does not combine with the fixed alkalies, neither are its properties altered by these bodies; but it has a strong propensity to enter into triple compounds with ammonia.

There seems to be little affinity between magnesia and barytes; at least no mixture of the two earths is fusible in the strongest heat which it has been possible to apply.

Mr. Kirwan has shown that there is but little affinity between strontian and magnesia. They do not melt when exposed to a strong heat, at least when the strontian exceeds or equals the magnesia.

Equal parts of lime and magnesia, mixed together, and exposed by Lavoisier to a very violent heat, did not melt; neither did they melt when Mr. Kirwan placed them in the temperature of 150° Wedgewood.

The affinities of magnesia, according to Bergman, are as follows:

Oxalic acid,	Tartaric,
Phosphoric,	Citric,
Sulphuric,	Lactic,
Fluoric,	Benzoic,
Arsenic,	Acetic,
Saclactic,	Boracic,
Succinic,	Sulphurous,
Nitric,	Carbonic,
Muriatic,	Prussic.

Magnesia is used in medicine, to remove acidities.

MAGNETISM. The natural magnet, or loadstone, is a hard mineral body of a dark brown, or almost black colour, and when examined, is found to be an ore of iron. It is met with in various countries, generally in iron mines, and of all sizes and forms.

This singular substance was known to the ancients; and they had remarked its peculiar property of attracting iron, though it does not appear that they were acquainted with the wonderful property which it also has, of turning to the pole when suspended, and left at liberty to move freely.

Upon this remarkable circumstance the mariner's compass depends, an instrument which gives us such infinite advantages over the ancients. It is this which enables the mariners to conduct their vessels through vast oceans out of the sight of land, in any given direction: and this directive property also guides the miners in their subterranean excavations, and the traveller through desarts otherwise impassable.

It is not precisely known when and by whom this directive property of the magnet was discovered. The most probable accounts seem to prove, that it was known early in the 13th century; and that the person who first made mariner's compasses, at least in Europe, was a Neapolitan of the name of Flavio, or John de Gioga, or Giova, or Gira.

The natural loadstone has also the quality of communicating its properties to iron and steel; and when pieces of steel properly prepared are touched, as it is called, by the loadstone, they are denominated artificial magnets.

These artificial magnets are even capable of being

made more powerful than the natural ones; and as they can be made of any form, and are more convenient, they are now universally used, so that the loadstone or natural magnet is only kept as a curiosity.

All magnets, whether natural or artificial, are distinguished from other bodies by the following characteristics, which appear to be inseparable from their nature; so that no body can be called a magnet, unless it is possessed of all these properties:

1. A magnet attracts iron.

2. When a magnet is placed so as to be at liberty to move freely in every direction, its ends point towards the poles of the earth, or very nearly so; and each end always points to the same pole. This is called the polarity of the magnet; the ends of the magnet are called poles; and they are called north and south poles of the magnet, according as they point to the north or south pole of the earth. When a magnet places itself in this direction, it is said to traverse.

3. When the north pole of one magnet is presented to the south of another magnet, these ends attract each other; but if the south pole of one magnet is presented to the south pole of another, or the north pole of one to the north pole of another, these ends will repel each other.

From these criteria, it is easy to determine the names of the poles of a magnetical bar, by applying it near a suspended magnet whose poles are known.

4. When a magnet is situated so as to be at liberty to move itself with sufficient freedom, its two poles do not lie in a horizontal direction, but it generally inclines one of them towards the horizon, and of course it elevates the other pole above it. This is called the inclination or dipping of the magnet.

5. Any magnets may, by proper methods, be made to impart those properties to iron or steel.

A plane perpendicular to the horizon, and passing through the poles of a magnet when standing in their natural direction, is called the magnetic meridian; and the angle which the magnetic meridian makes with the meridian of the plane where the magnet stands, is called the declination of the magnet at that place.

Of magnetic attraction and repulsion.—When a piece of iron is brought within a certain distance of one of the poles of a magnet, it is attracted by it; and if the iron is at liberty to move, it adheres to the magnet, and cannot be separated without some force. It appears at first sight, that the attraction lies only in the magnet, but experiment proves this attraction to be mutual; the iron attracting the magnet as much as the magnet attracts the iron. Place the magnet and the iron upon two separate pieces of cork, or wood, floating upon water, at a little distance from each other, and it will be found that the iron moves towards the magnet, as well as the magnet towards the iron; but if the iron is kept steady, the magnet will move towards it.

This attraction is strongest at the poles of a magnet, and diminishes in proportion to the distance of any part from the poles, so that in the middle between the poles there is no attraction. This may be easily perceived by presenting a piece of iron to various parts of the surface of a magnet.

The intensity of the attractive power diminishes also, according to the distance from the magnet. If the magnet and iron touch each other, it requires a certain degree of force to separate them; if the iron is removed a little way from the magnet, an attraction will be plainly perceived, but not so powerful; and by increasing this distance the attraction will be much diminished.

The law of diminution of this attraction is not yet known. Some have imagined that it diminishes in proportion to the square of the distance, others as the cube of the distance. But either from the difficulty of the subject, on account of the experiments having been made without sufficient accuracy, the question remains yet undecided; it is only known that the attractive force decreases faster than the simple ratio of the distances.

As magnetic attraction takes place only between poles of different names of different magnets; that is, the north pole of one magnet attracts the south pole of another; consequently magnetic repulsion acts only between poles of the same name of different magnets. Thus, if the north pole of one magnet is opposed to the north pole of another magnet, or if the south pole be opposed to the south pole of the other, then those magnets will repel each other, and that nearly with as much force as the poles of different names would attract each other.

But it frequently happens, that though magnets are placed with the same poles towards each other, yet they either attract each other, or show a perfect indifference. This, at first, seems to contradict the above-mentioned general law; but this difficulty is removed by the following considerations:

When a piece of iron is brought within a certain distance of a magnet, it becomes, in fact, itself a magnet, having the polarity, the attractive and repulsive properties for other iron, &c.; that part of it which is nearest to the south pole of the magnet, becoming a north pole, and the opposite part a south pole, or vice versa, according to the end of the magnet presented. Thus if A B, Plate LXXX. Magnetism, fig. 1, be an oblong piece of iron, and be brought near the north pole N of the magnet NS, then this piece of iron while standing within the magnet's sphere of action, will have all the properties of a real magnet, and its end A will be found to be a south pole, while the end B is a north pole.

Soft iron, when placed within the influence of a magnet, easily acquires these properties; but they last only while the iron remains in that situation, and when it is removed its magnetism vanishes immediately. But with iron containing carbon, and particularly with steel, the case is very different; and the harder the iron or the steel is, the more permanent is the magnetism which it acquires from the influence of a magnet; but it will be in the same proportion more difficult to render it magnetic.

If a piece of soft iron, and a piece of hard steel, both of the same shape and size, are brought within the influence of a magnet at the same distance, it will be found that the iron is attracted more forcibly, and appears more powerfully magnetic than the steel; but if the magnet is removed, the soft iron will instantly lose its acquired properties, whereas the hard steel will preserve them for a long time, having become an artificial magnet.

Neither the magnetic attraction nor repulsion is in the least diminished, or at all affected, by the interposition

of any sort of bodies, except iron, or such bodies as contain iron.

The properties of the magnet are not affected either by the presence or by the absence of air. Heat weakens the power of a magnet, and subsequent cooling restores it, but not quite to its former degree. A white heat destroys it entirely, or very nearly so; and hence it appears, that the powers of magnets must be varying continually. Cavallo observes, that iron in a full red heat, or white heat, is not attracted by the magnet; but the attraction commences as soon as the redness begins to appear.

The attractive power of a magnet may be considerably improved by suspending a weight of iron to it by its power of attraction, which may be gradually increased; and also by keeping it in a proper situation, viz. with its north pole towards the north, and its south pole, consequently, towards the south. On the contrary, this power is diminished by an improper situation, and by keeping too small a piece of iron, or no iron at all, appended to it.

In these northern parts of the world, the north pole of a magnet has more power than its south pole; whereas, the contrary effect has been said to take place in the southern parts.

Amongst the natural magnets, the smallest generally possess a greater attractive power in proportion to their size than those of a larger size.

It frequently happens, that a natural magnet, cut off from a larger loadstone, will be able to lift a greater weight of iron than the original loadstone itself.

As both magnetic poles together attract a much greatweight than a single pole; and as the two poles of a magnet generally are in opposite parts of its surface, in which case it is almost impossible to adapt the same piece of iron to them both at the same time; therefore it has been commonly practised to adapt two broad pieces of soft iron to the poles of the stone, and to let them project on one side of the stone; for those pieces become themselves magnetic while thus situated, and to them the piece of iron or weight may be easily adapted. Those two pieces of iron are generally fastened upon the stone by means of a brass or silver box. The magnet in this case is said to be armed, and the two pieces of iron are called the armature.

Fig. 2. represents an armed magnet, where A B is the loadstone: C D, C D, are the armature, or the two pieces of soft iron, to the projections of which D D the iron weight F is to be applied. The dots E C D C D represent the brass box, with a ring at E, by which the armed magnet may be suspended.

Artificial magnets, when straight, are sometimes armed in the same manner; but they are frequently made in the shape of a horse-shoe, having their poles at the truncated extremities, as at N and S, fig. 3, in which shape it is evident that they want no armature.

Most probably the magnet attracts iron only; but when it is considered how universally iron is dispersed throughout nature, it is evident that a vast number of bodies must on that account be attracted by the magnet more or less forcibly, in proportion to the quantity and quality of the iron they contain. Indeed, it is wonderful to observe what a small portion of iron will render a body subject to the influence of the magnet.

The polarity of the magnet.—Every magnet has a south and a north pole, which are at opposite ends; and a line drawn from one end to the other, passes through the centre of the magnet. Here it must not be understood, that the polarity of a magnet resides only in two points of its surface; for in reality, it is the one half of the magnet that is possessed of one kind of polarity, and the other half of the other kind of polarity; the poles, then, are those points in which that power is the strongest.

The line drawn from pole to the other, is called the axis of the magnet; and a line formed all round the surface of the magnet, by a plane which divides the axis into two equal parts, and is perpendicular to it, is called the equator of the magnet.

It is the polarity of the magnet that renders it so useful to navigators. When a magnet is kept suspended freely, so that it may turn north and south, the pilot, by looking at the position of it, can steer his course in any required direction. Thus, if a vessel is steered towards a certain place which lies exactly westward of that from which it set out, the navigator must direct it so, that its course may be always at right angles with the direction of the magnetic needle of his compass, keeping the north end of the magnet on the right-hand side, and of course, the the south end on the left-hand side of the vessel; for as the needle points north and south, and the direction is east and west, the intended course of the vessel is exactly perpendicular to the position of the magnet. A little reflection will show how the vessel may be steered in any other direction.

An artificial magnet fitted up in a proper box, for the purpose of guiding the direction of a traveller, is called a magnetic needle, and the whole together is called the mariner's compass.

Although the north pole of the magnet in every part of the world, when suspended, points towards the northern parts, and the south pole towards the southern parts, yet its ends seldom point exactly towards the poles of the earth. The angle in which it deviates from due north and south, is called the angle of declination, or the declination of the magnetic needle, or the variation of the compass; and this declination is said to be east or west, according as the north pole of the needle is eastward or westward of the astronomical meridian of the place.

This deviation from the meridian is not the same in all parts of the world, but is different in different places, and it is even continually varying in the same place. For instance, this declination is not the same in London as at Paris, or as in India; and the declination in London, or in any other place, is not the same at this time as it was some years ago. This declination from the meridian is so variably, that it may be observed to change, even in one or two hours time; and this is not owing to the construction of the magnetic needle; for in the same place, and at the same time, all true magnetic needles point the same way.

The declination from the meridian, and the variation of this in different parts of the world, are very uncertain, and cannot be foretold; actual trial is the only method of ascertaining them. This circumstance forms a great impediment to the improvement of navigation. It is true,

that great pains have been taken by navigators and other observers, to ascertain the declination in various parts of the world, and such declinations have been marked in maps, charts, books, &c.; but still, on account of the constant change to which this variation is liable, these can only serve for a few years; nor has the law of this variation or fluctuation been yet discovered, though various hypotheses have been formed for that purpose. When the variation was first observed, the north pole of the magnetic needle declined eastward of the meridian of London; but it has since that time been changing continually towards the west; so that in the year 1657 the magnetic needle pointed due north and south. At present, it declines about $24\frac{1}{2}''$ westward, and it seems to be still advancing towards the west.

Before volcanic eruptions and earthquakes, the magnetic needle is often subject to very extraordinary movements.

It is also agitated before and after the appearance of the aurora borealis.

The magnetic inclination or dip of the needle.—If a needle which is accurately balanced, and suspended so as to turn freely in a vertical plane, is rendered magnetical, the north pole will be depressed, and the south pole elevated above the horizon: this property is called the inclination, or dip of the needle, and was discovered by Robert Norman, about the year 1576.

Take a globular magnet, or, which is more easily procured, an oblong one, like SN, fig. 4; the extremity N of which is the north pole, the other extremity S is the south pole, and A is its middle or equator; place it horizontally upon a table CD: then take another small oblong magnet *ns* (viz. a bit of steel wire, or a small sewing-needle magnetized) and suspend it by means of a fine thread tied to its middle, so as to remain in an horizontal position, when not disturbed by the vicinity of iron, or other magnet. Now if the same small magnet, being held by the upper part of the thread, be brought just over the middle of the large magnet, within two or three inches of it, the former will turn its south pole *s*, towards the north pole, N, of the large magnet; and its north pole *n*, towards the south pole, S, of the large one. It will be farther observed, that the small magnet, whilst kept just over the middle A of the large one, will remain parallel to it; for since the poles of the small magnet are equally distant from the contrary poles of the large magnet, they are equally attracted. But if the small magnet be moved a little nearer to one end than to the other of the large magnet, then one of its poles, namely, that which is nearest to the contrary pole of the large magnet, will be inclined downwards, and of course the other pole will be elevated above the horizon. It is evident that this inclination must increase according as the small magnet is placed nearer to one of the poles of the large one; because the attraction of the nearest pole will have more power upon it. If the small magnet be brought just opposite to one of the poles of the large magnet, it will turn the contrary pole towards it; and will place itself in the same straight line with the axis of the large magnet.

This simple experiment will enable the reader to comprehend easily the phenomena of the magnetic inclination, or of the dipping needle, upon the surface of the earth; for it is only necessary to imagine that the earth is a large magnetic (as in fact it appears to be), and that any magnet, or magnetic needle, commonly used, is the small magnet employed in the above-mentioned experiment; for, supposing that the north pole of the earth is possessed of a south magnetic polarity, and that the opposite pole is possessed of a north magnetic polarity, it appears evident, and it is confirmed by actual experience, that when a magnet, or magnetic needle, properly shaped and suspended, is kept near the equator of the earth (since neither the magnetic equator nor the magnetic poles of the earth, coincide with its real equator and poles), it must remain in a horizontal situation: if the magnet is removed nearer to one of the magnetic poles of the earth, it must incline to one of its extremities, namely, that which is possessed of the contrary polarity; and this inclination must increase in proportion as the needle recedes from the magnetic equator of the earth. Lastly, when the needle is brought exactly over one of the magnetic poles of the earth, it must stand perpendicular to the horizon of that place.

A magnetic needle constructed for the purpose of showing this property, is called a dipping-needle, and its direction in any place is called the magnetical line. When it was said, that the north pole of the earth possessed south polarity, it was only meant that it had a polarity contrary to that end of the magnetic needle which is directed towards it.

If the geographical poles of the earth (that is, the ends of its axis), coincided with its magnetic poles; or even if the magnetic poles were constantly at the same distance from them; the inclination of the needle, as well as its declination, would always be the same; and hence, by observing the direction of the magnetic needle in any particular place, the latitude and longitude of that place might be ascertained; but this is not the case, for the magnetic poles of the earth do not coincide with its real poles, and they are also certainly shifting their situation; hence the magnetic needle changes continually and irregularly, not only in its horizontal direction, but likewise in its inclination, according as it is removed from one place to another, and also while it remains in the very same place.

This change of the dip in the same place, however, is very small. In London, about 1576, the north pole of the dipping needle stood 71° 50′ below the horizon; and in 1775, it stood at 72° 3′; the whole change of inclination, during so many years, amounting to less than a quarter of a degree.

There are various methods of giving the magnetic property to steel or iron. In some cases, it appears to be acquired without the use of another magnet.

If you take a bar of iron three or four feet long, and hold it in a vertical position, you will find that the bar is magnetic, and will act upon another magnet; the lower extremity of the bar attracting the south pole, and repelling the north pole. If you invert the bar, the polarity will be instantly reversed; the extremity which is now lowest, will be found to be a north pole, and the other extremity will be a south pole.

A bar of hard iron, or steel, will not answer for the above experiment, the magnetism of the earth not being sufficient to magnetise it.

Bars of iron that have stood in a perpendicular position,

are generally found to be magnetical; as fire-irons, bars of windows, &c.

If a long piece of hard iron is made red-hot, and then left to cool in the direction of the magnetical line, it becomes magnetical.

Striking an iron bar with a hammer, or rubbing it with a file, while held in this direction, likewise renders it magnetical. An electric shock produces the same effect; and lightning often renders iron magnetic.

A magnet cannot communicate a degree of magnetism stronger than that which itself possesses; but two or more magnets, joined together, may communicate a greater power to a piece of steel, than either of them possesses singly: hence we have a method of constructing very powerful magnets, by first constructing several weak artificial magnets, and then joining them together to form a compound magnet, and to act more powerfully upon a piece of steel.

1. Place two magnetic bars, A, B, fig. 5. in a line with the north, or marked end of one, opposed to the south, or unmarked end of the other; but at such a distance from each other, that the magnet to be touched may rest with its marked end on the unmarked end of A, and its unmarked end on the marked end of B; then apply the north end of the magnet E, and the south end of D, to the middle of the bar C, the opposite ends being elevated as in the figure; draw E and D asunder along the bar C, one towards A, the other towards B, preserving the same elevation; remove E and D a foot or two from the bar when they are off the ends, then bring the north and south poles of these magnets together, and apply them again to the middle of the bar C as before: repeat the same process five or six times, then turn the bar, and touch the opposite surface in the same manner, and afterwards the two remaining surfaces; by this means the bar will acquire a strong fixed magnetism.

2. Place the two bars which are to be touched parallel to each other; and then unite the ends by two pieces of soft iron, called supporters, in order to preserve, during the operation, the circulation of the magnetic matter; the bars are to be placed so that the marked end D (fig. 6), may be opposite the unmarked end B; then place the two attracting poles G and I on the middle of one of the bars to be touched, raising the ends so that the bars may form an obtuse angle of 100 or 120 degrees; the ends G and I of the bars are to be separated two or three tenths of an inch from each other. Keeping the bars in this position, move them slowly over the bar AB, from one end to the other, going from end to end about fifteen times. Having done this, change the poles of the bars (*i. e.* the marked end of one is always to be against the unmarked end of the other), and repeat the same operation on the bar CD, and then on the opposite faces of the bars. The touch thus communicated may be further increased, by rubbing the different faces of the bars with sets of magnetic bars, disposed as in fig. 7.

In these operations all the pieces should be well polished, the sides and ends made quite flat, and the angels quite square.

A magnet bent so that the two ends almost meet, is called a horse-shoe magnet, fig. 3. To rendar it magnetic, place a pair of magnetic bars against the ends of the horse-shoe, with the south end of the bar against that of the horse-shoe which is intended to be the north, and the north end of the bar to that which is to be the south; the contact, or lifter of soft iron, to be placed at the other end of the bars. Also rub the surfaces of the horse-shoe with a pair of bars placed in the form of a compass, or with another horse-shoe magnet, turning the poles properly to the poles of he horse-shoe magnet; being careful that these bars never touch the ends of the straight bars. If the bars are separated suddenly from the horse-shoe magnet, its force will be considerably diminished; to prevent this, slip on the lifter, or support, to the end of the horse-shoe magnet, but in such a manner, however, that it may not touch the bars; the bars may then be taken away, and the support slid to its place.

Magnetism is best communicated to compass-needles by the two following methods:

Procure a pair of magnetic bars, not less than six inches in length. Fasten the needle down on a board, and with a magnet in each hand draw them from the centre upon the needle outwards; then raise the bars to a considerable distance from the needle, and bring them perpendicularly down upon the centre, and draw them over again. This operation repeated about twenty times will magnetize the needle, and its ends will point to the poles contrary to those that touched them.

Over one end of a combined horse-shoe magnet, of at least two in number, and six inches in length, draw from its centre that half of the needle which is to have the contrary pole to the end of the magnet: raise the needle to a considerable distance, and draw it over the magnet again; this repeated about twenty times at least, and the same for the other half, will sufficiently communicate the power.

A set of bars are exceedingly useful for magnetizing other bars, or needles of compasses, &c. their power may also be increased when lost or impaired by mismanagement, &c. A set of such bars, viz. six bars and the two iron conductors, may be preserved in a box; taking care to place the north pole of one contiguous to the south pole of the next, and that contiguous to the north pole of the third, &c. as shown in fig. 8.

After what has been said above, we need not describe how a knife, or any other piece of steel, &c. may be rendered magnetic, or in what manner a weak magnet may be rendered more powerful. But it may perhaps be necessary to say something concerning the communication of magnetism to crooked bars like ABC, fig. 9.

Place the crooked bar flat upon a table, and to its extremities apply the magnetic bars DF, EG; joining their extremities FG, with the conductor or piece of soft iron FG; then to its middle apply the magnetic bars placed at an angle: or you may use two bars only, placed as shown in fig. 9, and stroke the crooked bar with them from end to end, following the direction of that bent bar; so that on one side of it the magnetic bars may stand in the direction of the dotted representation LK. In this manner, when the piece of steel ABC has been rubbed a sufficient number of times on one side, it must be turned with the other side upwards, &c.

In communicating magnetism, it is best to use weak magnets first, and those that are stronger afterwards; but you must be very careful not to use weak after strong magnets.

A magnet loses nothing of its own power by communicating to other substances, but is rather improved.

Every kind of violent percussion weakens the power of a magnet. A strong magnet has been entirely deprived of its virtue, by receiving several smart strokes of a hammer; indeed, whatever deranges or disturbs the internal pores of a magnet will injure its magnetic force.

Fill a small dry glass tube with iron filings, press them in rather close, and then touch the tube as if it was a steel bar, and the tube will attract a light needle; shake the tube, so that the situation of the filings may be disturbed, and the magnetic virtue will vanish.

Magnets should never be left with two north or two south poles together; for when they are thus placed, they diminish and destroy each other's power. Magnetic bars should therefore be always left with the opposite poles laid against each other, or by connecting their opposite poles by a bar of iron. The power of a magnet is increased by letting a piece of iron remain attached to one or both of its poles. A single magnet should therefore be always thus left.

The difference of steel in receiving magnetism is very great, as is easily proved by touching in the same manner, and with the same bars, two pieces of steel of equal size, but of different kinds. With some sort of steel, a few strokes are sufficient to impart to them all the power they are capable of receiving; other sorts require a longer operation; sometimes it is impossible to give them more than a small degree of magnetism.

A piece of spring-tempered steel will not retain as much magnetism as hard steel; soft steel still less, and iron retains scarcely any. Iron when oxydated loses its magnetism.

The construction and the use of the principal magnetical instruments. &c.—The magnetical instruments may be reduced to three principal heads; viz. 1st. the magnets or magnetic bars, which are necessary to magnetize needles of compasses, or such pieces of steel, iron, &c. as may be necessary for divers experiments; and which have already been sufficiently explained in the preceding pages: 2dly, the compasses, such as are used in navigation, and for other purposes, which are only magnetic needles justly suspended in boxes, and which, according to the purposes for which they are particularly employed, have several appendages, or differ in size, and in accuracy of divisions, &c. whence they derive the different names of pocket compasses, steering compasses, variation compasses, and azimuth compasses: and 3dly, the dipping needle.

The magnetic needles which are commonly used at sea, are between four and six inches long; but those which are used for observing the daily variation, are made a little longer, and their extremities point the variation upon an arch or circle properly divided and affixed to the box.

The best shape of a magnetic needle is represented in figs. 10 and 11; the first of which shows the upper side, and the second shows a lateral view of the needle, which is of steel, having a pretty large hole in the middle, to which a conical piece of agate is adapted by means of a brass piece O, into which the agate-cap (as it is called) is fastened. Then the apex of this hollow cap rests upon the point of a pin F, which is fixed in the centre of the box, and upon which the needle, being properly balanced, turns very nimbly. For common purposes, those needles have a conical perforation made in the steel itself, or in a piece of brass which is fastened in the middle of the needle.

A mariner's compass. or compass generally used on board of ships, is represented in fig. 12. The box, which contains the card or fly with the needle, is made of a circular form, and either of wood, or brass, or copper. It is suspended within a square wooden box, by means of two concentric circles, called gimbalds, so fixed by cross axes *a, a, a, a,* to the two boxes (see the plan, fig. 13), that the inner one, or compass-box, shall retain a horizontal position in all motions of the ship, whilst the outer or square box is fixed with respect to the ship. The compass box is covered with a pane of glass, in order that the motion of the card may not be disturbed by the wind. What is called the card (fig. 14), is a circular piece of paper, which is fastened upon the needle, and moves with it. Sometimes there is a slender rim of brass, which is fastened to the extremities of the needle, and serves to keep the card stretched. The outer edge of this card is divided into 360 equal parts or degrees, and within the circle of those divisions it is again divided into 32 equal parts, or arcs, which are called the points of the compass, or rhumbs, each of which is often subdivided into quarters. The initial letters N, NE, &c. are annexed to those rhumbs, to denote the north, north-east, &c. The middlemost part of the card is generally painted with a sort of star, whose ray terminate in the above-mentioned divisions. To avoid confusion those letters, &c. are not drawn in the figure.

The azimuth compass is nothing more than the above-mentioned compass, to which two sights are adapted, through which the sun is to be seen, in order to find its azimuth, and from thence to ascertain the declination of the magnetic needle at the place of observation; see fig. 15. The particulars in which it differs from the usual compass, are the sights F, G; in one of which, G, there is an oblong aperture with a perpendicular thread or wire stretched through its middle; and in the other sight F, there is a narrow perpendicular slit. The thread or wire HI is stretched from one edge of the box to the opposite. The ring AB of the gimbalds rests with its pivots on the semicircle CD, the foot E of which turns in a socket, so that whilst the box KLM is kept steady, the compass may be turned round, in order to place the sights F, G, in the direction of the sun.

The pivots of the gimbalds of this, as well as of the common sort of compasses, should lie in the same plane with the point of suspension of the needle, in order to avoid as much as possible the irregularity of the vibrations.

There are, on the inside of the box, two lines drawn perpendicularly along the sides of the box, just from the points where the thread HI touches the edge of the box. These lines serve to show how many degrees the north or south pole of the needle is distant from the azimuth of the sun; for which purpose, the middle of the apertures of the sights F, G, the thread HI, and the said lines, must be exactly in the same vertical plane. The use of the thread HI. which is often omitted in instruments of this sort, is likewise to show the degrees between the

magnetic meridian and the azimuth; when the eye of the observer stands perpendicularly over it. On the side of the box of this sort of compasses, there generally is a nut or stop, which, when pushed in, bears against the card and stops it, in order that the divisions of the card which coincide with the lines in the box, may be more commodiously read off.

The dipping-needle, though of late much improved, is however still far from perfection. The general mode of constructing it is to pass an axis quite through the needle, to let the extremities of this axis, like those of the beam of a balance, rest upon its supports, so that the needle may move itself vertically round, and when situated in the magnetic meridian, it may place itself in the magnetic line. The degrees of inclination are shown upon a divided circle, in the centre of which the needle is suspended. Fig. 16 represents a dipping-needle of the simplest construction; AB is the needle, the axis of which FE rests upon the middle of two lateral bars CD, CD, which are made fast to the frame that contains the divided circle AIBK. This machine is fixed on a stand G; but, when used at sea, it is suspended by a ring H, so as to hang perpendicularly. When the instrument is furnished with a stand, a spirit-level O is generally annexed to it, and the stand has three screws, by which the instrument is situated so that the centre of the motion of the needle, and the division of 90° on the lower part of the divided circle, may be exactly in the same line, perperdicular to the horizon. See Level.

The few experiments which follow, are principally intended to illustrate the theory.

Ex. 1. The method of discovering whether a body is attractable by the magnet or not, and whether it has any polarity or not, or which is its south, and which is its north pole, is so easily performed as not to require many words; for by approaching a magnet to the body in question (which, if necessary, may be set to swim upon water), or by presenting the body in question to either ex-extremity of a suspended magnetic needle, the desired object may be obtained.

Ex. 2. Tie two pieces of soft iron wire, AB, AB, fig. 17 and 18, each to a separate thread, AC, AC, which join at top, and forming them into a loop, suspend them so as to hang freely. Then bring the marked end D fig. 19, which is the north, of a magnetic bar just under them, and the wires will immediately repel each other, as shown in fig. 18; and this divergency will increase to a certain limit; according as the magnet is brought nearer, and vice versa. The reason of this phenomenon is, that by the action of the north magnetic pole D, both the extremities B, B, of the wires, acquire the same, viz. the south polarity; consequently they repel each other; and the extremities, A, A, acquire the north polarity, in consequence of which they also repel each other.

If instead of the north pole D, you present the south pole of the magnetic bar, the repulsion will take place as before; but now the extremities B, B, acquire the north, and the extremities A, A, acquire the south polarity.

On removing the magnet, the wires, if of soft iron, will soon collapse, having lost all their magnetic power; but if steel wires, or common sewing needles be used, they will continue to repel each other after the removal of the magnet; the magnetic power being retained by steel.

Ex. 3. Lay a sheet of paper flat upon a table, strew some iron filings upon the paper, place a small magnet among them; then give a few gentle knocks to the table, so as to shake the filings, and you will find that they dispose themselves about the magnet NS, as shown in fig. 20; the particles of iron clinging to one another, and forming themselves into lines, which at the very poles N, S, are in the same direction with the axis of the magnet; a little sideway of the poles they begin to bend, and then they form complete arches, reaching from some point in the northern half of the magnet, to some other point in the southern half.

Ex. 4. Place a magnetic bar AB, fig. 21, so that one of its poles may project a short way beyond the table, and apply an iron weight C to it; then take another magnetic bar, DE, like the former, and bring it parallel to, and just over the other, at a little distance, and with the contrary poles towards each other; in consequence of which the attraction of B will be diminished, and the iron C, if sufficiently heavy, will drop off, the magnet AB being then only able to support a smaller piece of iron. By bringing the magnets still nearer to each other, the attraction of B will be diminished still farther; and, when the two magnets come quite into contact (provided they are equal in power), the attraction between B and C will vanish entirely; but if the experiment be repeated with this difference, viz. that the homologous poles of the magnets be brought towards each other, then the attraction between B and C, instead of being diminished, will be increased.

MAGNITUDE, whatever is made up of parts locally extended, or that has several dimensions; as a line, surface, solid, &c. The apparent magnitude of a body is that measured by the visual angle, formed by rays drawn from the extremes to the centre of the eye; so that whatever things are seen under the same or equal angles, appear equal; and vice versa.

MAGNOLIA, a genus of the polygynia order, belonging to the polyandria class of plants; and in the natural method ranking under the 52nd order, coadnatæ. The calyx is triphyllous; there are nine petals; the capsules bivalved and imbricated; the seeds pendulous, and in the form of a berry. There are seven species: the principal are,

1. The glauca, or small magnolia, a native of Virginia, Carolina, and other parts of North America. In moist places it rises from seven or eight to fifteen or sixteen feet high, with a slender stem. The wood is white and spongy, the flowers are produced at the extremities of the branches, are white, composed of six concave petals, and have an agreeable scent. 2. The grandiflora, or great magnola, is a native of Florida and South Carolina. It rises, to the height of eighty feet or more, with a straight trunk upwards of two feet diameter, having a regular head. The leaves resemble those of the laurel, but are larger, and continue green throughout the year. The flowers are produced at the ends of the branches, and are of a purplish-white colour. 3. The tripetala, or umbrella tree, is a native of Carolina; it rises, with a slender trunk, to the height of sixteen ort wenty feet; the wood is soft and spongy; the leaves remarkably large, and pro-

duced in horizontal circles, somewhat resembling an umbrella, whence the inhabitants of those countries have given it this name. The flowers are composed of ten or eleven white petals, that hang down without any order. The leaves drop off at the beginning of winter. 4. The acuminata, with oval, spear-shaped, pointed leaves, is a native of the inland parts of North America. The leaves are near eight inches long, and five broad, ending in a point. The flowers come out early in the spring, and are composed of twelve white petals; the wood is of a fine grain. and an orange colour.

MAHERNIA, a genus of the class and order pentandria pentagynia. The cal. is 5-toothed: petals 5; nec. 5 obcordate, placed under the filaments; caps. 5-celled. There are three species, shrubs of the Cape. The incisa is a beautiful little shrub for the greenhouse.

MAIL. or *coat of* MAIL, a piece of defensive armour for the body, made of small iron rings, interwoven in the manner of a net.

MAIM, MAIHEM, or MAYHEM, in law. It is enacted, by the statute of 22 and 23 Car. II. that if any person from malice aforethought, shall disable any limb or member of any of the king's subjects with an intent to disfigure them, the offender, with his aides and abettors, shall be guilty of felony without benefit of clergy; though no such attainder shall corrupt the blood, or occasion forfeiture of lands, &c.

If a man attack another with an intent to murder him, and he does not murder the man, but only maim him, the offence is nevertheless within the statute 22 and 23 Car. II. c. I, usually called the Coventry act. 1 Haw. 112.

MAINPRISE, the taking or receiving a man into friendly custody, that otherwise is or might be committed to prison, upon security given for his forthcoming at a day assigned. See BAIL BOND.

MAINTENANCE, is the unlawful taking in hand, or upholding; of a cause or person: this offence bears a near resemblance to barratry, being a person's intermeddling in the suit of another, by maintaining or assisting him with money, or otherwise, to prosecute or defend it. A man may maintain the suit of his near kinsman, servant, or poor neighbour, out of charity or compassion, without being guilty of maintenance. By the common law, persons guilty of maintenance may be prosecuted by indictment, and be fined and imprisoned, or be compelled to make satisfaction by action, &c.; and a court of record may commit a man for an act of maintenance done in the face of the court. 1 Inst. 368.

MAJOR, in logic, the first proposition of a syllogism.

MAJOR and MINOR, in music, signify imperfect concords, which differ from each other by a semitone minor.

MALACHODENDRUM, a genus of the class and order monadelphia polyandria. The cal. is simple; germ. pear-shaped, pentagonal; styles, 5; caps. 5, one-seeded: one species, of no note.

MALACHOA, a genus of the class and order monadelphia polyandria. The cal. is common, 3-leaved, many-flowered, longer; arils 5, 1-seeded. There are five species, herbs of the West Indies.

MALACHITE, green carbonat of copper. This ore is often amorphous, but often crystallized in long slender needles.

Colour green. Brittle. Specific gravity 3·571 to 3.653. Effervesces with nitric acid, and gives a blue colour to ammonia. Before the blowpipe it decripitates and blackens, but does not melt. Tinges borax yellowish green. Tinges flame green.

Variety 1. Fibrous malachite.—Texture fibrous. Opaque when amorphous; when crystallized it is partly transparent is 2. Colour generally grass-green.

Variety 2. Compact malachite.—Texture compact. Opaque. Colour varies from the dark emerald-green to blackish green.

A specimen of malachite from Siberia, analysed by Klaproth, contained

58.0	copper
18.0	carbonic acid
12.5	oxygen
11.5	water
100.	

This species is sometimes mixed with clay, chalk, and gypsum, in various proportions; it it then known by the name of common mountain-green. Its colour is verdigris-green. Brittle. Texture earthy. Effervesces feebly with acids. Before the blowpipe it exhibits the same phenomena as malachite.

A comparison of the analysis of Klaproth with that of Pelletier seems to prove that malachite contains copper oxidized to a greater degree than blue copper ore.

MALACOLITE. This mineral was first observed in Sweden in the silver-mine of Sahla in Westermania; afterwards in Norway. Colour green. Found massive and crystallized in six-sided prisms, having two opposite edges truncated. Waxy. Texture lamellated. Feel soft. Specific gravity 3.2307. Melts before the blowpipe into a porous glass. According to the analysis of Vauquelin, it is composed of

53	silica
20	lime
19	magnesia
3	alumina
4	oxide of iron and manganese
99	

MALATS, in chemistry. This genus of salts is almost unknown, owing chiefly to the difficulty of procuring pure malic acid. The followiug are the only facts hitherto ascertained.

Malat of potass.
Malat of soda.
Malat of Ammonia.

These salts were formed by Scheele. They are deliquescent and very soluble.

Malat of Barytes. When malic acid is dropt into barytes water, a white powder precipitates, which is malat of barytes. According to Scheele, the properties of this salt resemble those of malat of lime.

Malat of strontian. Malic acid occasions no precipitate in strontian water. Hence it follows, that malat of strontian is more soluble than malat of barytes.

When malic acid is neutralized with lime, it forms a salt scarcely soluble in water, which may be obtained in crystals, by allowing the supermalat of lime to evaporate spontaneously. Crystals of natural malat are formed in the solution. But this acid has a strong tendency to

combine in excess with lime, and to form a supermalat of lime. This salt is formed when carbonat of lime is thrown into malic acid, or into any liquid containing it. This supersalt exists in various vegetables, especially the supervivum tectorum, and some of the sedums.

Supermalat of lime has an acid taste. It yields a precipitate with alkalies, sulphuric acid, and oxalic acid. Lime-water saturates the excess of acid, and throws down a precipitate of malt of lime. When the supermalet of lime is evaporated to dryness, it assumes exactly the appearance of gum arabic; and if it has been spread thin upon the nail or wood, it forms a varnish. It is not so soluble in water as gum arabic, and the taste readily distinguishes the two. Supermalet of lime is insoluble in alcohol.

Malet of magnesia, this salt is very soluble in water, and when exposed to the air deliquesces.

Malat of alumina. This salt is almost insoluble in water. Of course it precipitates when malic acid is dropt into a solution containing alumina. Mr. Chenevix has proposed this acid to separate alumina from magnesia; which earths, as it is well known, have a strong affinity for each other.

MALAXIS, a genus of the class and order gynandria diandria. The nec. is one-leaved, concave, coruate; acumina, pale, bifid in front. There are two species, bulbs of Jamaica.

MALIC *acid*, obtained from the juice of apples; it is also extracted from the juice of commom house-leek, where it exists combined with lime. The process is as follows: To the juice of the house-leek add acetat of lead as long as any precipitate takes place. Wash the precipitate, and decompose it by means of diluted sulphuric acid in the manner directed by Scheele.

Malic acid may be formed also by the action of nitric acid of sugar. If nitric acid is distilled with an equal quantity of sugar, till the mixture assumes a brown colour (which is a sign that all the nitric acid has been abstracted from it), this substance will be found of an acid taste; and after all the oxalic acid which may have been formed is separated by lime-water, there remains another acid, which may be obtained by the following process: saturate it with lime, and filtre the solution: then pour upon it a quantity of alcohol, and a coagulation takes place. This coagulation is the acid combined with lime. Separate it by filtration, and edulcorate it with fresh alcohol; then dissolve it in distilled water, and pour in acetat of lead till no more precipitation ensues. The precipitate is the acid combined with lead, from which it may be separated by diluted sulphuric acid.

Malic acid, thus obtained, is a liquid of a reddish-brown colour and a very acid taste. When evaporated it becomes thick and viscid like a mucilage or syrup, but it does not crystallize. When exposed to a dry atmosphere in thin layers, it dries altogether, and assumes the appearance of varnish. When heated in the open fire it becomes black, swells up, exhales an acrid fume, and leaves behind it a very voluminous coal. When distilled, the products are an acid water; a little carbureted hydrogen gas, and a large proportion of carbonic acid. It is very soluble in water. It gradually decomposes spontaneously, by undergoing a kind of fermentation in the vessels in which it is kept. Sulphuric acid chars it, and nitric acid converts it into ozalic acid. Hence it is evident that it is composed of oxygen, hydrogen, and carbon, though the proportion of these substances have not been ascertained.

Malic acid combines with alkalies, earths, and metallic oxides, and forms salts known by the name of Malats, which see.

Its affinities have not yet been ascertained.

This acid bears a strong resemblance to the nitric, but differs from it in the following particulars: 1. The citric acid shoots into fine crystals, but this acid does not crystallize. 2. The salt formed from the citric acid with lime is almost insoluble in boiling water; whereas, the salt made with malic acid and the same basis is readily soluble by boiling water. 3. Malic acid precipitates mercury, lead, and silver, from the nitrous acid, and also the solution of gold when diluted with water; whereas citric acid does not alter any of these solutions. 4. Malic acid seems to have a less affinity than citric acid for lime; for when a solution of lime in the former is boiled a minute, with a salt formed from volatile alkali and citric acid, a decomposition takes place, and the latter acid combines with the lime, and is precipitated.

MALLEABLE, a property of metals, whereby they are capable of being extended under the hammer.

MALOPE, a genus of the class and order monadelphia polyandria. The calyx is double, outer three-leaved; arils glomerate, one-seeded. There are two species, herbs of Tuscany, &c.

MALPIGHIA, *Barbadoes cherry*, a genus of the trigynia order, in the decandria class of plants, and in the natural method ranking under the 23d order, trihilatæ. The calyx is pentaphylloas, with melliferous pores on the outside at the base. There are five petals, roundish and unguiculated; the berry unilocular and trispermous. There are 18 species, all of them shrubby evergreens of the warm parts of America, rising with brancby stems from 8 or 10 to 15 or 20 feet high, ornamented with oval and lanceolate entire leaves, and large pentapetalous flowers, succeeded by red, cherry-shaped, eatable berries, of an acid and palatable flavour; and which in the West Indies, where they grow naturally, are used instead of cherries. Three of the species are reared in English gardens, and make a fine variety in the stove. They retain their leaves all the year round; and begin to flower about the end of autumn, continuing in constant succession till the spring: after which they frequently produce and ripen their fruit, which commonly equals the size of a small cherry. The flowers are of a pale-red or purple colour.

MALT, is barley prepared, to fit it for making a potable liquor called beer, or ale, by stopping it short at the beginning of vegetation.

In making malt from barley, the usual method is to steep the grain in a sufficient quantity of water, for two or three days, till it swells, becomes plump, somewhat tender, and tinges the water of a bright-brown, or reddish colour. Then this water being drained away, the barley is removed from the steeping cistern to the floor, where it is thrown into what is called the wet couch; that is, an even heap, rising to the height of about two feet. In this wet couch the capital part of the operation is performed; for here the barley spontaneously heats, and begins to grow, shooting out first the radicle; and if suf-

fered to continue, then the plume, spire, or blade. But the process is to be stopped short at the eruption of the radicle, otherwise the malt would be spoiled. In order to stop it, they spread the wet couch thin over a large floor, and keep turning it once in four or five hours, for the space of two days, laying it somewhat thicker each time. After this, it is again thrown into a large heap, and there suffered to grow sensibly hot to the hand, as it usually will in 20 or 30 hours time; then being spread again, and cooled, it is thrown upon the kiln, to be dried crisp without scorching.

MALTA, KNIGHTS OF, otherwise called *hospitalers of St. John of Jerusalem*, a religious military order, whose residence is in the island of Malta. The order consists of three estates, the knights, chaplains, and servants at arms: there are also priests who officiate in the churches, friar-servants who assist at the offices, and donnes or demicrosses; but these are not reckoned constituent parts of the body: the government of the order is mixt, being partly monarchical, and partly aristocratical: the grand master is sovereign. The knights formerly consisted of eight different languages, but now only seven, the English having withdrawn themselves. None are admitted into this order but such as are of noble birth: the knights are of two sorts, those who have a right to be candidates for the dignity of grand-master, called grand-crosses, and those who are only knights assistants: they never marry. The knights are received into this order, either by undergoing the trials prescribed by statutes, or by dispensation.

MALTHA, in antiquity, a kind of cement of which there were two sorts, native and factitious; one of the latter sort, much in use, consisted of pitch, wax, plaister, and grease. Another kind used by the Romans in their aqueducts, was made of lime slacked in wine, incorporated with melted pitch, and fresh figs. Natural maltha is a kind of bitumen, with which the Asiatics plaister their walls; and which being once set on fire, water makes it burn more fiercely. See BITUMEN.

MALVA, the *mallow*, a genus of the polyandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is double; the exterior one triphyllous; the arilli numerous and monospermous. There are 34 species, consisting of herbaceous perennials, biennials, and annuals, for medical, economical, and ornamental uses.

The leaves of the common mallow are reckoned the first of the four emollient herbs: they were formerly in some esteem as food; at present decoctions of them are sometimes employed in dysenteries, heat, and sharpness of urine, and in general for obtunding acrimonious humours: their principal use is in emollient glysters, cataplasms, and fomentations. The leaves enter the officinal decoction for glysters, and a conserve is prepared from the flowers. Several pieces of malva, macerated like hemp, afford a thread superior to hemp for spinning, and which is said to make more beautiful cloths and stuffs than even flax. These species are the crispa, Peruviana, and Maurisiana. From the former, which affords stronger and longer fibres, cords and twine have also been made. From the malvæ likewise a new sort of paper has been fabricated by M. de l'Isle.

MAMMÆ, in anatomy, the breasts of a female.

MAMMALIA, in natural history, the first class of animals in the Linnæan system, divided into seven orders. See ZOOLOGY.

MAMMEA, *mammee-tree*, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is tetrapetalous; the calyx diphyllous; the berry very large and tetraspermous. There is one species, a large evergreen tree of the hot parts of America and Asia, adorned with large, oval, oblong, stiff leaves, and large quadripetalous flowers, succeeded by large, round, eatable fruit, of a most exquisitely rich flavour. They are propagated by seed, which in cold countries is to be sowed in small pots of light earth, and kept in the stove.

MAMMILLARY. See ANATOMY.

MANATI, in zoology, See TRICHECUS.

MANCA, was a square piece of gold coin, commonly valued at 30 pence; and mancusa was as much as a mark of silver, having its name from manu cusa, being coined with the hand (Leg. Canut.). But the manca and mancusa were not always of that value: for sometimes the former was valued at six shillings, and the latter, as used by the English Saxons, was equal in value to our half-crown.

MANDAMUS, is a writ issuing in the king's bench, and directed to any person, corporation, or inferior court of judicature, commanding to some particular thing therein specified, as appertaining to their office and duty.

A writ of mandamus is a high prerogative writ, of a most extensive remedial nature, and may be issued in some cases where the injured party has also another more tedious method of redress, as in the case of admission or restitution to an office; but it issues in all cases where the party has a right to have any thing done, and has no other specific means of compelling its performance. 3 Black. 100.

And this general jurisdiction and superintendance of the king's bench over all inferior courts to restrain them within their bounds, and to compel them to execute their jurisdiction, whether such jurisdiction arises from a modern charter, subsists by custom, or is created by act of parliament, yet being in subsidium justitiæ, has of late been exercised in a variety of instances.

Mandamus was also a writ that lay after the year and a day (where, in the mean time, the writ called diem clausit extremum had not been sent out) to the escheator, commanding him to inquire of what lands holden by knight-service the tenant died seized, &c. F. N. B. 561.

Mandamus was also a writ to charge the sheriff to take into the king's hands all the lands and tenements of the king's widow, who, against her oath formerly given, marries without the king's consent. Reg. 295.

MANETTIA, a genus of the class and order tetrandria monogynia. The calyx is eight leaved; corolla four-cleft; capsule inferior, two-valved, one-celled; seeds imbricate, unilocular. There are three species, shrubs of of the West Indies.

MANGANESE. I. The dark-grey or brown mineral called manganese has been long known and used in the manufacture of glass. A mine of it was discovered in England by Mr. Boyle. A few experiments were made upon this mineral by Glauber in 1656, and by

Waitz in 1795; but chemists in general seem to have paid but very little attention to it. The greater number of mineralogists, though much puzzled what to make of it, agreed in placing it among iron ores: but Pott, who published the first chemical examination of this mineral in 1740, having ascertained that it often contains scarcely any iron, Cronstedt, in his System of Mineralogy, which appeared in 1758, assigned it a place of its own, on the supposition that it consisted chiefly of a peculiar earth. Rinman examined it anew in 1765; and in the year 1770 Kaim published at Vienna a set of experiments, in order to prove that a peculiar metal might be extracted from it. The same idea had struck Bergman about the same time, and induced him to request of Scheele, in 1771, to undertake an examination of manganese. Scheele's dissertation on it, which appeared in 1774, is a masterpiece of analysis, and contains some of the most important discoveries of modern chemistry. Bergman himself published a dissertation on it the same year; in which he demonstrates that the mineral, then called manganese, is a metallic oxide. He accordingly made several attempts to reduce it, but without success; the whole mass either assuming the form of scoriæ, or yielding only small separate globules attracted by the magnet. This difficulty of fusion led him to suspect that the metal he was in quest of bore a strong analogy to platinum. In the mean time Dr. Gahn, who was making experiments on the same mineral, actually succeeded in reducing it by the following process: he lined a crucible with charcoal-powder moistened with water, put into it some of the mineral formed into a ball by means of oil, then filled up the crucible with charcoal-powder, luted another crucible over it, and exposed the whole for about an hour to a very intense heat. At the bottom of the crucible was found a metallic button, or rather a number of small metallic globules, equal in weight to one-third of the mineral employed. It is easy to see by what means this reduction was accomplished. The charcoal attracted the oxygen from the oxide, and the metal remained behind. The metal obtained, which is called manganese, was farther examined by Ilseman in 1782, Hielm in 1785, and Bindheim in 1789.

Manganese, when pure, is of a greyish-white colour, and has a good deal of brilliancy. Its texture is granular. It has neither taste nor smell. Its hardness is equal to that of iron. Its specific gravity is 7.000. It is very brittle; of course it can neither be hammered, nor drawn out into wire. Its tenacity is unknown. It requires, according to Morveau, the temperature of 160° Wedgewood to melt it; so that plantinum excepted, it is the most infusible of all the metals. When reduced to powder it is attracted by the magnet, owing probably to a small portion of iron from which it can with difficulty be parted.

II. Manganese, when exposed to the air, attracts oxygen more rapidly than any other body, phosphorus excepted. It loses its lustre almost instantly, becomes grey, violet, brown, and at last black. These changes take place still more rapidly if the metal is heated in an open vessel.

This metal seems capable of combining with three different proportions of oxygen, and of forming three different oxides, the white, the red, and the black.

The protoxide or white oxide may be obtained by dissolving the black oxide of manganese in nitric acid by adding a little sugar. The sugar attracts oxygen from the black oxide, and converts it into the white, which is dissolved by the acid. Into the solution pour a quantity of potass; the protoxide precipitates in the form of a white powder. It is composed, according to Bergman, of 80 parts of manganese and 20 of oxygen. When exposed to the air it soon attracts oxygen, and is converted into the black oxide.

The deutoxide or red oxide may be obtained by dissolving the black oxide in sulphuric acid, without the addition of any combustible substance. When black oxide of maganese, made into a paste with sulphuric acid, is heated in a retort, a great quantity of oxygen gas comes over, while the oxide, thus deprived of part of its oxygen, dissolves in the acid. Distil to dryness, and pour water upon the residuum, and pass it through a filtre. A red-coloured solution is obtained, consisting of the sulphat of manganese dissolved in water. On the addition of an alkali a red substance precipitates, which is the red oxide of manganese. According to Bergman it is composed of 74 parts of manganese and 26 of oxygen. This oxide likewise attracts oxygen when exposed to the atmosphere, and is converted into the black oxide.

The peroxide of black oxide of manganese exists abundantly in nature; indeed it is almost always in this state that manganese is found. It was to the black oxide that the appellation manganese itself was originally applied. It may be formed very soon by exposing the metal to the air. This oxide, according to Fourcroy, is composed of 60 parts of manganese and 40 of oxygen. When heated to redness in an earthen retort it gives out abundance of oxygen gas, which may be collected in proper vessels. By this operation it is reduced nearly to the state of red oxide. If it is exposed to the air, and moistened occasionally, it absorbs a new dose of oxygen; and thus the same process may again be repeated. No oxygen gas can be obtained from the white oxide: a proof that its oxygen is retained by a stronger affinity than the additional dose of oxygen which constitutes the black oxide. Seguin has observed, that in some cases the black oxide of manganese emits, before it becomes red, a quantity of azotic gas. When long exposed to a strong heat it assumes a green colour. In that state it is whitened by sulphuric acid, but not dissolved. A very violent heat fuses this oxide, and converts it into a green-coloured glass.

III. Manganese does not combine with hydrogen. When dissolved in sulphuric acid a black spongy mass of carburet of iron is left behind. Hence it has been supposed capable of combining with carbon; but it is more probable that the carbon is combined with the iron, which is almost always present in manganese. It seems pretty clear, however, that carburet of iron is capable of combining with this metal, and that it always forms a part of steel.

Bergman did not succeed in his attempt to combine manganese with sulphur; but he formed a sulphureted oxide of manganese, by combining eight parts of the black oxide with three parts of sulphur. It is of a green colour, and gives out sulphureted hydrogen gas when acted on by acids. It cannot be doubted, however, that

the sulphur is capable of combining with manganese; for Proust has found native sulphuret of manganese in that ore of tellurium which is known by the name of gold ore of Nagyag.

Phosphorus may be combined with manganese by melting together equal parts of the metal and of phosphoric glass; or by dropping phosphorus upon red-hot manganese. The phosphuret of manganese is of a white colour, brittle, granulated, disposed to crystalize, not altered by exposure to the air, and more fusible than manganese. When heated the phosphorus burns, and the metal is oxidized.

IV. Manganese does not combine with either of the simple combustibles.

V. Manganese combines with many of the metals, and forms with them alloys which have been but very imperfectly examined.

It unites readily with copper. The compound, according ty Bergman, is very malleable, its colour is red, and it sometimes becomes green by age. Gmelin made a number of experiments to see whether this alloy could be formed by fusing the black oxide of manganese along with copper. He partly succeeded, and proposed to substitute this alloy instead of the alloy of copper and arsenic, which is used in the arts.

It combines readily with iron; indeed it has scarcely been found quite free from some mixture of that metal. Manganese gives iron a white colour, and renders it brittle. It combines also with tin, but scarcely with zinc.

It does not combine with mercury nor with bismuth. Gmelin found that manganese cannot be alloyed with bismuth without great difficulty; and that it unites to antimony very imperfectly. Chemists have not attempted to combine it with gold, plantinum, silver, nickel, nor cobalt.

VI. The affinities of manganese, and of its white and red oxides, are, according to Bergman, as follows:

Manganese.	*Oxide of manganese.*
Copper,	Oxalic acid,
Iron,	Citric,
Gold,	Phosphoric,
Silver,	Tartaric,
Tin,	Fluoric,
	Muriatic,
	Sulphuric,
	Nitric,
	Saclactic,
	Succinic,
	Tartaric,
	Lactic,
	Acetic,
	Prussic,
	Carbonic.

MANGIFERA, the *mango-tree*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous; the plum kidney-shaped. There are three species, the principal of which is a native of many parts of the East Indies, whence it has been transplanted to Brazil, and other warm parts of America. It grows to a large size; the wood is brittle; the bark rough when old; the leaves are seven or eight inches long, and more than two inches broad. The flowers are produced in loose panicles at the ends of the branches, and are succeeded by large oblong kidney-shaped plums. This fruit, when fully ripe, is greatly esteemed in the countries where it grows; but in Europe they have only the unripe fruit brought over in pickle. All attempts to propagate the plant have hitherto proved ineffectual; and Mr. Millar is of opinion that the stones will not vegetate unless they are planted soon after they are ripe.

MANIA. See MEDICINE.

MANICHEES, in church history, a sect of christian heretics in the third century, the followers of Manes, who made his appearance in the reign of the emperor Probus; pretending to be the Comforter, whom our saviour promised to send into the world. He taught that there are two principles, or gods, coeternal and independant on each other; the one the author of all evil, and the other of all good; a doctrine which he borrowed from the Persian magi. He held that our souls were made by the good principle, and our bodies by the evil one: and that the souls of his followers passed through the elements to the moon, and from thence to the sun, where being purified, they then went to God, and became united with his essence; but as for the souls of other men, they either went to hell, or were united to other bodies.

MANILLE, in commerce, a large brass ring, in the form of a bracelet, either plain or engraven, flat or round. Manilles are the principal commodities which the Europeans carry to the coast of Africa, and exchange with the natives for slaves. These people wear them as ornaments on the small of the leg, and on the thick part of the arm above the elbow. The great men wear the manilles of gold and silver, but these are made in the country by the natives themselves.

MANIPULUS, in Roman antiquity, a body of infantry, consisting of 200 men, and constituting the third part of a cohort. See COHORT.

MANIS, a genus of quadrupeds of the order of bruta. The generic character is, teeth none; tongue cylindric and extensile; mouth narrowed into a snout; body covered with scales. The genus manis presents an appearance not less extraordinary than that of dasypus or armadillo; being covered on every part, except on the belly, with extremely strong and large horney scales, constituting a suit of armour still more powerful than in the following genus, and capable of defending the animals, when rolled up from the assaults of the most ferocious enemies. This external covering, together with the uncommon length of the body and tail, gives an aspect so much resembling that of a lizard, that these creatures are commonly known by the title of scaly lizards: they may be allowed, however, in a general view of the animal kingdom, to form a kind of shade or link of approximation between the proper viviparous quadrupeds and the lizards.

They are animals of a harmless nature, and feed in the same manner as the ant-eaters, by thrusting out their very long tongue into the nests of ants and other insects, and swallowing their prey by suddenly retracting it, having no teeth, and differing from the ant-eaters in scarcely any other circumstance than that of their

scaly integment. They are found in India and the Indian islands.

1. Manis tetradactyla, long-tailed manis. This animal, known in India by the name of the phatagen; is of a very long and slender form: the head is small; the snout narrow; the whole body, except beneath, covered with broad, but sharp-pointed, scales, which are striated through their whole length: the tail is more than twice the length of the body, and tapers gradually to the tip. The legs are very short, scaled like the body, and on each of the feet are four claws, of which those on the fore feet are stronger than those of the hind. The colour of the whole animal is an uniform deep-brown, with a cast of yellowish, and with a glossy or polished surface. The manis tetradactyla grows to the length of five feet, measuring from the tip of the nose to the extremity of the tail.

2. Manis pentadactyla, short-tailed manis, differs from the former, in being of a much thicker and shorter form; the tail, in particular, differs greatly in proportion from that of the preceeding, being not so long as the body, very thick at the base, and thence gradually tapering, but terminating very obtusely. The head is small as in the former; the ears small and rounded; the feet furnished with five toes each, of which those on the fore feet are extremely strong, except the exterior one, which is much smaller than the rest. The whole animal is covered with most extremely thick, strong, and large scales, which in the full-grown specimens are perfectly smooth, but in those which are smaller are slightly striated about half way from the base. Sometimes a few bristles appear between the scales, but in others this is not observable. The scales differ in shape from those of the preceeding, being much wider and larger in proportion to the body and tail. The colour of the whole animal is a very pale yellow brown, and the surface is glossy, as in the former species. In India it is called the pongoelling. In the neighbourhood of Bengal it is named vajracite, or the thunderbolt reptile, from the excessive hardness of the scales, which are said to be capable even of striking fire like a flint. It is said to walk slowly; but, when pursued, rolls itself up, and is then so securely armed, that even a leopard attacks it in vain. It is also said sometimes to destroy the elephant, by twisting itself round the trunk, and thus compressing that tender and sensible organ with its hard scales. We are told in the Asiatic Researches that the Malabar name of this animal is alungu; and that the natives of Bahar call it bajar-cit, or the stone vermin; and in the stomach of the one examined and described in the above work was found about a teacupful of small stones, which it is supposed to have swallowed for the purpose of facilitating digestion. It was only 34 inches long from the nose to the end of the tail; and a young one was found in it.

Specimens of the manis pentadactyla have sometimes been seen of the length of six feet from the nose to the tip of the tail. See Pl. LXXXIV. Nat. Hist. fig. 258.

MANNA, in natural history. This substance exudes from the fraxinus ornus, in the months of June and July, from the stem and branches. It is at first liquid, but gradually becomes solid. It is collected in Sicily and the southern parts of Italy, It is in form of oblong globules of a whitish-yellow colour, and somewhat transparent. It is very light. Its taste is sweet, and it leaves a nauseous bitter impression in the mouth. Its properties have not been examined by chemists. It acts as a mild cathartic. See Materia Medica.

MANOMETER, or Manoscope, an instrument to show or measure the alterations in the rarity or density of the air. The manometer differs from the barometer in this, that the latter only serves to measure the weight of the atmosphere; or of the column of air over it, but the former of the density of air in which it is found; which density depends not only on the weight of the atmosphere, but also on the action of heat and cold, &c. Authors, however, generally confounded the two together: and Mr. Boyle himself gives us a very good manometer of his contrivance, under the name of statical barometer, consisting of a bubble of thin glass, about the size of an orange, which, being counterpoised when the air was in a mean state of density, by means of a nice pair of scales. sunk when the atmosphere became lighter, and rose as it grew heavier. See Meterology.

MANOR, was a district of ground held by lords or great personages, who kept in their own hands so much land as was necessary for the use of their families, which were called terræ dominicales, or demesne lands, being occupied by the lord, or dominus manerii, and his servants. The other lands they distributed among their tenants, which the tenants held under divers services. The residue of the manor being uncultivated was termed the lord's waste, and served for common of pasture to the lord and his tenants. All manors existing at this day must have existed as early as king Edward the First. 2 Black. 90. See Court Baron.

MANSLAUGHTER, is unlawfully killing a man without any malice prepense, or forethought. The English law very humbly makes a distinction between a hasty and deliberate act: as when two persons on a sudden quarrel, fight, and one is killed; yet as it is done in a sudden heat of passion, and not with any premeditated malice, it is manslaughter, and not murder. See Murder.

This crime may be either voluntary, as on a sudden loss of temper; as if a man is greatly provoked, and kills the aggressor, it is manslaughter; but if it appears that there was a sufficient cooling time for the heat of anger to subside, this shows deliberate revenge, and amounts to murder. Or it may be involuntarily; but in the commission of some unlawful act; in which latter respect it differs from homicide per infortunium: as if one shoots off a gun in a highway, and where people often meet, and kills a man: or if he is shooting at game, and is not qualified or licensed, and kills another, it is manslaughter. And, in general, when an involuntary killing happens, in consequence of an unlawful act, it will be murder or manslaughter, according to the act which occasioned it.

It is evident from the nature of this crime that there can be no accessaries, because it must be done without premeditation; but when two men once fell out, and immediately fought, and the sword of one was broken, and his friend lent him another, with which he killed his antagonist, it was made manslaughter in both. Again: there were two men in a room quarreling; a brother of one of them standing at the door, who cold not get in, cried out to his brother to make him sure, and the bro-

ther killed his antagonist: it was likewise manslaughter in both.

But if any person shall stab another, not having his weapon drawn, or not strucken first, so that he dies within six months, although it be not of malice aforethought, it is felony without benefit of clergy.

This crime, though felony, is within benefit of clergy; and the offender shall be burnt in the hand, and forfeit all his goods and chattels; but by stat. 19 Geo. III. c. 74, it is made lawful for the court to commute this punishment for a moderate fine and imprisonment.

MANTELETS, in the art of war, a kind of moveable parapets, made of planks about three inches thick, nailed one over another, to the height of almost six feet, generally cased with tin, and set upon little wheels, so that in a siege they may be driven before the pioneers, and serve as blinds to shelter them from the enemy's small shot.

MANTIS, a genus of insects of the order hemiptera. The generic character is, head unsteady, armed with jaws, and furnished with palpi or feelers; antennæ setaceous; thorax linear; wings four, membranaceous, convoluted, the lower pair pleated; fore legs, in most species, compressed, serrated beneath, and armed with a single claw and a setaceous, lateral, jointed foot; hind legs smooth, formed for walking. This is one of the most singular genera in the whole class of insects; and imagination itself can hardly conceive shapes more strange than those exhibited by some particular species. See Plate LXXXIV. Nat. Hist. fig. 259.

The chief European kind is the mantis oratoria of Linnæus, or camel cricket, as it is often called. This insect, which is a stranger to the British isles, is found in most of the warmer parts of Europe, and is entirely of a beautiful green colour. It is nearly three inches in length, of a slender shape, and in its general sitting posture is observed to hold up the two fore legs, slightly bent, as if in an attitude of prayer: for this reason the superstition of the vulgar has conferred upon it the reputation of a sacred animal; and a popular notion has often prevailed, that a child or traveller having lost his way would be safely directed by observing the quarter to which the animal pointed when taken into the hand. In its real disposition it is very far from sanctity, preying with great rapacity on any of the smaller insects which fall in its way, and for which it lies in wait with anxious assiduity in the posture at first mentioned, seizing them with a sudden spring when within its reach, and devouring them. It is also of a very pugnaceous nature; and when kept with others of its own species in a state of captivity, will attack its neighbour with the utmost violence, till one or the other is destroyed in the contest.

Among the Chinese this quarrelsome property in the genus mantis is turned into a similar entertainment with that afforded by fighting cocks and quails.

The mantis precaria is a native of many parts of Africa, and is the supposed idol of the Hottentots, which those superstitious people are reported to hold in the highest veneration, the person on whom the adored insects happens to light being considered as favoured by the distinction of a celestial visitant, and regarded ever after in the light of a saint. This species is of the same general size and shape with the M. oratoria, and is of a beautiful green colour, with the thorax ciliated or spined on each side, and the upper wings each marked in the middle by a semitransparent spot.

Of all the mantes perhaps the most singular in its appearance is the mantes gongylodes of Linnæus, which, from its thin limbs, and the grotesque form of its body, especially in its dried state, seems to resemble the conjunction of several fragments of withered stalks. There are 14 species of this genus.

MANTLE, or MANTLING, in heraldry, that appearance of folding of cloth, flourishing, or drapery, that is in any achievement drawn about the coat of arms.

MANURE, any thing used for fattening and improving land. See HUSBANDRY.

MAP, a plane figure, representing the surface of the earth, or a part thereof.

In maps these three things are essentially requisite. 1. That all places have the same situation and distance from the great circles therein, as on the globe, to show their parallels, longitudes, zones, climates, and other celestial appearances. 2. That their magnitudes be proportionable to their real magnitudes on the globe. 3. That all places have the same situation, bearing, and distance, as on the earth itself.

The true chart performs the first and last of these very exactly, but fails extravagantly in the second; and indeed no kind of projection yet found can exhibit more than two of them at once, by reason of the great difference between a plane and convex superficies.

Maps are not always to be used as they lie before us, for sometimes any part is uppermost; but, generally, the top is the north part, the bottom the south, the right hand the east, and the left hand the west, and marked with these words, or Latin ones of the same import. There is also inscribed a compass, pointing to all the quarters of the world, the north one being marked with a flower deluce.

The degrees of longitude are always numbered at top and bottom, and the degrees of latitude on the east and west sides. In all right-lined and general circular maps, except those of Wright's projection, the degrees of latitude on the sides are of an equal breadth; and in all circular and right-lined maps, except the said Wright's, and the plane charts, the degrees of longitude are unequal.

In general maps the circles corresponding to those in the heavens are inscribed, viz. the equator is expressed by a straight east and west line; and the first meridian, the polar circles, the tropics, and the other meridians and parallels, which are drawn at every five or ten degrees, intersect each other at right angles.

The most natural method of representing a sphere upon a plane seems to be, to divide it into two equal parts, and inscribe each of them in a circle: but as the equator, and the polar axis, which intersects that circle at right angles, and makes one of the meridians, must be supposed equal in length to the half of the periphery (which is not quite two-thirds), it follows of course, that the countries delineated upon, or near, these lines, must be reduced to somewhat less than two-thirds of the size of the countries of equal extent, which lie at the extremity of the circle; and that the lines drawn to measure the latitude, which are parallel to each other, or nearly so, must, in order to preserve as nearly as possible their pro-

portional angles at the points of intersection with the meridians, from segments of circles, of which no two are parallel or concentric.

There may be as many different projections as there are points of view in which a globe can be seen, but geographers have generally chosen those which represent the poles at the top and bottom of the map; these, from the delineation of the lines of latitude and longitude, are called the stereographic, orthographic, and globular projections.

We do not propose to detain the reader with a description of all the projections, some of which are so erroneous (for the purpose of constructing of maps) as to deserve being consigned entirely to oblivion. But as the projection of maps is a pleasing and instructive exercise, and indeed indespensably necessary to the right understanding of geography to students, we shall describe the manner of constructing the map of the world. With regard to the stereographic projection it may be observed, that among the various positions assignable to the eye there are chiefly two that have been adopted, wherein the eye is placed either in the points D, fig. 1, or removed to an infinite distance; and hence this projection is liable to the great error of distorting the form of the countries represented upon it much more than is necessary. The only advantage is, that the lines of latitude and longitude intersect each other at right angles.

This being observed by that excellent astronomer, M. de la Hire, he invented a remedy for the inconvenience, by assigning to the eye a position at the point O, fig. 1, the distance of which from the globe at D is equal to the right sine of 45 degrees; and hence the right line GO, which bisects the quadrant BC, also bisects the radius EC, and produces the similar triangles OFG, and OEI; and thus the other parts of the quadrant BC, and in like manner of the whole semicircle ABC, are represented in the projection nearly proportionable to each other, and to sense perfectly so. The delineation of the earth and sea upon this projection (which, as coming the nearest to a true representation of the globe, is called the globular projection), is equal to the stereographic in point of facility, and vastly superior to it in point of truth.

Geometrical construction of the globular projection.—From the centre C, fig. 2, with any radius, as CB, describe a circle; draw the diameters AB, and 90, 90, at perfect right angles to one another, and divide them into nine equal parts; likewise divide each quadrant into nine equal parts, each of which contains ten degrees; if the scale admits of it, every one of these divisions may be subdivided into degrees: next, to draw the meridians, suppose the meridian 80° W. of Greenwich, we have given the two poles 90, 90, and the point 80 in the equator, or diameter AB; describe a circle to pass through the three given points as follows: with the radius 90 set one foot of the compasses on the point 90, and describe the semicircles XX and ZZ, then remove the compasses to the point 80 on the equator, and describe the arcs 1, 1, and 2, 2; where they intersect the semicircle make the point, as at 1 and 2, and draw lines from 2 through the point 1 till they intersect the diameter BA continued in E: then will E be the centre from whence the meridian 90, 80, 90, must be drawn, and will express the meridian of 80° W. longitude from Greenwich; the same radius will draw the meridian expressing 140° W. longitude, in like manner: draw the next meridian with the radius CB, set one foot of the compasses in the point *d*, and describe the arcs *aa* and *bb*, then draw lines as before, which will give the point D, the centre of 90° W. longitude; so of all the rest.

The parallels of latitude are drawn in the same manner, with this difference, that the semicircles XX and ZZ must be drawn from the points A and B, the extremities of the equator.

In the manner above described, with great labour and exactness, Mr. Arrowsmith, to whom we are indebted for a part of this article, drew all the meridians and parallels of latitude to every degree on two hemispheres, which laid the foundation of his excellent map of the world.

We shall now proceed to show how the same thing may be done mechanically, both with regard to the globular and stereographic projection.

(1) *The Globular Projection of the Sphere on the Plane of a Meridian.*

Draw the circle WNES, fig. 3, draw the two diameters NS and WE at right angles with each other.

Divide the arc of each quadrant into nine equal parts.

Divide the radii also in the same manner into ninety equal parts each.

The diameter NS is the meridian, and the diameter WE is the equator.

The other meridians are arcs of circles, for each of which, as we have seen, there are three given points through which it must pass, and those are the two poles NS, and a division on the semi-diameter WC, viz. either *a*, *b*, *c*, *d*, *e*, *f*, *g*, or *h*. The centres for these arcs will be in the line CE produced; and the centres for those on the other side, will be on the line CW produced.

For the arc	S*a*N.	the radius	*aa* = 90,61	Of the = parts of which the radius contains 90.
—	S*b*N.	—	*bb* = 92,82	
—	S*c*N.	—	*cc* = 97,32	
—	S*d*N.	—	*dd* = 106	
—	S*e*N.	—	*ee* = 121,1	
—	S*f*N.	—	*ff* = 149,7	
—	S*g*N.	—	*gg* = 215,6	
—	S*h*N.	—	*hh* = 410,7	

And for each of the arcs representing the parallels of lat. also there are three given points; viz. one of the divisions *k*, *l*, *m*, *n*, *o*, *p*, *q*, or *r*, upon the meridian SN, and the two corresponding divisions of the circumference. The centres for these arcs will fall on the line SN, produced both ways, and the following table shows the length of the radius of each equal part, in equatorial degrees, as in the former case.

For the arc

80	*r*	80	the radius	*rr* = 18,44	Of the equal parts of which the radius contains 90.
70	*q*	70	—	*qq* = 39,75	
$66\frac{1}{2}$	A.	$66\frac{1}{2}$	—	A. *Arctic* = 48,19	
60	*p*	60	—	*pp* = 65,3	
50	*o*	50	—	*oo* = 97,71	
40	*n*	40	—	*nn* = 143	
30	*m*	30	—	*mm* = 210	
$23\frac{1}{2}$	T.	$23\frac{1}{2}$	—	T. *Tropic* = 281,4	
20	*l*	20	—	*ll* = 337,5	
10	*k*	10	—	*kk* = 703,5	

(2) *The Stereographic Projection of the Sphere on the Plane of a Meridian.*

Draw a circle NESW, fig. 4, and the two diameters of it at right angles with each other.

Divide the arc of each quadrant into nine equal parts.

From the point E, draw dotted lines to each point of division on the arc WN.

The intersections made by this means on the semidiameter CN, mark a line of semitangents, which must also be set off on the other three semidiameters, CS, CW, and CE.

Draw likewise two dotted lines from E to $23\frac{1}{2}^{\circ}$ and $66\frac{1}{2}^{\circ}$ for the tropic and polar arcs, which must also be set off on the semi-diameter CS.

Each point of intersection on CN, and the corresponding divisions on the arcs WN and EN, are the three points through which the arcs of latitude must pass; and their centres will be in the line NS produced.

Take the radius of the same circle for a scale; divide it into nine equal parts, and each of those parts into ten other parts as before.

The following table exhibits the length in those parts of the radius, which must be taken to describe each respective arc.

For the arc

80	*r* 80	the radius	*rr*	= 15,87	Of the equal parts of which the radius contains 90.
70	*s* 70	—	*ss*	= 32,75	
$66\frac{1}{2}$	A. $66\frac{1}{2}$	—	A. *Arctic*	= 39.19	
60	*t* 60	—	*tt*	= 51,96	
50	*v* 50	—	*vv*	= 75,52	
40	*w* 40	—	*ww*	= 107,3	
30	*x* 30	—	*xx*	= 155,9	
$23\frac{1}{2}$	T. $23\frac{1}{2}$	—	T. *Tropic*	= 207	
20	*y* 20	—	*yy*	= 247,3	
10	*z* 10	—	*zz*	= 510,4	

The two polar points N. S. and the semitangents on CE. mark the three given points through which each meridian line must pass.

The following table exhibits the length of each radius to describe the meridian arcs.

For the arc	N*a*S.	the radius	*aa*	= 91,4	Of the = parts of which the radius contains 90.
—	N*b*S.	—	*bb*	= 95,78	
—	N*c*S.	—	*cc*	= 104	
—	N*d*S.	—	*dd*	= 117,5	
—	N*e*S.	—	*ee*	= 140	
—	N*f*S.	—	*ff*	= 180	
—	N*g*S.	—	*gg*	= 263	
—	N*h*S.	—	*hh*	= 518,3	

(3) *The Globular Projection of the Sphere on the Plane of the Equator.*

On the centre P, fig. 5, draw the circle WN ES, to represent the equator.

Draw the two diameters, WE and NS, at right angles with each other.

Divide the arcs of the four quadrants into nine equal parts: each of the parts will be equal to ten degrees.

Number them from N towards P, 10, 20, 30, 40, 50, &c.

On the centre P draw circles passing through those points of division, which will be the circles of latitude.

For the arctic circle, set off $23\frac{1}{2}^{\circ}$ from P towards N; do the same at N towards P, for the tropic circle.

Through each of those points draw an obscure circle.

Draw diameters from the divisions on one half of the circumference to the corresponding divisions on the opposite one, to represent the meridians, and this will complete the projection.

(4) *The Stereographic Projection of the Sphere on the Plane of the Equator.*

Draw the circle N, W, S, E, fig. 6, and the two diameters at right angles with each other.

Divide the arcs of each of the four quadrants into nine equal parts; subdivide each of those parts into 10 degrees; number those degrees 10, 20, 30, &c.

Draw diameters from the divisions on one side of the circumference to the corresponding divisions on the other, which will represent the meridians.

For the parallels of latitude, project a line of semitangents as directed in the 2d case.

On the centre P describe circles passing through the semitangents, which will complete the diagram.

Note. The foregoing methods of projecting the sphere are the best. There is another method sometimes used, viz. the projection on the plane of the horizon when any assumed place is considered as the centre; but as this method is rarely used, it need not be elucidated.

The orthographic projection is in fact so erroneous, that it ought to be entirely rejected for that purpose, and applied only to dialling.

The gnomonical projection is only applicable to dialling.

We shall now point out the advantage and disadvantage of Mercator's projection.

A method has been found to obviate some of the difficulties attending all the circular projections by one, which, from the person who first used it (though not the inventor), is called Mercator's projection. In this there are none but right lines: all the meridians are equidistant, and continue so through the whole extent; but, on the other hand, in order to obtain the true bearing, so that the compass may be applied to the map (or chart) for the purpose of navigation, the spaces between the parallels of latitudes (which in truth are equal, or nearly so) are made to increase as they recede from the equator in a proportion which, in the high latitudes, becomes prodigiously great.

The great advantages peculiar to this projection are, that every place drawn upon it retains its true bearing with respect to all other places; the distances may be measured with the nicest exactness by proper scales, and all the lines drawn upon it are right lines: for these reasons it is the only projection in drawing maps or charts for the use of navigators. We shall show the method of this kind of projection.

Mercator's or Wright's projection of maps.—Draw the line AB, fig. 7, and divide it into as many degrees as your map is to contain in longitude, suppose 90°. At the extremities A and B raise perpendiculars, to which draw parallel lines at every single, fifth, or tenth degree of the equator, for the meridians; as in the figure, where they are drawn at every tenth degree. This done, put one foot of the compasses in the point A, and extending the other to the point in the first meridian in the equator G; or, for greater exactness, to some more distant point, as B 90; describe the quadrant FB, which divide into nine equal parts, and draw lines from A to each point of the division; or, to avoid scoring the paper, only mark where a ruler cuts the first meridian GH, at every tenth de-

gree's distance. Lastly, because the distances of the parallels from one another are marked, by this means, in the line GH, you must transfer them from that line to the side lines AC, BD, after the following manner: 1. Set one foot of the compasses in A, and extending the other to the first point above G, marked 1, transfer this distance, viz. A 1, to the lines AC, BD, and draw a line parallel to the equator AB, for the tenth parallel 2. Next transfer the distance A 2 into the lines AC, BD, from the 10th parallel to the 20th, which is to be drawn. 3. In the same manner the distances A 3, A 4, A 5, &c. laid off upon the lines AC, BD, from the immediately preceding parallels, viz. 20, 30, 40, &c. will successively point out where the parallels 30, 40, 50, &c. are to be drawn.

This is the geometrical projection, which may also be laid down by means of a scale or table of meridional parts, by the line of secants, &c.

This projection supposes the earth, instead of a globular, to have a cylindrical figure; in consequence of which, the degrees of longitude become of an equal length throughout the whole surface, and are marked out on the map by parallel lines. The circles of latitude also are represented by lines crossing the former at right angles, but at unequal distances. The further we remove from the equator, the longer the degrees of latitude become in proportion to those of longitude, and that in no less a degree than as the secant of an arch to the radius of the circle; that is, if we make one degree of longitude at the equator the radius of a circle; at one degree distant from the equator, a degree of latitude will be expressed by the secant of one degree; at ten degrees distance, by the secant of ten degrees, and so on. A map of the world, therefore, cannot be delineated upon this projection, without distorting the shape of the countries in an extraordinary manner. The projection itself is, however, as we have already observed, very useful in navigation, as it shows the different bearings with perfect accuracy, which cannot be done upon any other map.

We shall now add a more exact method of projecting particular maps, wherein the squares are so projected as to form equal diagonals throughout.

Of the projection of maps of particular parts of the world.—There are several methods of projecting particular parts of the world, we shall notice only two. First, when the meridians and parallels of latitude are right lines.

To project a map of England after this method.—England is situated between 2° E. and 6° 20′ W. from Greenwich, and between 50° and 56° N. lat.

Draw a base line AB, fig. 8, in the middle of which erect the perpendicular CD.

Assume a distance for a degree of lat. and set off as many degrees on CD as are wanted, which in this instance are 6; but as a little space beyond the limits of the country is generally left, set off 7.

Through these points draw lines parallel to AB, which will be parallels of latitude.

Respecting the degrees of longitude it must be observed, that on the equator they would be of the same length as they are on a meridian, but must gradually decrease from thence to 0 at the poles.

The following table exhibits the length in geographical miles, of a degree of longitude for every degree of latitude.

Deg. Lat.	Geograp. Miles.	Deg. Lat.	Geograp. Miles	Deg. Lat.	Geograp. Miles.
0	60,00	31	51,48	61	29,09
1	59,99	32	50,88	62	23,17
2	59,96	33	50,32	63	27,24
3	59,92	34	49,74	64	26,30
4	59,85	35	49,15	65	25,36
5	59,77	36	48,54	66	24,41
6	59,67	37	47,92	67	23,44
7	59,56	38	47,28	68	22,48
8	59,42	39	46,63	69	21,50
9	59,26	40	45,96	70	20,52
10	59,09	41	45,28	71	19.53
11	58,90	42	44,59	72	18,54
12	58,69	43	43,38	73	17,54
13	58,46	44	43,16	74	16,53
14	58,22	45	42.43	75	15,53
15	57,95	46	41,68	76	14,52
16	57,67	47	40,92	77	13,50
17	57,38	48	40,15	78	12.47
18	57,06	49	39,36	79	11,45
19	56,73	50	31,57	80	10,42
20	56,38	51	38,76	81	9,38
21	56,02	52	36,94	82	8,34
22	55,63	53	36,11	83	7,31
23	55,23	54	35,27	84	6,27
24	54,81	55	34,41	85	5,23
25	54,38	56	33,55	86	4,18
26	53,93	57	32,68	87	3,14
27	53,46	58	31,79	88	2,09
28	52,97	59	30,90	89	1,40
29	52,47	60	30,00	90	0,00
30	51,96				

To use this table, divide the assumed degree into sixty parts by a diagonal line, fig. 9: look for the number of miles answering to the degree of lat. 49, which is 39, 36, say 39½, which take off the scale, fig. 9, at *a*, and set off four times from C towards A, and the same from C towards B. The top meridian is 56° of lat. opposite which, in the table, is 33, 55, say 33½, which take from the scale, fig. 9, at *b*, and set off four times from D towards E, and the same from D towards F. Draw the meridian lines to the corresponding divisions at top and bottom, of which 0 0 is the meridian of London.

Second. When the meridians and parallels are curved lines.

To project a map of Europe by this method.—Draw a base line GH, fig. 10, in the middle of which erect the perpendicular JP, and assume any distance for 10° of latitude.

Europe extends from 36° to 72° N. lat.

Let the point J be 30°. from which set off six of the assumed distances to P, which will be the N. pole.

Number the distances 40, 50, 60, &c.

On the centre P, describe arcs passing through the points of division on the line JP, which will be parallels of latitude.

Divide the space assumed for 10° of lat. into 60 parts by a diagonal line, fig. 11.

Look into the foregoing table for the number of miles answering to 30°, which is 51,96, say 52, which take from the scale, fig. 11, at *b*.

Set this distance off on the arc 30, 30, from the centre line JP both ways.

Do the same for 40°, 50°, 60°, &c.

Through the corresponding divisions, on all the arcs, draw curve lines; which will represent the meridians.

Number the degrees of lat. and lon., which will complete the diagram.

MARANTA, *Indian arrow-root*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the eighth order, scitamineæ. The corolla is ringent and quinquefid, with two segments alternately patent. There are five species, all of them herbaceous perennial exotics of the Indies, kept in some hot-houses for curiosity: they have thick, knotty, creeping roots, crowned with long, broad, arundinaceous leaves, ending in points, and upright stalks, half a yard high, terminated by bunches of monopetalous, ringent, five-parted flowers. The root of the galanga is used by the Indians to extract the virus communicated by their poisoned arrows: whence it has derived its name of arrow-root. The arundinacea, or starch plant, rises to two feet, has broad pointed leaves, small white flowers, and one seed. It is cultivated in gardens and in provision grounds in the West Indies; and the starch is obtained from it by the following process: The roots when a year old are dug up, well washed in water, and then beaten in large deep wooden mortars to a pulp. This is thrown into a large tub of clean water. The whole is then well stirred, and the fibrous part wrung out by the hands, and thrown away. The milky liquor being passed through a hair-sieve, or coarse cloth, is suffered to settle, and the clear water is drained off. At the bottom of the vessel is a white mass, which is again mixed with clean water, and drained: lastly, the mass is dried on sheets in the sun, and is pure starch.

MARATTIA, a genus of the cryptogamia filices. The capsules are oval, gaping longitudinally at top, with several cells on each side. There are three foreign species.

MARBLE, in natural history, a genus of fossils, composed chiefly of lime; being bright and beautiful stones, moderately hard, not giving fire with steel, fermenting with, and soluble in, acid, menstrua, and calcining in a slight fire. The word comes from the French marbre, and that from the Latin marmor, of the Greek μαρμαιρειν, to shine, or glitter. See LIME.

The colours by which marbles are distinguished are almost innumerable; but the most remarkable are, 1. The black marble of Flanders. 2. Plain yellow. 3. Yellow with some white veins. 4. Yellow with black dendrites. 5. Yellow with brown figures resembling ruins. 6. Black and yellow. 7. Black and white. 8. Pale yellow, with spots of a blackish-grey colour. 9. Yellow, white, and red. 10. Pale yellow. 11. Olive-colour, with deeper-coloured cross lines, and dendrites. 12. Brownish-red. 13. Flesh coloured and yellow. 14. Common red marble. 15. Crimson, white, and grey. 16. Reddish-brown lumps, on a whitish ground. 17. Bluish-grey. 18. Snowy-white.

The finest solid modern marbles are those of Italy, Blankenburg, France, and Flanders. It has also been lately discovered that very fine marble is contained in some of the western islands of Scotland. Those of Germany, Norway and Sweden, are of an inferior kind, being mixed with a kind of scaly limestone; and even several of those above-mentioned are partly mixed with this substance, though in an inferior degree. Cronstedt, however, mentions a new quarry of white marble in Sweden, which, from the specimens he had seen, promised to be excellent.

The specific gravity of marble is from 2700 to 2800; that of Carriera, a very fine Indian marble, is 2717. Black marble owes its colour to a slight mixture of iron. Mr. Bayen found some which contained five per cent. of the metal; notwithstanding which the lime prepared from it was white, but in time it acquired an ochry, or reddish-yellow colour.

MARBLE, *polishing of*, is performed by first rubbing it well with a free stone, or sand, till the strokes of the axe are worn off, then with pumice-stone, and afterwards with emery.

MARBLING, in general, the painting any thing with veins and clouds, so as to represent those of marble.

Marbling of books or paper is performed thus: Dissolve four ounces of gumarabic into two quarts of fair water; then provide several colours mixed with water in pots or shells, and with pencils peculiar to each colour, sprinkle them by way of intermixture upon the gum water, which must be put into a trough, or some broad vessel; then with a stick curl them, or draw them out in streaks, to as much variety as may be done. Having done this, hold your book or books close together, and only dip the edges in, on the top of the water and colours, very lightly; which done, take them off, and the plain impression of the colours in mixture will be upon the leaves; doing as well the ends as the front of the book in the like manner.

Marbling books on the covers is performed by forming clouds with aquafortis, or spirit of vitriol mixed with ink, and afterwards glazing the covers.

MARCGRAVIA, a genus of the polyandria monogynia class of plants, the corolla whereof consists of a single petal, of a conico-oval figure; and its fruit is a globose berry, with a single cell, containing a great number of very small seeds. There is one species, a shrub of the West Indies.

MARCHANTIA, a genus of the cryptogamia class of plants, the corolla of which is monopetalous, turbinated, and shorter than the cup; in the lower cavity of which there are contained several naked seeds, of a roundish but compressed figure. There are seven species, five of them British.

MARCIONITES, christians in the second century, thus denominated from their leader Marcion, who maintained that there were two principles or gods, a good and a bad one.

MARCOSIANS, a sect of christians in the second century, so called from their leader Marcus, who represented the supreme God as consisting not of a trinity, but a quaternity, viz. the ineffable, silence, the father, and truth.

MARE. See EQUUS.

MARGARITERIA, a genus of the diœcia octandria

class and order. The male calyx is four-toothed; corolla four-petalled. Female calyx and corolla as above; styles four or five. There is one species, a native of Surinam.

MARICA, a genus of the trigynia monogynia class and order. The calyx is six-parted; stigma petal-form, trifid; capsule three-celled, inferior. There is one species, a fleshy bulb of Guiana.

MARILLA, a genus of the class and order polyandria monogynia. The calyx is five-leaved; corolla five-petalled; capsule four-celled, many seeded; stigma simple. There is one species, a native of the West Indies.

MARK, *knights of St.*, an order of knighthood in the republic of Venice, under the protection of St. Mark the evangelist. The arms of the order are, gules, a lion winged or, with this device, "Pax tibi Marce evangelista." This order is never conferred but on those who have done signal service to the commonwealth.

Mark or Marc, also denotes a weight used in several states of Europe, and for several commodities, especially gold and silver. In France, the mark is divided into 8 oz. or 64 drachms, or 192 derniers or pennyweights, or 160 esterlines, or 300 mailles, or 640 felins, or 4608 grains. In Holland the mark-weight is also called troy-weight, and is equal to that of France. When gold and silver are sold by the mark, it is divided into 24 caracts.

Mark is also used in England for a money of account, and in some other countries for a coin. The English mark is two-thirds of a pound sterling, or 13*s.* 4*d.* and the Scotch mark is of equal value in Scotch money of account. The mark-lubs, or lubeck-mark, used at Hamburgh, is also a money of account, equal to one-third of the rix-dollar, or to the French livre: each mark is divided into 16 sols-lubs. Mark-lubs is also a Danish coin equal to 16 sols-lubs. Mark is also a copper and silver coin in Sweden.

MARKET. A market is less than a fair, and is commonly held once or twice a week. According to Bracton, one market ought to be distant from all others at least six miles and a half and a third of a half: but no market is to be kept within seven miles of the city of London: but all butchers, victuallers, &c. may hire stalls and standings in the flesh-markets there, and sell meat and other provisions, four days in a week. Every person who has a market is entiled to receive toll for the things sold in it; and, by ancient custom, for things standing in the market, though nothing be sold: but by keeping a market in any other manner than it is granted, or extorting of tolls or fees where none are due, they may be forfeited.

In London every shop in which goods are exposed publicly to sale, is market overt for such things only as the owner professes to trade in: though if the sale is in a warehouse and not publicly in the shop, the property is not altered. But if goods are stolen from one, and sold out of the market overt, the property is not altered, and the owner may take them wherever he finds them. 5 Rep. 83.

If a man buy his own goods in a market, the contract shall not bind him, unless the property had been previously altered by a former sale.

MARLE. A mixture of carbonat of lime and clay, in which the carbonat considerably exceeds the other ingredient, is called marle. Its structure is earthy. Opaque, sometimes in powder. Specific gravity from 1.6 to 2.877. Colour usually grey, often tinged with other colours. Effervesces with acids. Some marles crumble into powder when exposed to the air; others retain their hardness for many years. Marles may be divided into two varieties: 1. Those which contain more silica than alumina. 2. Those which contain more alumina than silica. Mr. Kirwan has called the first of these siliceous, the second argillaceous marles. Attention should be paid to this distinction when marles are used as a manure.

Marle, *bituminous*, is found in different parts of Germany. Colour greyish or brownish black. Found massive. Shistoes. Plates flat or waved. Opaque. Feels soft. Easily broken. Moderately heavy. Effervesces with acids. Burns before the blowpipe, leaving black scoriæ.

MARLINS, in artillery, are tarred white skains, or long wreaths or lines of untwisted hemp, dipped into pitch or tar, with which cables and other ropes are wrapped round, to prevent their fretting and rubbing in the blocks or pulleys through which they pass. The same serves in artillery upon ropes used for rigging gins, usually put up in small parcels called skains.

MARMOTTE. See Mus.

MARQUE. See Letters *of Marque*.

MARQUETRY, or Inlaid work, is a curious work composed of several fine hard pieces of wood, of various colours, fastened in thin slices on a ground, and sometimes enriched with other matters, as silver, brass, tortoise-shell, and ivory; with these assistances the art is now capable of imitating any thing, whence it is by some called the art of painting in wood.

The ground on which the pieces are to be arranged and glued is usually of well-dried oak or deal; and is composed of several pieces glued together, to prevent its warping. The wood to be used in marquetry is reduced into leaves of the thickness of a line, or the 12th part of an inch, and is either of its natural colour, or stained, or made black to form the shades by other methods: this some perform by putting it in sand heated very hot over the fire; others by steeping it in lime-water and sublimate; and others in oil of sulphur. The wood being of the proper colours, the contours of the pieces are formed according to the parts of the design they are to represent: this is the most difficult part of marquetry, and that which requires the most patience and attention.

The two chief instruments used in this work are a saw and a wooden vice, which has one of its chaps fixed, and the other moveable; which is open and shut by the foot, by means of a cord fastened to a treadle.

MARQUIS, a title of honour, next in dignity to that of duke, first given to those who commanded the marches, that is, the borders and frontiers of countries.

Marquises were not known in England till the reign of king Richard II. and the year 1337.

MARRIAGE, a contract, both civil and religious, between a man and a woman.

Taking marriage in the light of a civil contract, the law treats it as it does all other contracts: allowing it to be good and valid in all cases where the parties, at the time of making it, were, in the first place, willing to contract; secondly, able to contract; and, lastly, actually

did contract in the proper forms and solemnities required by law. 1 Black. 433.

MARROW. See ANATOMY.

MARRUBIUM, *white horehound*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillatæ. The calyx is salver-shaped, rigid, and ten-striated; the upper lip of the corolla bifid, linear and straight. There are 11 species, the most remarkable of which is the vulgar, a native of Britain, growing naturally in waste places, and by way-sides near towns and villages, but not common. It has a strong and somewhat musky smell, and bitter taste. It is reputed attenuant and resolvent; an infusion of the leaves in water, sweetened with honey, is recommended in asthmatic and phthisical complaints, and most other diseases of the breast and lungs.

MARS, in astronomy, one of the superior planets, moving round the sun in an orbit between those of the earth and Jupiter. See ASTRONOMY.

MARSHAL, in its primary signification, means an officer who has the command or care of horses; but it is now applied to officers who have very different employments, as earl-marshal, knight-marshal, or marshal of the king's house, &c.

MARSHAL *of the king's bench*, an officer who has the custody of the king's bench prison in Southwark. This officer is obliged to give his attendance, and to take into his custody all persons committed by that court.

MARSHAL *of the exchequer*, an officer to whom that court commits the king's debtors.

MARSHALLEA, a genus of the class and order syngenesia polygamia æqualis, little known.

MARSHALLING a coat, in heraldry, is the disposal of several coats of arms belonging to distinct families, in one and the same escutcheon or shield, together with their ornaments, parts, and appurtenances.

MARSHALSEA-COURT, is a court of record, originally instituted to hear and determine causes between the servants of the king's household and others within the verge of the court, and has jurisdiction of things within the verge of the court, and of pleas of trespass, where either party is of the king's family; and of all other actions personal, wherein both parties are the king's servants; but the court has also power to try all personal actions, as debt, trespass, slander, trover, action on the case, &c. between party and party, the liberty whereof extends 12 miles about Whitehall.

The judges of this court are the steward of the king's household, and high marshal for the time being; the steward of the court, or his deputy, is generally an eminent counsel.

If a cause of importance is brought in this court, it is generally removed into the court of king's bench or common pleas by a habeas corpus cum causa.

MARSILEA, a genus of the cryptogamia class of plants, without any corolla or cup: the antheræ are four, and placed on an obtusely conic body; the fruit is of a roundish figure, consisting of four cells, in each of which are contained several roundish seeds. There are three species.

Under this genus are comprehended the salvinia of Micheli, and pilularia of Dillenius.

MARTIAL LAW, is the law of war, which entirely depends on the arbitrary power of the prince, or of those to whom he has delegated it. For though the king can make no laws in time of peace without the consent of parliament, yet in time of war he uses an absolute power over the army.

MARTIN. See HIRUNDO, and MUSTELA.

MARTLETS, in heraldry, little birds represented without feet, and used as a difference or mark of distinction for younger brothers.

MARTNETS, in a ship, small lines fastened to the leech of a sail, reeved through a block on the topmast-head, and coming down by the mast to the deck. Their use is to bring the leech of the sail close to the yard to be furled.

MARTYNIA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is quinquefid; the corolla ringent, the capsule ligneous, covered with a bark, with a hooked beak, trilocular, and bivalved. There are 60 species, tender, herbaceous, flowery, plants of South America.

MARYGOLD. See CALENDULE; and for MARSH-MARYGOLD, see CALTHA.

MASON, a person employed under the direction of an architect, in the raising of a stone building. See ARCHITECTURE.

MASSETER. See ANATOMY.

MASSICOT, a name given to the yellow oxide of lead, as minium is applied to the red oxide.

MASSONIA, a genus of the class and order hexandria monogynia. The corolla is inferior, with 6-parted border; filaments on the neck of the tube; capsule 3-winged, 3-celled, many-seeded. There are four species, bulbs of the Cape.

MAST, in naval architecture, a large timber in a ship, for sustaining the yards, sails, &c.

In large vessels there are four masts, viz. the mainmast, foremast, mizenmast, and bowsprit. The mainmast is the principal one, standing in the middle of the ship: its length, according to some, should be $2\frac{1}{2}$ that of the midship-beam. Others give the following rule for finding its length, viz. multiply the breadth of the ship, in feet, by 24; from the product cut off the last figure towards the right hand, and the rest will be the length required. Thus suppose the length of the midship-beam was 30 feet; then $30 \times 24 = 720$, from which cutting off the last figure, there remains 72 feet for the length of the mainmast. And as for the thickness of the mainmast, it is usual to allow an inch to every yard in length. See SHIP-BUILDING.

MASTER AND SERVANT. In London and other places the mode of hiring is by what is commonly called a month's warning or a month's wages: that is, the parties agree to separate on either of them giving to the other a month's notice for that purpose; or, in lieu thereof, the party requiring the separation to pay, or give up, a month's wages. But if the hiring of a servant is general, without any particular time specified, it will be construed to be a hiring for a year certain; and in this case if the servant departs before the year, he forfeits all his wages. Noy, Max. 107. And where a servant is hired for one year certain, and so from year to year as long as

both parties shall agree, and the servant enters upon a second year, he must serve out that year, and is not merely a servant at will after the first year. If a woman servant marries she must nevertheless serve out her term; and her husband cannot take her out of her master's service.

If a servant is disabled in his master's service by an injury received through another's default, the master may recover damages for loss of his service. And also a master may not only maintain an action against any one who entices away his servant, but also against the servant; and if without any enticement a servant leaves his master without just cause, an action will lie against another who retains him with a knowledge of such departure.

A master has a just right to expect and exact fidelity and obedience in all his lawful commands; and to enforce this he may correct his servant in a reasonable manner, but this correction must be to enforce the just and lawful commands of the master. Bul. N. P. 18.

In defence of his master a servant may justify assaulting another; and though death should ensue it is not murder, in case of any unlawful attack upon his master's person or property.

Acts of the servant are, in many instances, deemed acts of the master; for as it is by indulgence of law that he can delegate the power of acting for him to another, it is just he should answer for such substitute, and that his acts being pursuant to the authority given him, should be deemed the acts of his master. 4 Bac. Abr. 583. If a servant commits an act of tresspass by command or encouragement of his master, the master will be answerable; but in so doing his servant is not excused, as he is bound to obey the master in such things only as are honest and lawful.

If a servant of an inkeeper robs his master's guest, the master is bound to make good the loss. Also, if a waiter at an inn sells a man bad wine, by which his health is impaired, an action will go against the master: for his permitting him to sell it to any person is deemed an implied general command. 1 Black. 430. In like manner if a servant is frequently permitted to do a thing by the tacit consent of his master, the master will be liable, as such permission is equivalent to a general command.

If a servant is usually sent upon trust with any tradesman, and he takes goods in the name of his master upon his own account, the master must pay for them: and so likewise if he is sent sometimes on trust, and other times with money; for it is not possible for the tradesman to know when he comes by the order of his master, and when by his own authority, or when with and without money. 1 Str. 506. But if a man usually deals with his tradesmen himself, or constantly pays them ready money, he is not answerable for what his servant may take up in his name; for in this case there is not, as in the other, any implied order to trust him. Or if the master never had any personal dealings with the tradesman, but the contracts have always been between the servant and the tradesman, and the master has regularly given his servant money for payment of every thing had on his account, the master shall not be charged. Esp. N. P. 115. Or if a person forbids his tradesmen to trust his servant on his account, and he continues to purchase upon credit, he is not liable. The act of a servant, though he has quitted his master's service, has been held to be binding upon the master, by reason of the former credit given him on his master's account, and it not being known to the party trusting that he was discharged. 4 Bac. Abr. 586.

The master is also answerable for any injury arising by the fault or neglect of his servant when executing his master's business, 6 T. R. 659: but if there is no neglect or default in the servant the master is not liable. Esp. Rep. 533.

If a smith's servant lames a horse whilst shoeing him, or the servant of a surgeon makes a wound worse, in both these cases an action for damages will lie againt the master, and not against the servant. But the damage must be done while the servant is actually employed in his master's service, otherwise he is liable to answer for his own misbehaviour or neglect.

A master is likewise chargeable if his servant casts any dirt, &c. out of the house into the common street; and so for any other nuisance occasioned by his servants, to the damage or annoyance of any individual, or the common nuisance of his majesty's people. Lord Raym. 264.

A servant is not answerable to his master for any loss which may happen without his wilful neglect; but if he is guilty of fraud or gross negligence, an action will lie against him by his master.

A master is not liable in trespass for the wilful act of his servant; as by driving his master's carriage against another; done without the direction or assent of his master, no person being in the carriage when the act was done. But he is liable to answer for any damage arising to another from the negligence or unskilfulness of his servant acting in his employ. M'Manus v. Crickett, Mich. 41 G. III.

Master of arts, is the first degree taken up in foreign universities, and for the most part in those of Scotland, but the second in Oxford and Cambridge; candidates not being admitted to it till they have studied seven years in the university.

Master in chancery. The master in chancery are assistants to the lord chancellor and master of the rolls; of these there are some ordinary, and others extraordinary: the masters in ordinary are 12 in number, some of whom sit in court every day during the term, and have referred to them interlocutory orders for stating accounts, and computing damages and the like; and they also administer oaths, take affidavits, and acknowledgments of deeds and recognizances. The masters extraordinary are appointed to act in the country, in the several counties of England, beyond 10 miles distant from London; by taking affidavits, recognizances, acknowledgments of deeds, &c. for the ease of the suitors of the court.

Master of the faculties, an officer under the archbishop of Canterbury, who grants licences and dispensations.

Master of the horse, a great officer of the crown, who orders all matters relating to the king's stables, races, breed of horses, and commands the equerries and all the other officers and tradesmen employed in the king's stables. His coaches, horses, and attendants, are the king's, and bear the king's arms and livery.

general consideration of what is usually denominated animal and vegetable diet.

Master of the rolls, is an assistant to the lord chancellor of England in the high court of chancery; and in his absence hears causes there, and gives orders. His salary is 1200*l.* per annum.

Master of a ship, the same with captain in a merchantman; but in a king's ship he is an officer who inspects the provisions and stores, and acquaints the captain with what is not good, takes particular care of the rigging and of the ballast, and gives directions for stowing the hold; he navigates the ship under the directions of his superior officers; sees that the log and log-book are duly kept; observes the appearance of coasts; and notes down in his journal any new shoals or rocks under water, with their bearing and depth of water, &c.

Master at arms, in a king's ship, an officer who daily, by turns, as the captain appoints, is to exercise the petty officers and ship's company; to place and relieve sentinels; to see the candles and fire put out according to the captains orders; to take care the small arms are kept in good order, and to observe the directions of the lieutenant at arms.

MASK, in field fortification: it sometimes happens that a ditch or fosse must be dug in an exposed situation; in this case it will be absolutely necessary for the artificers and workmen to get under cover by means of masking themselves in such a manner as to answer the double purpose of executing their immediate object, and of deceiving the enemy with respect to the real spot they occupy.

To effect the latter purpose several masks must be hastily thrown up, whilst the men are employed behind one; by which means the enemy will either mistake the real point, or be induced to pour his fire in several directions, and thus weaken its effect.

A mask is generally six feet high. Bags made of wad or wool are too expensive on these occasions; nor are gabions, stuffed with fascines, seven or eight feet high, to be preferred; for if the fascines are tied together they will leave spaces between them in the gabions; and if they are not bound together, they will be so open at top as to admit shot, &c.

In order to obviate these inconveniences the following method has been proposed: Place two chandeliers, each seven feet high and two broad, between the uprights, after which fill up the vacant spaces with facines nine feet high, upon six inches diameter. One toise and a half of epaulement will requre two chandeliers and 60 fascines to mask it.

The engineer, or artillery officer, places himself behind this mask, and draws his plan.

As you must necessarily have earth, &c. to complete your work, these articles may be brought in shovels, sacks, or baskets; and if the quarter whence you draw them should be exposed to the enemy's fire, cover that line, as well as the line of communication, between the trenches, or the parallels, with a mask.

If you cannot procure earth and fascines, make use of sacks stuffed with wool, &c. and let their diameters be three feet, and their length likewise three; and let the outside be frequently wetted to prevent them from catching fire.

MASTOIDES. See Anatomy.

MATCH, a kind of rope slightly twisted, and prepared to retain fire for the uses of artillery, mines, fireworks, &c. It is made of hempen tow, spun on the wheel like cord, but very slack; and is composed of three twists, which are afterwards again covered with tow, so that the twists do not appear: lastly, it is boiled in the lees of old wines. This, when once lighted at the end, burns on gradually and regularly, without ever going out, till the whole is consumed: the hardest and driest match is generally the best.

Match, *quick*, used in artillery, is made of three cotton strands drawn into lengths, and put into a kettle just covered with white-wine vinegar, and then a quantity of saltpetre and mealed powder is put into it, and boiled till well mixed. Others put only saltpetre into water, and after that take it out hot, and lay it into a trough with some mealed powder, moistened with some spirits of wine, thoroughly wrought into the cotton by rolling it backwards and forwards with the hands; and when this is done they are taken out separately, drawn through mealed powder, and dried upon a line.

MATERIA MEDICA. "The materia medica (says Dr. Darwin) includes all those substances which may contribute to the restoration of health." If, however, medicine be defined the art of *preventing*, as well as of curing, diseases, the science of which we are now to treat ought, by consequence, to comprehend the preservatives of living existence, as well as the restoratives of healthy action. Instead, therefore, of restricting this article to the mere enumeration and discussion of drugs, we shall, in the first place, introduce some general remarks on those substances which are employed as articles of diet or food.

PART I.

DIETETICS.

Organic life appears to be influenced and supported by two leading principles: 1st, fibrous excitation; and, 2dly, the substitution of nutritious particles, in place of those which are constantly dissipated or abraded. The power by which this last object is effected has been denominated by the author of Zoonomia, animal appetency. The principal and prime organs by which it is exerted, or the media through which new matter is originally communicated, are those which are termed the digestive and assimilating; it has, however, recently been conjectured that the organs of digestion are not the sole organs of nutrition, but that both the external surface of the body, and likewise the lungs, are media for the admission into the system of proper nutrative matter. Accordingly we find the class nutrientia, in the materia medica of the author just quoted, to comprehend not merely those substances which are received into the stomach as food, but also the matter which is taken into the lungs in the act of respiration, as likewise air, water, and other substances that may be applied naturally or artificially to the outer skin. To inquire into the grounds upon which this doctrine is established, that the lungs, the stomach, and the surface of the body, each affords instruments in common of actual nutrition, does not fall within the province of the present article. See Physiology. It will be proper here to confine ourselves to the

general consideration of what is usually denominated animal and vegetable diet.

OF ANIMAL FOOD.

That man is designed by nature for a mixture of animal and vegetable food, is obvious from the structure of his organs, both of mastication and digestion. That the flesh of animals contains more nutritive matter, and that it stimulates the absorbent and secerning vessels more powerfully, than vegetable aliment, is demonstrated by the superior warmth and strength which in a state of health we experience after a meal of flesh than of vegetables: of the former (animal flesh), that, in general, which is of the darkest colour, contains more nutritive matter, and stimulates our vessels with more energy, than the white kinds: indeed the flesh of those animals which are carnivorous, or which live entirely on animal food, seldom enters into the diet of European, or civilized nations. The greater stimulating virtue of this kind of food has been attributed to the greater quantity which it has been supposed to contain of volatile alkali. Dr. Darwin, however, properly questions whether it is not rather the elements only of this principle that are contained even in the strongest dark-coloured animal flesh.

Next in strength to the flesh of carnivorous animals ought to rank that of those animals when killed after full growth, the young of which afforded a softer, whiter, more digestible, but less nutritious, food, such as the sheep, the bullock, the hog, and likewise several of the shell-fish, as lobsters, crabs, muscles, &c. in which class may likewise be enumerated several fish that are destitute of scales or shells, as ell, barbolt, tench, smelt, turtle, turbot. Of the fowl kind the bustard, wood-pecker, starling, sparrow, goose, duck, and lapwig, ought to be arranged in this second class. These, with a due mixture of vegetable aliment, constitute the best kinds of food for healthy and athletic individuals, whose digestion is powerful, and who have a firm fibre.

The flesh of the young animals, as of lamb, veal, and ucking pigs, afford a less stimulating and nutritious, but more digestible food: these meats are consequently most congenial to persons of less muscular energy, who have more feeble powers of digestion, and who accustom themselves to but little exercise: they are adapted to the hypochondriac and should be principally used as aliment by individuals who are disposed to those kind of affections which have received the vulgar and indiscriminate appellation of scorbutic.

A still milder, but, in the same proportion, less nutritive food, is furnished by the white meats, such as the domestic fowl, partridge, pheasant, and their eggs, with oysters and young lobsters. These, from their bland and unacrimonious nature, are generally allowed to convalescents from acute diseases: they are peculiarly suitable to very weak stomachs, and ought in general to form the first articles in the diet of females after childbirth. The major part of the river fish which have scales, as pike, perch, and gudgeon, are possessed of very inferior nutritive faculty.

OF MILK AND ITS PRODUCTS.

Milk partakes of the properties of both animal and vegetable aliment: it may be separated by rest or by agitation into cream, buttermilk, whey, and curd. The cream is easier of digestion by the adult stomach, on account of its containing less of the caseous, or cheesy part; it is likewise on this account more nutritive. Butter contains still more nutriment, and is likewise, if not taken to excess, exceedingly easy of digestion, and is by no means calculated to generate unpleasant humours in the body. If given without any separation of its principles by artificial preparation, it might be admitted into the diet of infancy with much greater propriety than other articles which are employed with less apprehension of injury. Buttermilk is agreeable, bland, and gently nutritive. Whey is the least nutritious, and most easy of digestion. It is on this account ordered with the utmost propriety to those invalids whose constitutions have been rendered too irritable to bear the stimulus of more solid and nutritive aliment. Cheese is of various kinds, arising principally from the greater or less quantity of cream that it contains. Those cheeses which are broken to pieces in the mouth with most readiness are, for the most part, most easy of digestion, and most nutritive. Many kinds of cheeses are a considerable time in undergoing chemical change in the stomach; and on this account, although difficult of digestion, do not disagree with weak stomachs. Dr. Darwin observes that he has seen toasted cheese vomited up a whole day after it was eaten, without having become perceptibly altered, or given any uneasiness to the patient.

New cow's-milk is the food of infants, and is by far the best substitute for the milk of the mother, if this last be not afforded in sufficient quantity or quality by the parent, which, however, is seldom the case. The stomachs of children abound with acidity; and milk, which is always curdled before it is assimilated, is consequently digested with more facility in the earlier than in the more advanced periods of life. It is on this account likewise that certain vegetable substances, which have a great tendency to acidity, are exceedingly injurious to the infantile stomach. See the article Infancy.

OF VEGETABLE FOOD.

The seeds, roots, leaves, and fruits, of plants, particularly the two former, constitute a very material part of the food of mankind. According to the opinion of Dr. Cullen, and other physiologists, the quantity of actual nourishment that these contain, is in proportion to the quantity of sugar that they can be made to produce; it is imagined that the mucilage which the farinaceous seeds contain, is changed in the granary to starch; and that this starch, in the processes to which the seeds are afterwards subjected, or by digestion in the stomach, is at length converted into saccharine principle. See Physiology. The farinaceous seeds are wheat, barley, oats, rye, millet, maize or Indian corn, &c. The roots of this class are the sugar-root, the common carrot, beet, and polypody. Those with less of the saccharine principle, and which afford a tender farina, are the turnip-rooted cabbage, the parsnip, parsley root, asparagus, turnips, potatoes, &c.; all of which, if less nutritive, are better suited to weakly organs of digestion than those in which the sugar is more abundant.

Other vegetables contain oil, sugar, mucilage, or acid, in various proportions, diluted with much water: these

are but slightly nutrimental; and are, for the most part, injurious to delicate stomachs especially, unless taken with moderation; these are the apple, pear, plum, apricot, nectarine, peach, strawberry, grape, orange, melon, cucumber, dried figs, raisins, and a great variety of other roots, seeds, leaves, and fruits. Of these it may be observed generally, that those which are cold, watery, and sweet, are most calculated to prove indigestible, and consequently injurious.

DIFFERENT METHODS OF DRESSING VICTUALS.

Various modes of preparing and dressing both animal and vegetable articles of food have been contrived, in order to render them more palatable, and better adapted to the stomach. By boiling, animal flesh is, in some measure, deprived of its nourishing juice, which is with more or less facility given out to, and incorporated with, the broth: this last then contains the most nutritious part of the meat; but unless stronger than is ordinarily used, it is too diluted to admit of an easy digestion. Broths likewise have a remarkable tendency to acidity, particularly when made from the flesh of young animals, as of lamb and veal; and on this account also are much less congenial to weak stomachs than is generally imagined. The various jellies, which contain the gelatinous and nutritive, to the exclusion of the fibrous part of animal flesh, are in general much more suitable to the invalid and the convalescent than either broths or soups. Perhaps the most eligible mode of preparing animal food is by the process called stewing; for by this process its nitritious and substantive parts are concentrated and preserved. It is scarcely necessary to observe that the gravy of boiled meat contains its notritive parts in a state of concentration; it is digested with facility; and gravy is therefore the best mode of giving animal food to very young infants.

Roasting preserves the nutritive part of flesh from dissipation in a greater degree than boiling: and it has been asserted by an observant author (Dr. Willich) that "one pound of roast meat is, in real nourishment, equal to two or three pounds of boiled meat." It ought however to be noticed, that the fat of meat treated in this way has undergone some degree of chemical decomposition from its exposure to heat, and is in consequence more oppressive to delicate stomachs, and generally less salutary, than that of boiled flesh. Both baking and frying are upon similar principles improper methods of preparing animal food. Smoked meats, as prepared hams, are hard of digestion. They should only be taken in small quantities, and rather as condiment than food.

The art of cookery, as applied to vegetable substances, is principally useful in destroying the native acrimony, and rendering the texture softer of some, and by converting the acerb juices of others into saccharine matter. The boiling of cabbage, of asparagus, &c. are examples of the one, the baking of unripe pears is an instance of the other. The above are all chemical processes; they are too familiar to need description.

Another mode by which the nourishment of mankind is facilitated, is the mechanic art of grinding farinaceous seeds into powder; and, in some instances, exposing them afterwards to a fermenting process, as in the making of bread, and then to the action of fire by baking or boiling. The mill-stones, by which the process of grinding is effected, have been quaintly termed the artificial teeth of society. It has been suggested by Dr. Darwin, that "some soft kinds of wood, especially when they have undergone a kind of fermentation, and become looser, might, by being subjected to the action of the mill-stones, be probably used as food in the times of famine. Nor is it improbable," continues our ingenious speculator, "that hay which has been kept in stacks, so as to undergo the saccharine process, may be so managed by grinding and by fermentation with yeast, like bread, as to serve in part for the sustenance of mankind in times of great scarcity. Dr. Priestley gave to a cow, for some time, a strong infusion of hay in large quantities for drink, and found that she produced during this treatment above double the quantity of milk. Hence if bread cannot be made from ground hay, there is great reason to suspect that a nutritive beverage may be thus prepared, either in its saccharine state, or fermented into a kind of beer. In times of great scarcity there are other vegetables, which, though not in common use, would most probably afford wholesome nourishment, either by boiling them, or drying and grinding them, or by both those processes in succession. Of these perhaps are the tops and barks of all those vegetables which are armed with thorns or prickles, as gooseberry-trees, holly, gorse, and perhaps hawthorn. The inner bark of the elm-tree makes a kind of gruel; and the roots of fern, and probably very many other roots, as of grass and clover taken up in winter, might yield nourishment, either by boiling or baking, and separating the fibres from the pulp by beating them; or by getting only the starch from those which possess an acrid mucilage, as the white betony. And the alburnum of perhaps all trees, and especially of those which bleed in spring, might produce a saccharine and mucilaginous liquor, by boiling it in the winter or spring."

OF DRINK.

"Water," says Dr. Darwin, "must be considered as a part of our nutriment, because so much of it enters the composition of our fluids; and because vegetables are believed to draw almost the whole of their nourishment from this source." It may, however, be questioned whether pure elementary water taken into the stomach acts upon the system as a nutrimental matter in any other mode than by procuring the solution, and thus facilitating assimilation, of solid aliment.

Water is the natural and proper drink of man. It is the basis of all other liquids; and the larger proportion of water that enters their composition, the more easily, in a state of health, and provided proper food has been taken, are the solution and digestion of such food effected.

This fluid, however, is never or seldom taken in a state of entire purity. Even in nature's laboratory it is invariably impregnated with foreign substances; and it is this admixture of extraneous matter which constitutes its varieties. Thus we have snow water, rain water, spring water, river water, and water from lakes, wells, and swamps, each possessing their individual characteristics.

Spring water is, in general, most free from impurities; it is, however, less suited for drink than the water of rivers, as it almost constantly contains calcareous, or sa-

line ingredients. The calcareous earth dissolved in the water of many springs, has been supposed indeed by Dr. Darwin to contribute to our nourishment in the manner that lime proves useful in agriculture. This principle, however, is not perhaps fully established; and we believe that too much stress has by theorists in general been laid on the specific qualities of water, as modifying both the bodily and intellectual character of individuals and nations. The cretinism and fatuity of the Alpine valleys were formerly attributed to the waters of these countries, but are now more commonly, and we believe more justly, referred to constitutional propensity, innutritious food, and a humid unhealthy atmosphere.

That water however possesses great varieties, according to the nature of the soil and situation of the place in which it is produced or contained, is undeniable; and we shall here extract part of what is observed on these varieties by an attentive and judicious observer.

"*Spring water*," says Dr. Willich, "originates partly from that of the sea, which has been changed into vapours by subterraneous heat, and partly from the atmosphere. As it is dissolved and purified in a variety of ways before it becomes visible to us, it is lighter and purer than other waters.

"*Well water*. Wells opened in a sandy soil are the purest. The more frequently a well is used, the better; for the longer water stands unmoved, the sooner it turns putrid.

"*River water* is more pure and wholesome if it flows over a sandy and stony soil, than if it passes over muddy beds, or through towns, villages, and forests: water is rendered foul by fish, amphibious animals, and plants.

"*Lake water* much resembles river water, but being less agitated it is more impure. The water which, in cases of necessity, is obtained from swamps and ditches, is the worst of all; because a great variety of impurities are there collected, which, in a stagnant and soft soil, readily putrify.

"*Rain water* is also impure, as it contains many saline and oily particles, soon putrefies, and principally consists of the joint exhalations of animals, vegetables, and minerals, of an immense number and variety of small insects and their eggs, seeds of plants, and the like. Rain water is particularly impure in places filled with many noxious vapours; such as marshy countries, and large manufacturing towns, where the fumes of metallic and other substances are mixed with rain. In high and elevated situations, at a distance from impure exhalations, if no strong winds blow, and after a gentle shower, rain water is then purest. In summer, however, on account of the copious exhalations, rain water is most objectionable.

"*Snow water* possesses the same properties as rain water, but is purer; both are soft, that is, without so many mineral and earthy particles as spring, well, and river waters. *Hail water*, being produced in the higher regions of the atmosphere, is still purer from its congelations. Lastly, *dew*, as it arises from the evaporation of various bodies of the vegetable and animal kingdoms, is more or less impure, according to the different regions and seasons."

Of the different kinds and qualities of fermented and spirituous liquors, it does not fall within the compass of the present article to treat. They all consist of water as their base or vehicle, of more or less alcohol or ardent spirit according to their different degrees of strength, of sugar, and of the particular ingredient by which their nature is determined; such as the grape in wine, the apple and pear in cyder and perry, the malt and hop in beer, &c. &c. (See the respective articles in their alphabetical order.) It is only necessary here to observe, that, with few exceptions, fermented liquors, when immoderately taken, are more detrimental than elementary fluids in proportion to the quantity that they contain of alcohol, or ardent spirit.

With respect to the China tea and the coffee-berry, which have lately come into such general use, we believe them to be much less injurious to the animal economy than some theorists have been disposed to conjecture. In excess, however, and when indulged in as substitutes for, and, as is sometimes the case, almost to the exclusion of, nourishing diet, they are highly deleterious, as they tend to the induction of a morbidly irritable condition of the nervous system. It deserves to be remarked, that these stimuli do not, like alcohol, produce those formidable, and often irremediable, disorders, affections of the liver, dropsy, and apoplexy.

An enumeration of spices (which, like spirituous liquors, are used as articles of diet with too great freedom) will be found under the head Aromatics, in a subsequent section of this article.

PART II.

MEDICINALS.

We now proceed to the second division of our subject, or to the consideration of the materia medica in its more ordinary and limited signification.

Various divisions and modes of classification of those articles which are used in medicine, have been proposed and adopted by different authors. Some systematic writers arrange the articles of the materia medica according to their alphabetical order: others have taken for the basis of their arrangement the more sensible properties of drugs, as detected by the taste; thus reducing medicines to the different heads of bitterness, sweetness, astringency, acidity, &c.: while some have been regulated in their classification of medicinal articles, by their characters as objects in natural history. "As, however, the study of the materia medica is merely the study of the medicinal properties of certain substances, it is evident that the method of arranging them as they agree in producing effects on the living system is the one best calculated to fulfil all its objects." Murray.

Among the different plans of arrangment which have been framed on this principle, that adopted by Mr. Murray, in his late work on the materia medica, appears liable to the fewest objections. It is founded on the principle of Dr. Brown, "that medicines operate by stimulating the living fibre, or exciting it into motion." See the article Brunonian System. This proposition, however, was received and applied by its author in too unlimited a sense. In the first place, stimulation differs not merely in *degree*, but also in *kind*; or, in other words, one given medicine cannot by any regulation of its quantity be made to produce the same effects which result from the agency of another; some are more diffusible and transient, others more slow and permanent in

their action; some affect the universal system in almost an equal degree, while the operation of others is more especially, and in some instances almost exclusively, directed to a certain part. They have all likewise properties peculiar to themselves.

But beside this general and very important modification of the Brunonian materia medica, it is necessary further to take into view, that medicines sometimes appear to display their agency even on the living body almost entirely upon chemical or mechanical principles; these last modes of operation, although less common and extensive than were supposed in the ancient systems of medicine, must still be admitted as interfering with the universality, and opposing the unqualified assumption, of Dr. Brown, to which we have just alluded.

Guided by these views, Mr. Murray has adopted the general division of medicines under the four heads of *universal stimulants, local stimulants, chemical remedies,* and *mechanical remedies,* which are subdivided in the following manner:

TABLE of CLASSIFICATION.

A. General stimulants.		
	a. Diffusible.	Narcotics.
		Antispasmodics.
	b. Permanent.	Tonics.
		Astringents.
B. Local stimulants.		Emetics.
		Cathartics.
		Emmenagogues.
		Diuretics.
		Diaphoretics.
		Expectorants.
		Sialagogues.
		Errhines.
		Epispastics.
C. Chemical remedies.		Refrigerants.
		Antacids.
		Lithontriptics.
		Escharotics.
D. Mechanical remedies.		Anthelmintics.
		Demulcents.
		Diluents.
		Emollients.

The objections which still lie against this which we have chosen as the most perspicuous and comprehensive arrangement of medicines will be urged, as we proceed to make some observations on their subdivisions, in the order of the above table.

The following, then, may be regarded, with some few exceptions, as an abridgment, or condensation, of the materia medica department of Mr. Murray's treatise. The names of the articles are adopted from the last edition, recently published, of the Parmacopœia collegii regii Medicorum Edinburgensis. In this edition the simples are principally indicated by the Linnæan names. We have added, however, the more customary titles, in order to obviate confusion.

OF NARCOTICS.

Medicines of this class had, previous to the time of Dr. Brown, been almost universally regarded as sedative, or depressing, even in their primary operation. By a bold, and, in some measure, legitimate generalization, our author proved that this kind of agency is, in the greater number of cases, merely of a secondary nature; and that the symptoms of depressed, or, more properly speaking, exhausted power, resulting from their administration, are consequent upon the faculty they possess of exciting, in a prompt and very extraordinary manner, the actions of the system. Thus opium, which is one of the most powerful of the narcotics, Dr. Brown maintained is, in the first instance, invariably stimulant; and the same virtue he attributes to the whole range of narcotic, or, as they were formerly characterized, sedative powers.

Although this conclusion is deduced from principles in the main correct, and in its application has been of abundant service in developing the laws of organic existence, it cannot, as we have above remarked, be admitted as universal, as the fact must be obvious to all who are not biassed by system, that "the sedative effects of narcotics are often disproportioned to their previous exciting operation, allowing even in such cases for its rapidity and little permanence." Murray. This fact then, in some measure, interferes with the correctness of our author's (Mr. Murray's) classification.

Narcotics are employed medicinally with different and opposite intentions. As stimulants they are given in various disorders of debility; in intermittent and continued fever, in gout, hysteria, epilepsy, dropsy, &c. As sedatives they are administered to allay pain and irritation, and are consequently largely administered in spasmodic and painful affections.

Alcohol, ardent spirit; spirit of wine. For the origin and preparation of this consult the article ALCOHOL. The stimulant effect of alcohol is generally known to be very powerful and diffusible; its exciting power is perhaps, in proportion to its sedative quality, greater than any of the other narcotics. Moderate excitement, with proportionate subsequent languor, results from a moderate dose of spirits. In larger quantities it occasions intoxication, delirium, stupor, coma, death.

Alcohol is used externally as a stimulant in muscular pains: it has lately been discovered to be an useful application in the cure of burns. Internally it is seldom employed in medicine without dilution; and then is rather administered as an auxiliary, or solvent of other ingredients.

Ether. Ethers bear some resemblance in their medicinal powers to alcohol: they are more diffusible, and less permanent in their operation. They are employed principally in asthma, hysteria, and other spasmodic affections. Their dose is from half a drachm to one or two drachms. Externally applied, sulphuric ether has been found to relieve spasmodic contraction of the muscles, and is often useful when applied to the temples in headache.

Camphora, laurus camphora (Lin.): habitat, Japan, India. Camphor is a proximate principle of vegetables; it is principally obtained from the laurus camphora of Japan.

In a moderate dose camphor is stimulant; in a larger quantity it invariably diminishes the force of the circulation, and induces sleep.

Camphor has been used as a stimulant in typhus, cynanche maligna, and other affections attended with debi-

lity and irritation; as a sedative in pneuomonia, rheumatism, &c. In mania it has been given as an anodyne. As an antispasmodic it is employed in asthma, St. Vitus's dance, and epilepsy. Its dose is from five to twenty grains. Externally, in combination with oil or liquid opium, camphor has been advantageously used in rheumatism, bruises, and other inflammatory affections.

Papaver somniferum, poppy. Europe, Asia. The concrete juice of the capsule of this plant is opium, which is chiefly imported from Egypt, Turkey, and the East Indies.

The effects of opium, as above stated, are stimulating: it often occasions, when given in somewhat large doses, intoxication, and even actual delirium. If a larger dose be given, the symptoms of diminished action appear without any previous excitement, and are succeeded by delirium, stupor, stertorous breathing, convulsions, and death.

Where opium is given as a stimulus it ought to be administered in small and frequently repeated doses. Where the intention is to mitigate pain or irritation, it ought, on the contrary, to be given in a large dose, and at distant intervals. It is of importance to observe, that where evacuations have been previously procured, or when a state of diaphoresis is present, opium is much more genial and salutary than while the skin is dry, or the bowels torpid.

In continued, as well as intermittent, fevers, opium is given as a stimulus. In the profluviæ of Dr. Cullen, opium is employed to diminish the discharge. In gout it is highly serviceable. In convulsive and spasmodic affections it is often administered to a very great extent, as in the tetanus of warm climates. In lues venerea it is thought to accelerate the action of mercury. It is often given to promote suppuration, and is extremely efficacious in arresting gangrene. In the form of enema opium is often administered in violent affections of the bowels.

Its usual dose is one grain to an adult.

Hyoscyamus niger, indigenous, harba, semen, black henbane. This plant, in its action on the system, bears a considerable resemblance to opium; for which it is often employed as a substitute, where the latter, from idiosyncracy, occasions unpleasant symptoms. It is free from the constipating effects of opium.

Atropa belladonna, indigenous, deadly nightshade. Both the leaves and berries of this plant, and also its root, are narcotic. It is seldom used in medicine.

Aconitum napellus, aconite, monk's-hood, herba. Europe, America.

Aconite has been employed in obstinate chronic rhumatism, in schirrus, &c. Its dose is from one to two grains of the powdered leaves; of the inspissated juice half a grain.

Conium maculatum, cicuta, hemlock, folia, semen, indigenous. This is a powerful narcotic. Like the aconite, it has been used in schirrous and scrophulous affections, as well as in rhumatisms. Dose two or three grains of the powdered leaves; one or two of the inspissated juice.

Digitalis purpurea, foxglove, folia, indigenous. Of all the narcotics, digitalis most speedily and certainly diminishes the actions of the system, especially of the arteries. It acts at the same time as a stimulant on the absorbent system; hence its abundant utility in dropsy. Lately it has been extensively employed in phthisis, and in the early stages of this disorder with remarkable success. Dose one grain of the powdered leaves, and ten drops of the tincture of the Edinburgh pharmacopœia, gradually increased.

Nicotianum tabacum, tobacco, folia. America. This is a powerful narcotic. Its extreme activity prevents it from being much used in medicine.

Lactuca verosa, strong-scented lettuce, folia, indigenous.

From five to ten grains of the inspissated juice, gradually increased, have been given as a narcotic, diuretic, and antispasmodic.

Datura stramonium, thorn-apple, herba, indigenous.

This has been used in mania, epilepsy, and convulsive diseases. Dose from one to three grains of the inspissated juice.

Arnica montana, leopard's-bane, flores, radix. Germany.

The flowers have been used in the dose of five grains in palsy, convulsions, &c. Its root has been employed as a substitute for Peruvian bark.

Rhododendrum chrysanthrum, yellow-flowered rhodadendron, folia, Siberia.

This has been given in chronic rheumatism and gout.

Rhus toxicondendron, poison-oak, folia. N. America. The dried leaves have been used in palsy. Dose half a grain twice or thrice a day.

Strychnos nux vomica, vomica nut. East Indies. It has been employed in mania, hysteria, &c. Dose five grains twice a day.

Prunus lauro-cerasus, cherry-tree laurel, folia, Europe.

This has scarcely been employed in medicine.

OF ANTISPASMODICS.

Antispasmodics form a kind of intermediate class between narcotics and tonics. Spasm sometimes arises from local irritation in states of general irritability, and is sometimes occasioned by pure debility. Both narcotics therefore and tonics are used as antispasmodics; but there are certain substances which in some measure appear to possess a specific antispasmodic power; these we are now to enumerate.

Moschus, musk, moschus moschiferus. South of Asia. Musk is a peculiar substance found in a small sac, situated in the umbilicus in the male of the above animal. Its antispasmodic powers are considerable. Dose from six to twenty grains in the form of bolus: it is useful in much smaller quantities in the convulsions of infants from dentition.

Castoreum, castor, castor fiber. This is a deposition collected in cells near the extremity of the rectum in the beaver. It is much used in hysteria. Dose from ten to twenty grains.

Oleum animale empyreumaticum, empyreumatic animal oil. This is nearly discarded from practice.

Petroleum, a bitumen of a red colour. This was formerly, but is not now, much employed.

Ammonia. This, when employed alone as an antispasmodic, is given in the form of carbonate.

Ferula assafœtida, assafœtida, Persia. This is a concrete juice, obtained by incision from the roots of certain plants. Its dose, as an antispasmodic, is from five to twenty grains.

Sagapenum, gummi-resina, Persia; virtues the same as assafœtida, but inferior in power.

Bubon galbanum, gummi-resina, Africa. Dose ten grains.

Valeriana officinalis, wild valerian: radix, indigenous. This is one of the principal antispasmodics. Dose from one scruple to one drachm, three or four times a day.

Crocus sativus, saffron, indigenous. This substance is composed of the stigmata which crown the pistil of the flower. It has scarcely any virtue.

Melaleucha leucadendron, cajeput oil, India. This is scarcely in use, except as a local application in toothache.

OF TONICS.

This term ought not perhaps to be retained. The agency of tonics is not that of increasing tension or tone, but they are permanent stimulants to the living fibre. Tonics, then, are properly regarded as slow and durable, in opposition to the more diffusible and transient stimuli. They are chosen from the mineral and vegetable kingdom; the former are less speedy and sensible in their action than the latter.

From the mineral Kingdom.

Hydrargyrus, argentum vivum, mercury. *Ferrum*, iron. *Zincum*, zinc. *Cuprum*, copper. *Arsenicum*, arsenic. For the various preparations and medicinal virtues of the above important minerals, consult the articles PHARMACY and MEDICINE.

Barytes, terra ponderosa, heavy earth. This has only been used in medicine combined with muriatic acid. Dr. Crawford introduced the saturated solution into practice as a remedy for scrophula. Dose from five to twenty or more drops.

Calx, lime. This earth exists in nature as a carbonate: like barytes, it has been used as a tonic in combination with muriatic acid.

Acidum nitricum, nitric acid. This acid has been used as a tonic to support the system under a mercurial course. It has likewise been tried, but not with decided and invariable success, as a specific in the cure of lues venerea.

Oxymurias potassæ, oxymuriate of potash. This may be classed as a remedy with the former article. Its dose is, ten grains increased to twenty or twenty-five.

Tonics from the vegetable kingdom.

The tonic faculty in vegetables is intimately united with certain sensible qualities, with bitterness, astringency, and aroma. The aromatic principle is more active, but less permanent in its stimulating operation. The purest bitters independantly possess a tonic power. Astringency, when it exists exclusively, or as the most predominant principle in vegetables, constitutes a distinct class; the remaining tonics may be arranged according as bitterness or aroma is predominant.

Cinchona officinalis, cortex Peruvianus, Peruvian bark, Peru. Three kinds of this bark are in use, the pale, red, and yellow. The last is now principally employed, as it gives out more bitterness and astringency to water, alcohol, and other media. Peruvian bark was first employed in intermittent fever. In this disease it is given in the dose of a scruple or half a drachm every third hour, during the interval of the paroxysm. In continued fever it is principally employed during the latter stages. when debility is urgent. In rheumatism, erysipelas, gangrene, hæmorrhage, and almost all asthenic disorders, it has been administered as a tonic.

Cinchona Caribæa, Caribeean bark, Caribee islands. *Angustura*, Spanish West Indies. These barks have both been used as substitutes for the Peruvian.

Aristolochia serpentaria, Virginian snake-root. This is a stimulating aromatic tonic. It is generally given in the form of tincture.

Dorstenia contrayerva, contrayerva, Peru, West Indies. This is scarcely possessed of any virtue.

Croton eleutheria, cascarilla cortex, N. America. This is another substitute for Peruvian bark. Dose a scruple or half a drachm.

Colomba, radix, Ceylon, a very useful tonic bitter. Dose half a drachm.

Quassia excelsa, lignum, West Indies. This is likewise an excellent tonic. Dose, in substance, from ten to thirty grains.

Quassia simarouba, simarouba, cortex, South America. This has been extolled as a remedy in dysentery, and chronic diarrhœa. Dose a scruple.

Swietenia febrifuga, Swietenia, cortex, East Indies. *Swietenia mahagani*, mahogany. Two other proposed substitutes for the Peruvian bark.

Gentiana lutea, gentian, Switzerland, Germany. This is a common and useful remedy in dyspepsia; its virtues are extracted both by water and spirit. Dose in substance half a drachm.

Anthemis nobilis, chamomile, flores, indigenous; a powerful and well-known bitter. N. B. The following plants are now not used in medicine: *artemisia absinthium*, wormwood; *chironia centaurum*, centaury; *marrubium vulgare*, horehound; *menyanthes trifoliata*, trefoil; *centaura benedicta*, blessed thistle.

AROMATICS.

Citrus aurantium, orange, cortex flavus. The rind of the orange is principally employed as an addition to combinations of bitters used in dyspepsia. It is given in the form of tincture, conserve, and syrup.

Citrus medica, lemon, cortex fructus, Asia; similar in flavour and virtue, but rather less bitter than the orange.

Laurus cinnamomum, cinnamon, cortex, Ceylon. This is the most grateful of the aromatics.

Laurus cassia, cassia, cortex, E. Indies. This nearly resembles the cinnamon in appearance, taste, and virtue. It is therefore used with the same intention as this last. Its flavour, however, is less grateful.

Canella alba, cortex, West Indies. This is a moderately strong aromatic: it is not much used except in combination with other substances in the form of tincture.

Acorus calamus, sweet-scented flag, radix, indigenous. This is scarcely at all employed in medicine.

Ammomum zingiber, ginger, radix, East Indies. The dose of ginger is about ten grains.

Kæmpferia rotunda, zedoaria, radix, East Indies. This is seldom employed in medicine.

Santalum album, yellow sanders, lignum, E. Indies. This wood is now nearly banished from practice.

Pterocarpus santalinus, santalum rubrum, red sanders, lignum, India. This, although slightly aromatic, is at present merely used in pharmacy as a colouring ingredient.

Myristica moschata, India. Under the officinal name myristica, both nutmeg and mace are included: the former is the seed, or kernel of the fruit; the latter its capsule. Nutmeg is given as an aromatic in doses of from five to fifteen grains. In larger doses it is narcotic. Mace is employed for the same purposes as nutmeg.

Carophyllus aromaticus, clove, flores, India. Cloves are the unexpanded flowers of the plant. Dose from five to ten grains.

Capsicum annuum, capsicum, Guinea pepper, fructus, E. and W. Indies. This fruit is a very powerful stimulant. It is not in much use as a medicine. Dose from five to ten grains.

Piper nigrum, black pepper, fruit, India. Black pepper is the unripe fruit of the plant. White pepper is the ripe berry of the same vegetable, freed from its outer covering. It is milder than the black. Dose ten or fifteen grains.

Piper longum, long pepper. This is the berry of the plant, gathered before it is fully ripened. It is similar to the black pepper in its qualities.

Piper Cubeba, cubebs, the dried fruit of the tree. It has similar virtues to the other peppers.

Myrtus pimenta, Jamaica pepper, baccæ, W. Indies. This is usually called pimento; it is used in medicine principally on account of its flavour.

Amomum repens, lesser cardamom, semen. Cardamoms form an ingredient in many of the bitter tinctures.

Carum carui, caraway, semen, indigenous. These are in common use, in culinary as well as medicinal preparations.

Coriandum sativum, coriander, semen. South of Europe. These are used with the same intention as caraway.

Pimpinella anisum, anise, semen, Egypt. Anise is used chiefly in the flatulence of children. The four following seeds have similar virtues to the anise and caraway: *Anethum fœniculum*, sweet fennel, semen, indigenous. *Anethum graveolens*, dill, semen, Spain and Portugal. *Cumimum cyminum*, cumin, semen, South of Europe.

Angelica archangelica, garden angelica, semen, folia, radix. North of Europe.

Mentha piperita, peppermint, herba, indigenous. *Mentha viridis*, spear mint, herba, indigenous. *Mentha pulegium*, penny-royal, herba, indigenous. Of these three mints the first is the most pungent and carminative.

Hyssopus officinalis, hyssop, herba, Asia, South and East of Europe. This plant is nearly similar in virtues to the mints just enumerated.

OF ASTRINGENTS.

Astringents are those substances that restrain morbid evacuations. Their mode of operation has been erroneously supposed similar to that by which dead animal matter is constringed and condensed. Increased evacuations do not depend merely upon mechanical laxity of the solids; the process, therefore, by which they are arrested, cannot entirely be ascribed to chemical principles; although in some cases medicines which are employed to arrest profuse discharges, confessedly possess a power of constringing dead animal fibre. This faculty in vegetables is denominated astringency, and results from the union of gallic acid and tanning principle combined; the former, when separated, is distinguished by its property of striking a deep-black colour with the salts of iron; the other by its great attraction to animal gelatin. Vegetable astringents then may be considered as moderate permanent stimuli, modified in their action, even on living matter, by the principle above alluded to. Inordinate evacuations are, however, often restrained by mineral as well as vegetable substances, and in this case the former deserve to be arranged in the class of astringents, according to the definition above given of these powers. Dr. Darwin refers astringency to the promotion of absorption. Many agents, however, which have the greatest efficacy in exciting the absorbent vessels, are not capable of stopping hæmorrhages, or other morbid discharges.

Vegetable Astringents.

Quercus robur, oak, cortex, indigenous. This has been employed in hæmorrhage, diarrhœa, and intermittent fever. Its dose in powder is from fifteen to thirty grains.

Quercus cerris, galls, south of Europe. These are tubercles found on the branch of the tree which produces them. They are employed in medicine for the same purposes, and are used under the same forms, as oak-bark.

Tormentilla erecta, tormentil, radix, indigenous. This has been used in diarrhœa in decoction. Its dose in substance, is from half a drachm to a drachm.

Polygonum bistorta, bistort, radix, indigenous. This is a strong astringent. Dose a scruple to a drachm.

Anchusa tinctoria, alkanet, radix, South of Europe. This is at present merely employed as a colouring matter.

Hæmatoxylon Campechianum, logwood. It is used as an astringent under the form of decoction, or watery extract.

Rosa gallica, red rose, South of Europe. The principle use of this astringent is in the form of gargle.

Arbutus uva ursi, bear's wortle-berry, folia, Europe, America. This has been principally given in disorders of the urinary organs. Recently it has been proposed in phthisis pulmonalis.

Mimosa catechu, catechu, or Japan earth, East Indies. This is a powerful and useful astringent in diarrhœa. Its dose is from fifteen to thirty grains. *Kino* is employed with the same intention as catechu. Its dose is from twenty to thirty grains.

Pterocarpus draco, dragon's blood, resina, South America. This is scarcely employed in medicine.

Lacca, lac, ficus indica, resina, East Indies. Lac is very little employed as a medicinal.

Pistacea lentiscus, mastiche, resina, South of Europe. This is likewise discarded from practice.

Mineral Astringents.

The chief of these are the mineral acids, especially the sulphuric, and the compounds this acid affords with metals and earths.

Acidum sulphuricum, vitriolic acid. This is used in

hæmoptysis, menorrhagia, diabetes, hectic, &c. It is given in general in the form of diluted acid. Dose from en to thirty drops.

Argilla, argil, argillaceous earth with oxyd of iron, forming the boles of which the chief is the armenian bole, were formerly employed in, but are now rejected from, practice as nearly inert.

Supersulphas argillæ et potassæ, alum, is given in hæmorrhage, and serous evacuations. Its dose is from five to fifteen grains.

Calx, lime; calx viva, quicklime. Lime has been employed as an astringent in the form of lime-water; it is now not much used.

Carbonas calcis, carbonate of lime. The carbonates of ime are chalk (creta alba), crab's-claws (chelæ cancrorum), oyster-shells (testæ astreorum); they are rather antacids than strictly astringents.

Plumbum, lead. This, in the form of oxyd, or salts, is evidently and powerfully astringent. Its preparations that are employed are the white oxyd (cerusa, white lead), and the acetate (acetis plumbi, sugar of lead).

Zincum, zinc. The sulphate of zinc (sulphas zinci), and the acetate (acetis zinci), are both powerful astringents. The former is in principal use. It is given sometimes in dysentery, in the dose of two or three grains twice a day. In injections and collyria, it is employed in the proportion of two or three grains to an ounce of water.

Ferrum, iron. The sulphate is the most astringent preparation of iron: it is, however, oftener used as a tonic than astringent.

Cuprum, copper. The saline preparations of this metal are considerably astringent. The sulphas cupri is the most powerful. It has been employed externally as a styptic. The acetite of copper (verdigris) is used as a collyrium from its astringent styptic property.

OF EMETICS.

Emetics are very properly defined by Mr. Murray, "Substances capable of exciting vomiting, independant of any effect arising from the mere quantity of matter introduced into the stomach, or of any nauseous taste or flavour." The phenomenon of vomiting, as to its remote cause, is of a difficult explanation. It cannot be owing simply to debilitated, and consequently inverted action of the stomach from previous excitement, as a greater quantity of stimulus may be thrown into this organ without being succeeded by an inversion of its peristaltic motion. Dr. Darwin attributes the effect to a suspension of the exciting power of pleasurable sensation, in consequence of which the fibres of the stomach are arrested for a time, and at length, from the undue accumulation of irritability, their action becomes inverted. The sensation of nausea does not, however, invariably precede the act of vomiting; and even allowing this feeling to be a necessary prelude, the cause of the sensation itself is left unexplained by the sensorial theory of Dr. Darwin.

The utility of emetics under some circumstances of the system is very extensive. Their salutary effects are not solely referable to the discharge which they occasion; but they also produce other changes on the living body, both general and partial, which will be noticed in the article Medicine.

Emetics are derived from the vegetable and mineral kingdoms.

Emetics from the vegetable Kingdom.

Ipecacuanha, ipecacuan, radix, South America.

This root is the one in most general use as an emetic: it is both mild and certain in its operation. It is given in a dose from fifteen to thirty grains. Ipecacuan is employed in conjunction with opium, as a diaphoretic. In this case its dose is from three or four to ten grains.

Scilla maritima, squill, radix, South of Europe. This bulbous root of a plant growing on the sandy shores of Spain and Italy, is not at present in much use as an emetic: it is principally employed as an expectorant and diuretic.

Sinapis alba, mustard, semen, indigenous. This perhaps might have been classed among the aromatics. When employed as an emetic, its administration has been principally confined to paralytic affections. It is given in the dose of a tea-spoonful mixed with water.

Asarum Europæum, asarabacca, folia, indigenous. The introduction of ipecacuan into practice, has almost superseded the use of this powerful drug. Dose twenty grains of the dried leaves; of the dried root ten grains.

Nicotiana tabacum, tobacco.

This is a violent emetic, as well as narcotic. It is scarce ever employed in practice.

From the mineral Kingdom.

Antimonium, stibium, antimony.

Than antimony, scarcely any mineral is in more general use: it is, however, seldom used but in a state of combination with oxygen or acid. Its preparations, doses, and virtues, will be treated of under the articles Pharmacy and Medicine.

Sulphas zinc, sulphate of zinc.

This salt is sudden in its operation: it is in principal use in cases of poisons having been received into the stomach. Its dose is from ten grains to a scruple.

Sulphas cupri, sulphate of copper.

Neither this nor the acetite of copper is in much use; they are violent in their operation, and in no respect preferable to milder emetics.

OF CATHARTICS.

A discharge of the intestinal contents appears to be occasioned by medicines upon a twofold principle. Cathartics either immediately excite the fibres of the intestines, thus accelerating their peristaltic motion, and consequent fæcal evacuations, or they produce this effect more immediately by stimulating the exhalant and secerning vessels; whose fluids (the bile, pancreatic juice, and intestinal mucus) act as solvents to, and promote the discharge of, the fæces. These latter are milder in their operation than the former: they are classed by Darwin among the secernentia. There are, however, many drugs which act at the same time in each of the above modes.

Cathartics, still more than emetics, are extensively employed in medicine, as capable of operating important changes throughout the system. Their use has recently been brought more systematically into notice.

Upon the grounds just stated, cathartics may with some propriety be divided into purgative and laxative.

Purgatives.

Cassia senna, senna, folia, Egypt, Arabia. This is frequently employed: it is given in the form of infusion. Dose a drachm or more.

Rheum palmatum, rhubarb, radix, Tartary.

The best rhubarb is imported from Turkey. The China rhubarb has less of the aromatic flavour. British rhubarb is much inferior to either. The dose of rhubarb, as a cathartic, is from fifteen grains to two scruples. It is given with advantage in diarrhœa and dysentery, as it contains an astringent principle. In small doses it is stomachic and tonic.

Convolvulus jalapa, jalap, radix, Mexico. This is often administered both alone and more especially with calomel (submurias hydrargyri). Its dose is from fifteen grains to two scruples.

Helleborus niger, black hellebore, radix, Austria, Italy.

This, in a dose from ten to twenty grains, is a violent cathartic. It is seldom employed in modern practice. Dr. Mead attributed a powerful emmenagogue property to it, which however has scarcely been realized by others. The ancient physicians gave it freely in maniacal disorders.

Bryonia alba, bryony, radix, indigenous. This root is not much used. Dose from twenty to thirty grains. It is slightly diuretic.

Cucumis colocynthis, colocynth, fructus, pulpa, Syria.

A drastic purgative in a dose from three to six grains. It is seldom given by itself. It has been chiefly had recourse to in obstinate constipation.

Momordica elaterium, wild cucumber, fructus, south of Europe.

This is the most violent of all purgatives. Its dose is half a grain to two grains.

Rhamnus catharticus, buckthorn, baccarum succus, indigenous. This is seldom used.

Aloe perfoliata, socotrine, Barbadoes, or hepatic and cabbaline aloes; succus spissatus, Africa, Asia, America.

The socotrine aloes is the purest. The Barbadoes and hepatic rank next. The cabbaline is the most impure, and is the weakest. Dose from fifteen grains to a scruple. Its action is principally upon the larger intestines, and on account of the vicinity to, and sympathy of these with, the uterus, it is often useful in amenorrhœa.

Convolvulus scammonia, scammony, gummi-resina, Syria.

This is a very drastic cathartic. Dose from five to ten grains.

Gambogia gutta, gamboge, gummi-resina. East Indies.

Another violent cathartic. Dose from one to four or five grains. In conjunction with the last and following article gamboge is often administered in dropsy.

Submurias hydrargyri, mild muriate or mercury, calomel.

Dose from five to eight or ten grains.

Laxatives.

Manna, manna, fraxinus ornus, succus concretus, South of Europe.

This is a mild and pleasant laxative. It is frequently given to children in conjunction with senna. Dose to an adult from one to two ounces.

Cassia fistula, purging cassia, or cassia in the pod; pulpa fructus, Egypt, East and West Indies.

Dose from four to six drachms.

Tamarindus Indica, tamarind, fructus conditus, E. and W. Indies, America, Arabia.

The tamarinds of the shops is the pulp of the tree mixed with seeds and small fibres, with a quantity of coarse sugar.

It may be taken to the extent of two ounces, or more.

Ricinus communis, palma Christi, oleum, semen, W. Indies.

The oil from the nuts of palma Christi is the castor oil of the shops. This is a mild and very useful purgative.

Sulphur, a simple inflammable substance, and *magnesia*, either pure or carbonated, are all the laxitives that are afforded by the mineral kingdom. The operation of either is exceedingly mild.

For the different neutral salts that are employed as purgatives in medicine, see PHARMACY.

The purgatives that are administered only in the form of enema, are the

Murias sodæ, common salt. An ounce of this dissolved in a pint of tepid water with an ounce of expressed oil, forms the common domestic enema.

Terebinthina veneta, turpentine, pinus larix, gummiresina. This is sometimes employed as an enema triturated with the yolk of an egg. Dr. Cullen recommends this as a very certain cathartic. It is indicated in obstinate costiveness.

Nicotiana. The introduction per-ano of tobacco smoke has sometimes been effectual in procuring alvine evacuation, after other cathartics have failed. The infusion of from one to two drachms in a pint of water is a more convenient mode of administering this medicine. Much caution is requisite in either case to obviate its depressing effects.

OF EMMENAGOGUES.

These are medicines which promote the menstrual discharge. Obstruction or retention of the menses, unless consequent upon defective conformation, or uterine impregnation, is usually owing to weakness or want of due excitation in the vessels of the uterus.

This debility is best overcome by general stimulating and tonic agents, which thus acting, become emmenagogues; sometimes, however, it is necessary more immediately and directly to excite the parts in the vicinity of the uterus, by such purgatives whose action is principally directed to the inferior portion of the intestinal canal. In this case these cathartics prove emmenagogues, but not, as was formerly conjectured, by virtue of any specific power.

Emmenagogues from the class of tonics.

Ferrum, the carbonate of iron, rubigo ferri præparata; is given in a dose of ten or fifteen grains in amenorrhœa; the sulphate of iron in three or four grains. This last is the ferrum vitriolatum of the London pharmacopœa.

Hydrargyrus, the mild muriate of mercury, as already noticed.

Cinchona. This is frequently given in amenorrhœa, in conjunction with some of the preparations of iron.

From the class of antispasmodics.

Castoreum. This is a medicine of very trifling efficacy when used as an emmenagogue. Dose from ten to twenty grains.

Ferula assafœtida, and the other fœtid gums, (galba-

num, sagapenum, and ammoniacum) are employed sometimes as emmenagogues. Dose from ten grains to fifteen.

From the class of cathartics.

Aloes. This substance is generally connected with others when given to promote the menses, as in the pilula aloes cum myrrha, &c.

Helleborus niger. This is not at present in much repute. Dose of the extract from three to ten grains.

Sinapis alba, semen, mustard-seed in the dose of about half an ounce is sometimes taken as an emmenagogue.

Rosmarinus officinalis, rosemary, summitales florentis. This is now nearly banished from practice.

Rubia tinctorum, madder, radix, south of Europe. Dose from a scruple to half a drachm. Its virtues are not much confided in by modern physicians.

Rutea graveolens, ruta, rue, herba, south of Europe. The herb in the form of infusion, and likewise its essential oil, are the preparations of rue that are given. It is perhaps of inferior efficacy.

Juniperus sabina, savin, folia, south of Europe. Savin is not much used internally, although supposed by some to be a powerful emmenagogue.

OF DIURETICS.

Diuretics are those medicines which augment the urinary discharge. This effect is either produced by a direct stimulus communicated to the kidneys, by a sympathetic excitement of these organs from a previous action excited in the stomach, or lastly, by the promotion of absorption, by which more than their usual quantity is directed to the secretory vessels of the urine. The saline diaphoretics seem principally to exert their agency in the first of these ways. Squill and others appear to produce a primary action of the stomach, and digitalis from its extraordinary power over the absorbent system is an example of the last-mentioned mode of procuring diuresis.

Saline diuretics.

Supertartris potassæ, cream of tartar. Dose four or six drachms twice a day in a considerable quantity of water. This has been much employed in dropsy.

Nitras potassæ nitre. Dose from five to twenty grains. Nitre was formerly much used in gonorrhœ, in order to abate the ardor urinæ.

Murias ammoniæ, crude sal ammoniac. This is not much employed. Dose from eight grains to a scruple.

Acetis potassæ, sal diureticus. This has now likewise fallen into disuse.

Potassa, kali. The dose of carbonated kali is from twenty to thirty grains.

Vegetable diuretics.

Scilla maritima. Dose as a diuretic from one to three or four grains.

Digitalis purpurea. Dose from one grain to two or more, of the powdered leaves: from ten to thirty drops of the saturated tincture. The dose requires to be regulated and increased with much caution.

Nicotiana tabacum. An ounce of the dried leaves infused in a pint of water, has been given as a diuretic in the dose of from sixty to a hundred drops.

Solanum dulcamara, woody nightshade, bitter, sweet, indigenous. This is scarcely ever prescribed.

Lactuca verosa. Dose from ten grains to three drachms. It is not much used.

Colchium autumnale, meadow saffron, indigenous. This has not been in much use in this country. It was first prescribed in dropsy by Stork of Vienna.

Gratiola officinalis, hedge hyssop, south of Europe. The leaves of this plant have likewise been given in dropsy, but they have not come into general use.

Spartium scoparium, broom, summitales, indigenous.

The broom tops infused in water have proved advantageous in dropsy.

Juniperus communis, juniper, baccæ, indigenous. Juniper berries given in infusion have a pretty considerable diuretic power.

Copaifera officinalis, copaiva balsam, South America. Dose from twenty to thirty drops twice a day. It is principally employed in gleet.

Pinus larix, Venice turpentine, balsamum. Dose from five to twelve drops of the essential oil. This has likewise been given in gleet, and in ichias.

Pistachia terebinthinus, Cyprus turpentine. This is more fragrant than the balsam from the pinus; as is likewise Strasburgh turpentine, the produce of the pinus picea. The common turpentine (pinus sylvestris balsam) is on the other hand the most offensive.

Diuretics from the animal Kingdom.

Meloe vesicatorius, cantharides, Spanish fly. This is an insect collected from the leaves of plants growing in the South of Europe. It has principally been given internally for gleet and retention of urine. Dose one grain gradually increased.

OF DIAPHORETICS.

If the natural and constant exhalation from the skin be condensed on the surface from its augmented discharge, it constitutes sweat. This effect when produced only to a certain extent, is called diaphoresis. Diaphoretic and sudorific powers differ then only in degree. Diaphoretics are classed by Darwin under the head of secernentia. They necessarily operate by directly or indirectly exciting the cutaneous exhalants. The saline and cooling diaphoretics appear to act in the latter, the heating medicinals which are given to procure sweat in the former manner. Diaphoretics with respect to their influence on the system, are often abundantly powerful and salutary.

Ammonia. All saline preparations are more or less diaphoretic under proper regulation. The ammoniacal salts have been imagined to be so in a greater degree than others. See PHARMACY.

Hydrargyrus. The mild muriate (calomel) in conjunction with opium in very small doses, is sometimes usefully employed as a diaphoretic.

Antimonium. All the preparations of antimony may be made to prove sudorific.

Ipecacuanha. In a dose of two or three grains with or without an opiate.

Opium. This when employed as a diaphoretic is generally combined with one or other of the three former medicines.

Camphor likewise must be united with mercury, antimony, or opium, when it is intended as a diaphoretic.

Guaiacum officinale, guaiac lignum, et gummi-resina, South America, and the West Indies. Guaiac wood is

given in the form of decoction, a quart of which is given in the course of the day. The gum-resin is commonly administered in spirit of ammonia, from which it derives a considerable part of its virtues. Dose from one drachm to two of the tincture.

Daphne mezereum, mezereon, cortex radicis, indigenous. This is a stimulating diaphoretic: it is generally given in lues venerea, with sarsaparilla, and guaiac, forming the Lisbon diet-drink.

Smilax sarsaparilla, radix, South America. This has scarcely any power exclusively employed.

Lauras sassafras, sassafras, lignum, America. This is slightly stimulant and diaphoretic. It is probably less efficacious than has generally been imagined.

Cachlearia armoracia, horse-radish, radix, indigenous. This is a stimulant capable of promoting perspiration. About a drachm of the root cut in small pieces and swallowed whole, has been recommended in paralysis, rhumatism, asthma, and dropsy.

Salvia officinalis, sage, folia, south of Europe. Its aqueous infusion drunk warm is slightly stimulant and diaphoretic.

EXPECTORANTS

Are those medicines which facilitate the rejection of mucus or other fluids from the lungs. This object is accomplished by increasing pulmonary exhalation where deficient, or diminishing it when too copious. In the one instance expectorants are secernent, in the other absorbent powers: their operation, like that of emetics, is in both cases either direct or indirect.

Antimonium. The most common preparation of antimony for an expectorant is the emetic tartar of the shops. This is given in pneumonia, catarrh, hooping cough, and asthma, in the dose of one eighth of a grain. It is generally combined with opiates in mucilaginous mixtures, and in this way is more efficacious.

Ipecacuanha. It is given with the same intention in a dose of two or three grains.

Digitalis, in the dose of half a grain, has been used as an expectorant, as likewise

Nicotiana, in the dose of one, two, or three grains.

Scilla. This is one of the most effectual of the expectorantia. Dose one grain of the dried root.

Allium sativum, garlic, radix, south of Europe. Garlic is given in humoral asthma, dropsy, &c. in the dose of half a drachm or two scruples.

Polygala senega, seneka, radix, North America. Dose from ten grains to a scruple. It is chiefly employed in the secondary stage of pneumonia.

Ammoniacum, ammoniac, East Indies, gummi-resina. Dose from ten to thirty grains. This is frequently used as an expectorant.

Assafœtida. Dose from ten to twenty grains.

Myrrha, myrrh, gummi-resina, Abyssinia and Arabia. Dose from ten to twenty grains.

N. B. The plants producing the above two gum-resins are unknown.

Styrax benzoin, benzoir or Benjamin, balsamum, East Indies. Dose ten or fifteen grains. It is perhaps possessed of little power.

Styrax officinale, storax, bals. south of Europe, Asia. Storax is like benzoin in its virtues.

Toluifera balsamum, balsam of tolu, South America. The powers of this balsam are very inconsiderable.

Myroxolon peruiferum, Peruvian balsam, South America. Dose in asthma, leucorrhœa, &c. from five to fifteen grains.

Amyris gileadensis, balm of Gilead, Arabia. The qualities of this nearly resemble the balsam of tolu.

OF SIALAGOGUES.

These are substances which increase the secretion of saliva. This is in general effected by mastication of acrid substances, but in some few instances is occasioned by medicines taken into the stomach. Mercury, perhaps, is the only medicine which uniformly displays a sialagogue power.

Hydrarrgyrus. All the preparations of mercury have more or less influence over the salivary glands.

Anthemis pyretrum, pellitory of Spain, radix, south of Europe. This is sometimes chewed in order to relieve the tooth-ache.

Arum macnlatum, wake-Robin, radix, indigenous. This resembles pellitory, and may be employed with the same intention.

Ginger, mezereum, and tobacco especially, are sometimes used as sialagogues.

ERRHINES

Are medicines which occasion a more than ordinary secretion from the mucous membrane of the nostrils. They all operate by direct application.

Iris florentina, Florentine orris, radix, south of Europe. This is a mild sternutatory and forms one of the ingredients of some cephalic snuffs.

Æsculus hippocastinum, horse chesnut, semen. This acts as a moderate sternutatory.

Origanum majorana, sweet marjorum, herba, south of Europe. This has a slight errhine power.

Lavandula spica, lavender, spicæ florentes, south of Europe. The dried leaves in powder.

Nicotiana, tobacco. The powder of the dried leaves is the basis of snuffs.

Asarum Europœum, asarabaca, folia, indigenous. The leaves of this plant in powder form the basis of officinal sternutatory powders.

Veratram album, white hellebore, radix, south of Europe. This is a very violent errhine.

Euphorbia officinalis, gummi-resina, Africa. This is the most powerful of all the errhines. It is seldom or never employed.

Subsulphus hydrargyri. This preparation of mercury has been recommended to be snuffed up the nostrils in some kinds of chronic ophthalmia.

EPISPASTICS AND RUBEFACIANTS.

Epispastics are those substances which applied to the skin produce either serous or purulent discharge through the medium of inflammation. Rubefaciants occasion inflamation, but not so violent as to be followed by such discharges.

Meloe vesicatorius, cantharis, Spanish fly. This is the principal substance employed for blistering. After a blister has been raised the discharge is often converted from serum into pus by the continued application of any

stimulating acid ointment. This practice is often pursued in asthma, paralysis, &c.

Cantharides in the form of tincture may be employed simply as a rubefaciant.

Ammonia with oil, forms a liniment for this purpose.

Pinus albus, Burgundy pitch, resina. This is used in the form of plaster, in chronic affections of the lungs and chest.

Sinapis, mustard. The flour of mustard-seed mixed with crumbs of bread, and made into a paste with vinegar, forms a sinapism, a powerful rubefacient. It is applied to the soles of the feet in cases of pressing debility, as in the last stages typhoid fever, and in comatose affections.

Allium, garlick. The bruised root of this plant is used for similar purposes with the mustard sinapism.

OF REFRIGERANTS.

Mr. Murray considers those medicines which directly lower the temperature of the body, to be principally chemical in their operation. They are acids, or substances containing a superabundant proportion of oxygen, which being received into the stomach, occasions a less demand for this principle (oxygen) by the lungs, and consequently a less generation or evolution of heat. This doctrine, however, does not appear satisfactory. See PHYSIOLOGY, Sections *Digestion* and *Respiration;* and MEDICINE, Section *Fever*, &c.

Of refringerants, the vegetable acids are the most efficacious.

Citrus aurantium, orange, succus fructus. The acidity of China orange is connected with sweetness, of the orange from Serville with bitterness. The former is used as a refrigerant in fever.

Citrus medica, lemon, succus fructus. The juice of the lemon is composed of citric acid, and saccharine and mucilaginous matter. It is the most powerful and agreeable of the refrigerants. With carbonate of potass, (kali prep.) it forms the saline draught, the virtues of which are perhaps owing to the carbonic acid that is evolved by the mixture of the acid and alkali.

Tamarindus indica. Tamarind is a very pleasant refrigerant: a solution of it in water constitutes a pleasant beverage in fever.

Acidum acetosum, vinegar. The use of this in medicine is principally as a substitute for the lemon-juice.

Supertartris potassæ, cream of tartar.

Nitras potassæ. This is given as a refrigerant, in a dose of from five grains to a scruple.

ANTACIDS.

These perhaps are more strictly chemical in their primary operation than the last class of medicines. They immediately neutralise the prevailing morbid acidity of the stomach.

Alkalies. Pure potass in solution is employed to correct acidity, in doses of fifteen drops in water. The carbonates of potass and soda are, however, in more general use for this purpose.

Aqua ammoniæ is given likewise with this intent. Dose from twenty to forty drops.

Aqua calcis. Lime-water is also used to correct acidity; six or eight ounces being taken occasionally.

Carbonas calcis. Of this there are two varieties, creta alba, (prepared chalk) and chelæ cancrorum (crab's claws). These, especially the former, are principally used in the diarrhœa of infants.

Magnesia (carbonas magnesiæ). This is in some cases preferable to chalk as an antacid, as the neutral compound formed by its union with the acid of the stomach proves slightly purgative.

OF LITHONTRIPTICS,

Medicines supposed to have a power of dissolving stone in the bladder. Calculus is principally formed by a peculiar acid, called the lithic, or uric, with which alkalies unite out of the body, and thus become solvents of the stone. These medicines, however, cannot in any way be conveyed to the urinary organs in sufficient quantity to effect this purpose, without material injury to the parts and the general system. It has indeed been ascertained, from experiment, that by the exhibition of alkaline substances, for a length of time, the constitutional disposition to secrete fresh caculus is in a great measure obviated. These substances then are rather preventives than curatives of calculary disorders. That they do not, when taken into the stomach, operate as solvents, is sufficiently evident, from the circumstance of their being more useful when administered saturated with carbonic acid; for these alkaline carbonates do not exert any action on the urinary calculi out of the body, as the lithic acid of the concretion is not of sufficient attractive power to disengage the carbonic acid from its union with the salt. The only power then that is possessed by the medicines termed lithontriptics, is that of neutralizing acidity in the first pasages, and thus preventing the deposition of lithic acid in the urinary organs.

Potassa, potass. The dose of the solution of pure potass is 15 or 20 drops gradually increased. The form in which it is generally employed as a lithontriptic, is in the supersaturated solution. Dose, one or two pounds daily.

Soda. This is likewise used in the form of saturated solution, under the name of soda water. Dose, one or two pounds.

Sapo albus. Soap is a combination of expressed oil with potass or soda. Dose, one or two ounces in the course of the day.

Calx. Lime-water is sometimes employed as a lithontriptic.

ESCHAROTICS

Are substances which destroy the texture of both living and dead animal matter. They are employed to consume excrescences, or to open ulcer. Their action on the living system is principally, but not entirely, chemical.

The mineral acids have been employed as escharotics, but are not convenient, in consequence of their fluidity.

Potassa, in its solid state, is a powerful escharotic: mixed with lime it is somewhat milder.

Nitras argenti. Lunar caustic. This is in common use.

Murias antimonii. A powerful caustic, but inconvenient from its being in a fluid form.

Sulphas cupri is often employed.

Acetis cupri. (Verdigris.) This is milder than the sulphate.

Murias hydrargyri. Principally used in the venereal ulcers.

Subnitras hydrargyri. Employed with the same intention as the muriate.

Oxydum arsenici albi. A solution of white arsenic is sometimes made use of as an external application to cancer.

Juniperus sabina. Savine is principally applied in the form of ointment to obstinate ulcers. It is used in powder to consume warts.

ANTHELMINTICS

Are those medicines employed to expel worms from the intestinal canal. Their operation is supposed to be different. Some acting mechanically by the sharpness or roughness of their particles, as filings of tin, cowhage, &c. Others prove noxious to these animals from their poisonous and narcotic properties, or expel them by simply evacuating the bowels, as pink root, worm seed, gamboge, calomel, &c.

Dolichos pruriens, cowhage, East and West Indies. This substance is the down growing on the pods of the plant. The action of this medicine may perhaps be principally mechanical.

Ferrum, iron. The filings and rust.

Stannum, tin. This is used in the form of powder. Tin may perhaps operate by a mechanical power. Dose, one or two drachms.

Olea Europœa, olive oil, oleum expressum, South of Europe. Dose half a pound.

Artemisia santonica, worm seed, Persia. Dose half a drachm.

Spigelia marilandica, Indian pink, radix, North America. Dose half a drachm.

Polypodium filix mas, male fern, radix, indigenous. Dose two or three drachms.

Tanacetum vulgare, tansy, folia et flores, indigenous. Dose from a scruple to a drachm.

Geoffula inermis, cabbage bark-tree, cortex, Jamaica. Dose thirty grains.

Gambogia. Dose from five to twenty grains.

Submurias hydrargyri. Calomel is perhaps the most efficacious of all the anthelmintics. Dose ten or twelve grains to an adult.

DEMULCENTS

Are substances employed in medicine to shield from acrimony; they can only act on the parts to which they are directly applied. From some circumstances, however, attending their internal administration, it is supposed that they are capable of being absorbed and again separated by particular secretory organs. This supposition does not appear to be entirely satisfactory.

Mimosa nilotica, gum arabic, Africa. This is used to allay the irritation of the fauces in catarrh. It is likewise given in tenesmus, strangury, &c.

Astragalus tragacantha. tragacanth, South of Europe, Asia. This has virtues similar to gum arabic. It is more viscid.

Linum usitatissimum, flax, semen, indigenous. This is sometimes used in gonorrhœa, and catarrh.

Althæa officinalis, marsh mallow, radix, indigenous.

Malva sylvestris, common mallow, folia, indigenous.

Glycyrrhiza glabra, liquorice, radix, South of Europe. These three last are all pleasant demulcents.

Cycas circinalis, sago, East Indies. This is a fæcula from the pith of the plant; it is often given in dysentery, &c. as demulcent and at the same time nutritive.

Orchis mascula, salop, indigenous. Similar in virtue to sago.

Maranta arundinacea, South America. Arrow-root is demulcent, and slightly nutritive.

Tryticum hybernum, wheat, amylum. Starch is useful as an enema with opium in dysentery, &c.

Cornu cervi rasura, hartshorn shavings.

Icthyocolla, isinglass is obtained from the skin of the fish. Isinglass is a demulcent in frequent use.

Olea olivæ. The expressed oil principally used as a demulcent is obtained from the fruit of the olive.

Amygdalus communis, almond oil. Ol. express. South of Europe.

Sævum ceti. Spermaceti is obtained from the head of a certain species of whale. Like the almond oil, it is given as a demulcent in catarrh, &c.

Cera, wax. This is collected from the antheræ of vegetables by bees. This is particularly employed in the composition of ointments and plasters.

Of diluents and emollients the two remaining classes scarcely any thing remains to be said. Water, strictly speaking, is the only diluent, and emollients are chiefly formed of heat combined with moisture, as in formations and cataplasms; or of unctuous substances, as lard (axungia porcina) and the varieties of expressed oils.

MATHEMATICAL INSTRUMENTS. See INSTRUMENTS.

MATHEMATICS, from μαθησις, originally signified any discipline or learning; but at present denotes that science which teaches or contemplates whatever is capable of being numbered or measured, in so far as computable or measurable, and accordingly is subdivided into arithmetic, which has number for its object, and geometry, which treats of magnitude. See ARITHMETIC, and GEOMETRY.

Mathematics are commonly distinguished into pure and speculative, which consider quantity abstractedly; and mixed, which treat of magnitude as subsisting in material bodies, and consequently are interwoven every where with physical considerations.

Mixed mathematics are very comprehensive; since to them may be referred astronomy, optics, geography, hydrostatics, mechanics, fortification, navigation, &c. See ASTRONOMY, OPTICS, &c.

Pure mathematics have one peculiar advantage, that they occasion no disputes among wrangling disputants, as in other branches of knowledge; and the reason is, because the definitions of the terms are premised, and every body that reads a proposition has the same idea of every part of it. Hence it is easy to put an end to all mathematical controversies, by showing either that our adversary has not stuck to his definitions, or has not laid down true premises; or else that he has drawn false conclusions from true principles; and in case we are able to do neither of these, we must acknowledge the truth of what he has proved.

It is true, that in mixed mathematics, where we reason mathematically upon physical subjects, we cannot give such just definitions as the geometricians; we must therefore rest content with descriptions, and they will be of the same use as definitions, provided we are consis-

MAX

principles, which appear essentially different from each other, and which have never yet been brought to a more simple form. Thus the matter of fire, or light, appears totally different from that of all other bodies; thus the acid and alkaline principles can never be brought to exhibit the same properties; nor can even the different species of earths be converted into the substance of each other.

If hypothetical reasoning was to be admitted on this occasion, it would probably appear more agreeable to the analogy of nature, to suppose that different substances are formed from the different combinations of a few simple principles in different proportions, than that the very opposite qualities of some of the rarest and most subtile fluids should depend wholly on the different form or modification of the extremely minute particles which enter into their composition.

It is proper, however, to observe, that on this subject there has hitherto appeared no decisive experimental proof on either side. The imperfection of all human efforts, and perhaps of the human faculties themselves, has hitherto confined our investigations to the properties of a few substances, the simplest which chemical analysis has been able to obtain, and which for that reason are denominated elements. See Elements.

MATTUSCHKÆA, a genus of the tetrandria monogynia class and order. The calyx is four-parted; corolla one-petalled; germ superior, four-cleft. There is one species, a herb of Guiana.

MAURITIA, the *ginkgo* or *maiden hair*, a genus of plants belonging to the natural order of palmæ. The calyx of the male is monophyllous; the corolla monopetalous, with six stamina. It is a native of Japan, where it is also known by the names of ginan and itsio. It rises with a long, erect, thick, and branched stem to the size of a walnut-tree. The bark is ash-coloured, the wood brittle or smooth, the pith soft and fungous. The leaves are large, expanded from a narrow bottom into the figure of a maiden-hair leaf, unequally parted, streaked, without fibres or nerves. From the uppermost shoots hang the flowers in long catkins that are filled with the fertilizing power; and to which succeeds the fruit, adhering to a thick fleshy pedicle, which proceeds from the bosom of the leaves. This fruit is either exactly or nearly round, and of the appearance and size of a damask plum. The substance surrounding the fruit is fleshy juice, white, very harsh, and adheres so firmly to the inclosed nut, as not to be separated from it except by putrefaction. The nut, properly termed gineau, resembles the pistachia nut, especially a Persian species named bergjes pistoia; but is almost double in size, and of the figure of an apricot-stone. The shell is somewhat white, woody, and brittle, and incloses a white loose kernel, having the sweetness of an almond, along with a degree of harshness. These kernels taken after dinner are said to promote digestion, whence they make part of the dessert in great entertainments.

MAXILLA. See Anatomy.

MAXIMUM, in mathematics, denotes the greatest quantity attainable in any given case. If a quantity conceived to be generated by motion, increases, or decreases, till it arrives at a certain magnitude or position, and then, on the contrary, grows less or greater, and it be required to determine the said magnitude or position, the question is called a problem de maximis et minimis.

Thus, let a point m move uniformly in a right line, from A towards B, and let another point n move after it, with a velocity either increasing or decreasing, but so that it may, at a certain position D, become equal to that of the former point m, moving uniformly.

$$\begin{array}{ccccccc} & & D & & C & & \\ A & \text{———————} & + & \text{———————} & + & \text{———————} & B. \\ & & n & & m & & \end{array}$$

This being premised, let the motion of n be first considered as an increasing one; in which case the distance of n behind m will continually increase, till the two points arrive at the contemporary positions C and D; but afterwards it will again decrease; for the motion of n till then being slower than at D, it is also slower than that of the preceding point m (by the hypothesis), but becoming quicker afterwards than that of m, the distance $m\,n$ (as has been already said) will again decrease; and therefore is a maximum, or the greatest of all, when the celerities of the two points are equal to each other.

But if n arrives at D with a decreasing celerity, then its motion being first swifter, and afterwards slower, than that of m, the distance $m\ n$ will first decrease and then increase, and therefore is a minimum, or the least of all, in the forementioned circumstance. Since then the distance $m\,n$ is a maximum, or a minimum, when the velocities of m and n are equal, or when that distance increases as fast through the motion of m as it decreases by that of n, its fluxion at that instant is evidently equal to nothing. Therefore, as the motion of the points m and n may be conceived such that their distance $m\,n$ may express the measure of any variable quantity whatever, it follows, that the fluxion of any variable quantity whatever, when a maximum or a minimum, is equal to nothing.

The rule therefore to determine any flowing quantity in an equation proposed, to an extreme value, is: having put the equation into fluxions, let the fluxion of that quantity whose extreme value is sought be supposed equal to nothing; by which means all those members of the equation in which it is found will vanish, and the remaining ones will give the determination of the maximum or minimum required.

Prob. I. To divide a given right line into two such parts, that their product, or rectangle, may be the greatest possible. This is the case when the line is bisected or divided into equal parts. See Fluxions.

In any mechanical engine the proportion of the power to the weight, when they balance each other, is found by supposing the engine to move, and reducing their velocities to the respective directions in which they act; for the inverse ratio of those velocities is that of the power to the weight according to the general principle of mechanics. But it is of use to determine likewise the proportion they ought to bear to each other, that when the power prevails, and the engine is in motion, it may produce the greatest effect in a given time. When the power prevails, the weight moves at first with an accelerated motion; and when the velocity of the power is invariable, its action upon the weight decreases, while the velocity of the weight increases. Thus the action of a stream of water or air upon a wheel, is to be estimated from the

tent with ourselves, and always mean the same thing by those terms we have once explained.

MATHIOLA, a genus of the pentandria monogynia class and order. The calyx is entire; corolla tubular, superior, undivided, drupe with a globular nucleus. There is one species, American.

MATRICARIA, *feverfew*, a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; there is no pappus; the calyx hemispherical and imbricated, with the marginal leaflets solid, and something sharp. There are eight species, but the only remarkable one is the parthenium or common feverfew, of which there are varieties with double flowers, with semi-double flowers, with double fistular disk and plain radius with short-rayed flowers, with rayless flowers, with rayless sulphur-coloured heads, and with finely curled leaves. All these varieties flower abundantly in June, each flower being composed of numerous hermaphrodite and female florets; the former compose the disk, the latter the radius or border, and which, in the double and fistulous kinds, are very ornamental in gardens, but of a disagreeable odour; and are all succeeded by plenty of seed in autumn. This plant has received a most extraordinary character in hysteric and other affections of the nerves, as well as for being a carminative or warm stimulating bitter. Dr. Lewis, however, thinks it inferior to camomile; with which he says it agrees in all its sensible qualities, only being somewhat weaker.

MATRICE, or MATRIX, in dyeing, is applied to the five simple colours, whence all the rest are derived or composed. These are, the black, white, blue, red, and yellow or root-colour. See DYEING.

MATRICE, or *matrices*, used by the letter-founders. See TYPE.

MATRICES. See COINING.

MATRIX, or MOTHER EARTH, the stone in which metallic ores are found enveloped.

MATROSSES, are soldiers in the train of artillery, who are next to the gunners, and assist them in loading, firing, and spunging the great guns. They carry firelocks, and march along with the store-waggons both as a guard, and to give their assistance in case a waggon should break down.

MATT, in a ship, rope-yarn, junk, &c. beaten flat and interwoven; used in order to preserve the yards from galling or rubbing in hoisting or lowering them.

MATTER. The word matter (materia, which some lexicographers have derived from mater, a mother) denotes, in its primitive sense, that unexplained something from which all those things which are objects of our senses are formed.

The term body is sometimes confounded with that of matter; but they are essentially different. Body is of Saxon origin. It is explained by the Latin words statura, pectus, truncus; and signified the person or form of a man, or other creature; whence it is plain that it ought to be confined to express a substance possessing form or figure.

Substance, both in its etymology and application, approaches nearer to the meaning of the former of these terms. It is well known to be compounded from the Latin preposition sub (under) and the verb stare (to stand). It consequently implies that which supports or stands under the different forms and appearances which are presented to our senses. It is still, however, used in a distinct and more limited sense than matter. It is generally indeed used with the article, to signify a distinct or definite portion of matter; whereas matter in the abstract implies a more confused and general idea of solidity and extension, with little or no regard to figure, proportion, or quantity.

That the whole matter of which this universe of things is composed, is essentially the same, and that the apparent differences which subsist in different bodies depend altogether on the particular distribution or disposition of the component particles, is an opinion which has been entertained by some philosophers of the highest reputation. The wonderful apparent transmutations which take place in the different processes and operations of nature do, it must be confessed, at first sight countenance this hypothesis. A plant will vegetate, and become a solid substance, in the purest water. The generation of stones in the earth, the various phenomena of petrifactions, and a multitude of other facts, contribute greatly, on a fair consideration, to diminish the absurdity of the alchemists (who seem chiefly to have rested on this hypothesis, viz. that all matter was intrinsically the same) and their hopes of converting the basest materials by the efforts of art into the most splendid and valuable of substances.

Mr. Boyle distilled the same water about two hundred times, and at the end of each distillation found a fresh deposit of earth. Margraff repeated the experiment with still greater caution. By means of two glass globes, which communicated with each other, he preserved the water while in the state of vapour from all contact with the air; and on repeated distillation, a quantity of earth of the calcareous kind was deposited at the conclusion of each process.

The extreme rarity and minuteness of the particles into which different substances may be resolved, imparts a still greater degree of probability to this hypothesis: and in general the more any body can be divided, the simpler it appears in its component parts.

We must, however, be cautious of admitting opinions which are not sanctioned by the direct test of experiment; and however plausible the opinion, the accurate observations of modern philosophy have suggested some objections to the homogenity of matter, which, without further discoveries, it will not be easy to silence.

Whatever phenomena may appear to indicate a transmutation of bodies, or a change of one substance into another, we have the utmost reason, by the latest and best experiments, to believe them merely the effect of different combinations. Thus the conversion of water and air into a solid substance, such as the body of a plant, is merely an apparent conversion; for that solid substance may, by an artificial process, be resolved again into water and air, without any real change in the principles or elementary particles of which those fluids are composed: and the formation of stones, and the phenomena of petrifactions, are accounted for upon much easier principles than that of transmutation. On the other hand, the utmost efforts of chemistry have never been able to proceed farther in the analysis of bodies than to reduce them to a few

excess of the velocity of the fluid above the velocity of the part of the engine which strikes, or from their relative velocity only. The motion of the engine ceases to be accelerated when this relative velocity is so far diminished, that the action of the power becomes equal to the resistance of the engine arising from the gravity of the matter that is elevated by it, and from friction; for when these balance each other, the engine proceeds with the uniform motion it has acquired.

Prob. II. Let a denote the velocity of the stream, u the velocity of the part of the engine which it strikes when the motion of the machine is uniform, and $a-u$ will represent their relative velocity. Let A represent the weight which would balance the force of the stream when its velocity is a, and p the weight which would balance the force of the same stream if its velocity was only $a-u$; then $p : A :: \overline{a-u}^2 : a^2$, or $p = A \times \frac{\overline{a-u}^2}{aa}$, and p shall represent the action of the stream upon the wheel. If we abstract the friction, and have regard to the quantity of the weight only, let it be equal to qA, (or be to A as q to 1); and because the motion of the machine is supposed uniform, $p = q \times A = \frac{A \times \overline{a-u}^2}{aa}$, or $q = \frac{\overline{a-u}^2}{aa}$. The momentum of this weight is $qAu = \frac{Au \times \overline{a-u}^2}{aa}$; which is a maximum when the fluxion of $\frac{u \times \overline{a-u}^2}{aa}$ vanishes, that is, when $u \times \overline{a-u}^2 - 2uu \times \overline{a-u} = 0$, or $a - 3u = 0$. Therefore, in this case, the machine will have the greatest effect if $u = \frac{a}{3}$, or the weight $qA = \frac{A \times \overline{a = u}^2}{aa} = \frac{4A}{9}$; that is, if the weight that is raised by the engine be less than the weight which would balance the power in the proportion of 4 to 9: and the momentum of the weight is $\frac{4Aa}{27}$.

Prob. III. Suppose that the given weight P (plate XCIV. Miscel. fig. 156.) descending by its gravity in the vertical line, raises a given weight W by the cord PMW (that passes over the pulley M) along the inclined plane BD, the height of which BA is given; and let the position of the plane BD be required, along which W will be raised in the least time from the horizontal line AD to B.

Let $AB = a$, $BD = x$, $t =$ time in which W describes DB; then the force which accelerates the motion of W is $P - \frac{aW}{x}$, tt is as $\frac{xx}{Px - aW}$, and if we suppose the fluxion of this quantity to vanish, we shall find $x = \frac{2aW}{P}$, or $P = \frac{2aW}{x}$; consequently the plane BD required is that upon which a weight equal to 2W would be sustained by P; or if BC be the plane upon which W would sustain P, then $BD = 2BC$. But if the position of the plane BD be given, and W being supposed variable, it be required to find the ratio of W to P, when the greatest momentum is produced in W along the given plane BD; in this case, W ought to be to P as BD to $BA + \sqrt{\overline{BD} + \overline{BA}} + \sqrt{BA}$.

Questions of this kind may be likewise demonstrated from the common elementary geometry, of which the following may serve as an example.

Prob. IV. Let a fluid, moving with the velocity and direction AC (plate XCIV. Miscel. fig 157), strike the plane CE; and suppose that this plane moves parallel to itself in the direction CB, perpendicular to CA, or that it cannot move in any other direction, then let it be required to find the most advantageous position of the plane CE, that it may receive the greatest impulse from the action of the fluid. Let AP be perpendicular to CE in P, draw AK parallel to CB, and let PK be perpendicular upon it in K; and AK will measure the force with which any particle of the fluid impels the plane EC in the direction CB. For the force of any such particle being represented by AC, let this force be resolved into AQ parallel to EC and AP perpendicular to it; and it is manifest, that the latter AP only has any effect upon the plane CE. Let this force AP be resolved into the force AL perpendicular to CB, and the force AK parallel to it; then it is manifest, that the former, AL, has no effect in promoting the motion of the plane in the direction CB; so that the latter, AK, only, measures the effort by which the particle promotes the motion of the plane CE, in the direction CB. Let EM and EN be perpendicular to CA and CB, in M and N; and the number of particles moving with directions parallel to AC, incident upon the plane CE, will be as EM. Therefore the effort of the fluid upon CE, being as the force of each particle, and the number of particles together, it will be as $AK \times EM$; or, because AK is to AP (= EM) as EN to CE, as $\frac{EM^2 EM \times EN}{CE}$; so that CE being given, the problem is reduced to this, to find when $EM^2 \times EN$ is the greatest possible, or a maximum. But because the sum of EM^2 and of EN^2 ($= CM^2$) is given, being always equal to CE^2, it follows that $EN^2 \times EM^4$ is greatest when $EN^2 = \frac{1}{3} CE^2$; for when the sum of two quantities AC and CB (fig 158.) was given, $AC \times BC^2$ is greatest when $AC = \frac{1}{3} AB$, as will be very evident if a semicircle is described upon AD. But when $EN^2 \times EM^2$ is greatest, its square root $EN \times EM^2$ is of necessity at the same time greatest. Therefore the action of the fluid upon the plane CE, in the direction CB, is greatest when $EN^2 = \frac{1}{3} CE^2$, and consequently $LM^2 = \frac{2}{3} CE^2$; that is, when EM, the sine of the angle ACE, in which the stream strikes the plane, is to the radius, as $\sqrt{2}$ to $\sqrt{3}$; in which case it easily appears from the trigonometrical tables, that this angle is of 54° 44′

Several useful problems in mechanics may be resolved by what we have just now shown. If we represent the velocity of the wind by AC, a section of the sail of a windmill perpendicular to its length by CE, as it follows from the nature of the engine, that its axis ought to be turned directly to the wind, and the sail can only move in a direction perpendicular to the axis, it appears, that, when the motion begins, the wind will have the greatest effect to produce this motion, when the angle ACE, in

which the wind strikes the sail, is of 54° 44′. In the same manner, if CB represent the direction of the motion of a ship, or the position of her keel, abstracting from her lee-way, and AC be the direction of the wind perpendicular to her way, then the most advantageous position of the sail CE, to promote her motion in the direction CB, is when the angle ACE, in which the wind strikes the sail, is of 54° 44′. The best position of the rudder, where it may have the greatest effect in turning round the ship, is determined in like manner.

Prob. V. To find the internal dimensions of a cylindrical cup, whose capacity is equal to a, when the cup is made with the least possible quantity of silver of a given thickness.

Put the diameter $= x$; and .7854 (the area of the circle whose diameter is 1) $= c$: then, by El. xii. 2, $cx^2 =$ the area of the bottom, and therefore $\frac{a}{cx^2} =$ the altitude; but $4cx =$ the circumference of the bottom, and therefore $4cx \times \frac{a}{cx^2} = \frac{4a}{x} =$ the inside curve superficies. Hence $cx^2 + \frac{4a}{x} =$ the whole inside superficies, which is a minimum; and therefore its fluxion is $= 0$: that is, $2cx\dot{x} - \frac{4a\dot{x}}{x^2} = 0$, or $2cx^3\dot{x} - 4a\dot{x} = 0$, or $cx^3 - 2a = 0$, therefore $cx^3 = 2a$, and $x = \sqrt[3]{\frac{2a}{c}} =$ diameter. By substituting this quantity for x in $\frac{a}{cx^2}$, we have $\frac{a}{c \times \overline{\frac{2a}{c}}|^{\frac{2}{3}}}$

$$= \frac{a \times \overline{\frac{2a}{c}}|^{\frac{1}{3}}}{c \times \frac{2a}{c}} = \frac{a}{c} \times \frac{\overline{\frac{2a}{c}}|^{\frac{1}{3}}}{\frac{2a}{c}} = \frac{ac}{2ac} \times \overline{\frac{2a}{c}}|^{\frac{1}{3}} = \tfrac{1}{2} \times \overline{\frac{2a}{c}}|^{\frac{1}{3}} =$$ altitude. Since then the diameter is $\overline{\frac{2a}{c}}|^{\frac{1}{3}}$ and the altitude is half that quantity, they will be to one another as 2 to 1, to answer the conditions of the problem.

Prob. VI. To find the greatest cone that can be inscribed in a given sphere.

Let AD (plate Miscel. fig. 159) the diameter of the sphere $= a$; 7854 (the area of a circle whose diameter is 1) $= c$; and AC, the altitude of the cone, $= x$; then CD $= a - x$. By El. iii. 35, AC $\times$ CD $=$ CB², that is, $x \times a - x = ax - x^2 =$ CB²; but the square of the diameter is four times the square of the radius; therefore, by El. xii. 2, $4acx - 4cx^2 =$ the area of the cone's base, which, by El. xii. 10, drawn into $\frac{1}{3}x$, is $\frac{4}{3}acx^2 - \frac{4}{3}cx^3 =$ the cone's solidity, which is a maximum; therefore, by taking away what is common, we get $ax^2 - x^3$ a maximum, the fluxion of which is $= 0$, that is, $2ax\dot{x} - 3x^2\dot{x} = 0$, or $2a = 3x$, and $x = \frac{2a}{3}$. So that the cone will be a maximum, when its altitude is equal to two-thirds of the sphere diameter.

MEAD, an agreeable liquor made of honey and water. See Honey.

There are many receipts for making mead, of which the following is one of the best. Take four gallons of water, and as much honey as will make it bear an egg; add to this the rind of three lemons, boil it, and scum it well as it rises. Then take it off the fire, and add the three lemons cut in pieces; pour it into a clean tub or open vessel, and let it work for three days; then scum it well, and pour off the clear part into a cask, and let it stand open till it ceases to make a hissing noise; then stop it up close, and in three months time it will be fine and fit for bottling. If you would give it a finer flavour, take cloves, mace, and nutmeg, of each four drams; beat them small, tie the powder in a piece of cloth, and put it into the cask.

MEADOW. See Husbandry.

MEAN, a middle state between two extremities; as a mean motion, mean distance, arithmetical mean, geometrical mean, &c.

Arithmetical Mean, is half the sum of the extremes. So, 4 is an arithmetical mean between 2 and 6, or between 3 and 5, or between 1 and 7; also an arithmetical mean between a and b is $\frac{a+b}{2}$, or $\frac{1}{2}a + \frac{1}{2}b$.

Geometrical Mean, commonly called a mean proportional, is the square root of the product of the two extremes; so that, to find a mean proportional between two given extremes, multiply these together, and extract the square root of the product. Thus, a mean proportional between 1 and 9, is $\sqrt{1 \times 9} = \sqrt{9} = 3$; a mean between 2 and $4\frac{1}{2}$ is $\sqrt{2 \times 4\frac{1}{2}} = \sqrt{9} = 3$ also; the mean between 4 and 6 is $\sqrt{4 \times 6} = \sqrt{24}$; and the mean between a and b is $\sqrt{ab}$.

The geometrical mean is always less than the arithmetical mean between the same two extremes. So the arithmetical mean between 2 and $4\frac{1}{2}$ is $3\frac{1}{4}$, but the geometrical mean is only 3. To prove this generally, let a and b be any two terms, a the greater, and b the less: then, universally, the arithmetical mean $\frac{a+b}{2}$ shall be greater than the geometrical mean $\sqrt{ab}$, or $a + b$ greater than $2\sqrt{ab}$. For, by

squaring both, they are $a^2 + 2ab + b^2 > 4ab$;
subtr. $4ab$ from each, then $a^2 - 2ab + b^2 > 0$,
that is, $(a - b)^2 > 0$.

To find a Mean Proportional geometrically, between two given lines M and N. Join the two given lines together at C, in one continued line AB; upon the diameter AB describe a semicircle, and erect the perpendicular CD; which will be the mean proportional between AC and CB, or M and N.

To find two Mean Proportionals between two given extremes. Multiply each extreme by the square of the other, viz. the greater extreme by the square of the less, and the less extreme by the square of the greater; then extract the cube root out of each product, and the two roots will be the two mean proportionals sought. That is, $\sqrt[3]{a^2b}$ and $\sqrt[3]{ab^2}$ are the two means between a and b. So, between 2 and 16, the two mean proportionals are 4 and 8; for $\sqrt[3]{2^2 \times 16} = \sqrt[3]{64} = 4$, and $\sqrt[3]{2 \times 16^2} = \sqrt[3]{512} = 8$.

In a similar manner we proceed for three means, or four means, or five means, &c.; from all which it appears,

that the series of the several numbers of mean proportionals between a and b will be as follows: viz.

1 mean, $\sqrt{ab}$;
2 means, $\sqrt[3]{a^2b}$. $\sqrt[3]{ab^2}$;
3 means, $\sqrt[4]{a^2b^2}$. $\sqrt[4]{a^2b}$, $\sqrt[4]{ab^3}$;
4 means, $\sqrt[5]{a^4b}$. $\sqrt[5]{a^2b^2}$, $\sqrt[5]{a^2b^3}$, $\sqrt[5]{ab^4}$;
5 means, $\sqrt[6]{a^5b}$, $\sqrt[6]{a^4b^2}$, $\sqrt[6]{a^3b^3}$, $\sqrt[6]{a^2b^4}$, $\sqrt[6]{ab^5}$:
&c. &c.

Harmonical MEAN, is double a fourth proportional to the sum of the extremes, and the two extremes themselves a and b: thus, as $a + b : a :: 2b : \frac{2ab}{a+b} = m$, the harmonical mean between a and b. Or it is the reciprocal of the arithmetical mean between the reciprocals of the given extremes; that is, take the reciprocals of the extremes a and b, which will be $\frac{1}{a}$ and $\frac{1}{b}$; then take the arithmetical mean between these reciprocals, or half their sum, which will be $\frac{1}{2a} + \frac{1}{2b}$, or $\frac{a+b}{2ab}$; lastly, the reciprocal of this is $\frac{2ab}{a+b} = m$, the harmonical mean: for arithmeticals and harmonicals are mutually reciprocals of each other;

so that if a, m, b, &c. be arithmeticals,

then shall $\frac{1}{a}$, $\frac{1}{m}$, $\frac{1}{b}$, &c. be harmonicals; or if the former be harmonicals, the latter will be arithmeticals.

For example, to find a harmonical mean between 2 and 6: here $a = 2$, and $b = 6$; therefore $\frac{2ab}{a+b} = \frac{2 \times 2 \times 6}{2 + 6} = \frac{24}{8} = 3 = m$, the harmonical mean sought between 2 and 6.

Pappus has shown a curious similiarity that subsists between the three different sorts of mean: a, m, b, being three continued terms, either arithmeticals, geometricals, or harmonicals, then in the

Arithmeticals $a : a :: a - m : m - b$
Geometricals $a : m :: a - m : m - b$
Harmonicals $a : b :: a - m : m - b$.

MEASLES. See MEDICINE.

MEASURE *of an angle*, is an arch described from the vertex in any place between its legs. Hence angles are distinguished by the ratio of the arches, described from the vertex between the legs to the peripheries. Angles then are distinguished by those arches; and the arches are distinguished by their ratio to the periphery: thus an angle is said to be so many degrees as there are in the said arch. See ANGLE.

MEASURE *of a figure*, or plane surface, is a square whose side is one inch, one foot, one yard, or some other determined length. Among geometricians, it is usually a rod called a square rod, divided into 10 square feet, and the square feet into 10 square digits.

MEASURE *of a solid*, is a cube whose side is one inch, foot, yard, or any other determinate length. In geometry it is a cubic perch, divided into cubic feet, digits, &c. Hence cubic measures, or measures of capacity. See SPHERE, CUBE, &c.

MEASURE *of velocity*, in mechanics, the space passed over by a moving body in a given time. To measure a velocity therefore, the space must be divided into as many equal parts as the time is conceived to be divided into; the quantity of space answering to such a part of time is the measure of the velocity.

MEASURE, in geometry, denotes any quantity assumed as one, or unity, to which the ratio of the other homogenous or similar quantities is expressed.

Measures in a legal and commercial sense are various, according to the various kinds and dimensions of the things measured. Hence arise lineal or longitudinal measures, for lines or lengths, square measures, for areas or superficies; and solid or cubic measures, for bodies and their capacities; all which again are very different in different countries and in different ages, and even many of them for different commodities. Whence arise other divisions of ancient and modern measures, domestic and foreign ones, dry measures, liquid measures, &c.

I. *Long measures, or measures of application.*

1. The English and Scotch standards.

The English lineal standard is the yard, containing 3 English feet, equal to 3 Paris feet 1 inch and $\frac{3}{12}$ of an inch, or $\frac{7}{9}$ of a Paris ell. The use of this measure was established by Henry I. of England, and the standard taken from the length of his own arm. It is divided into 36 inches, and each inch is supposed equal to 3 barleycorns. When used for measuring cloth, it is divided into 4 quarters, and each quarter subdivided into 4 nails. The English ell is equal to a yard and a quarter, or 45 inches, and is used in measuring linens imported from Germany and the Low-countries.

The Scots elwand was established by king David I. and divided into 37 inches. The standard is kept in the council-chamber of Edinburgh, and being compared with the English yard, is found to measure $37\frac{1}{5}$ inches; and therefore the Scots inch and foot are larger than the English, in the proportion of 180 to 185; but this difference being so inconsiderable, is seldom attended to in practice. The Scots ell, though forbidden by law, is still used for measuring some coarse commodities, and is the foundation of the land-measure of Scotland.

Itinerary measure is the same both in England and Scotland. The length of the chain is 4 poles, or 22 yards; 80 chains make a mile. The old Scots computed miles were generally about a mile and a half each.

The reel for yarn is $2\frac{1}{2}$ yards, or 10 quarters, in circuit; 120 threads make a cut; 12 cuts make a hasp or hank, and 4 hanks make a spindle.

2. The French standard was formerly the aune or ell, containing 3 Paris feet, 7 inches, 8 lines, or 1 yard $\frac{2}{7}$ English; the Paris foot royal exceeding the English by $\frac{68}{1000}$ parts, as in one of the following tables. This ell is divided two ways, viz. into halves, thirds, sixths, and twelfths; and into quarters, half-quarters, and sixteenths.

The French, however, have also formed an entirely new system of weights and measures, according to the following table:

Proportion of the measures of each species to its principal measure or unity.	First part of the name which indicates the proportion to the principal measure or unity.	PRINCIPAL MEASURES OR UNITIES.				
		Length.	Capacity.	Weight.	Agrarian.	For firewood.
10,000 1,000 100 10 1 0.1 0.01 0.001	Myria Kilo Hecto Deca —— Deci Centi Milli	Metre.	Litre.	Gramme.	Are.	Stere.
Proportion of the principal measures between themselves, and the length of the meridian.		10,000,000 part of the dist. from the pole to the equator.	A decimetre cube.	Weight of a centimetre cube of distilled water.	100 square metres.	One cubic metre.
Value of the principal measures in the ancient French measures.		3 feet 11 lines and $\frac{1}{2}$ nearly.	1 pint and $\frac{1}{20}$, or 1 liton and $\frac{1}{4}$ nearly.	18 grains and 841,000 parts.	Two square perches des eaux et foret.	1 demi-voie, or $\frac{1}{4}$ of a cord des eaux et foret.
Value in English measures.		Inches 39,383	61.083 inches, which is more than the wine and less than the beer quart.	22.966 grains.	11.968 square yards.	

3. The English avoirdupois pound weighs 7004 troy grains; whence the avoirdupois ounce, whereof 16 make a pound, is found equal to 437.75 troy grains. And it follows, that the troy pound is to the avoirdupois pound as 88 to 107 nearly; for as 88 to 107, so is 5760 to 7003.636: that the troy ounce is to the avoirdupois ounce, as 80 to 73 nearly; for as 80 to 73, so is 480 to 438: and, lastly, that the avoirdupois pound and ounce are to the Paris two-marc weight and ounce, as 63 to 68 nearly; for as 63 to 68, so is 7004 to 7559.873. See Weight. 4. The Paris foot expressed in decimals is equal to 1.0654 of the English foot, or contains 12.785 English inches.

3. The standard in Holland, Flanders, Sweden, a good part of Germany, many of the Hanse-towns, as Dantzic and Hamburgh, and at Geneva, Franckfort, &c. is likewise the ell; but the ell in all these places differs from the Paris ell. In Holland it contains one Paris foot 11 lines, or 4-sevenths of the Paris ell. The Flanders ell contains 2 feet 1 inch 5 lines and half a line, or 7-twelfths of the Paris ell. The ell of Germany, Brabant, &c. is equal to that of Flanders.

4. The Italian measure is the bracchio, brace, or fathom. This obtains in the states of Modena, Venice, Florence, Lucca, Milan, Mantua, Bologna, &c. but is of different lengths. At venice it contains 1 Paris foot, 11 inches, 3 lines, or 8-fifteenths of the Paris ell. At Bologna, Modena, and Mantua, the brace is the same as at Venice. At Lucca it contains 1 Paris foot, 9 inches, 10 lines, or half a Paris ell. At Florence it contains 1 foot, 9 inches, four lines, or 49-hundredths of a Paris ell. At Milan, the brace for measuring of silks is 1 Paris foot, 7 inches, 4 lines, or 4 ninths of a Paris ell; that for woollen cloths is the same with the ell of Holland. Lastly, at Bergama, the brace is 1 foot 7 inches, 6 lines, or 5 ninths of a Paris ell. The usual measure at Naples, however, is the anna, containing 6 feet, 10 inches, and 2 nes, or one Paris ell and 15-seventeenths.

5. The Spanish measure is the vara or yard, in some places called the barra; containing 17 twenty-fourths of the Paris ell. But the measure in Castile and Valencia is the pan, span, or palm; which is used, together with the canna, at Genoa. In Arragon, the vara, is equal to a Paris ell and a half, or 5 feet, 5 inches, 6 lines.

6. The Portuguese measure is the cavedos, containing 2 feet, 11 lines, or four-sevenths of a Paris ell; and the vara, 106 whereof make a 100 Paris ell.

7. The Piedmontese measure is the ras, containing 1 Paris foot, 9 inches, 10 lines, or half a Paris ell. In Sicily, their measure is the canna, the same with that of Naples.

8. The Muscovite measures are the cubit, equal to 1 Paris foot, 4 inches, 2 lines; and the arcin, two whereof are equal to 3 cubits.

9. The Turkish and Levant measures are the picq, containing 2 feet, 2 inches, and 2 lines, or three-fifths of the Paris ell. The Chinese measure is the cobre, ten whereof are equal to three Paris ells. In Persia, and some parts of the Indies, the gueze, of which there are two kinds; the royal gueze, called also the gueze monkelser, containing 2 Paris feet, 10 inches, 11 lines, or four-fifths of the Paris ell; and the shorter gueze, called simply gueze, only two-thirds of the former. At Goa and Ormuz, the measure is the vara, the same with that of the Portuguese, having been introduced by them. In Pegu, and some other parts of the Indies, the cando or candi, equal to the ell of Venice. At Goa, and other parts, they

use a larger cando, equal to 17 Dutch ells, exceeding that of Babel and Balsora by $\frac{7}{8}$ per centum, and the vara by $6\frac{1}{2}$. In Siam, they use the ken, short of three Paris feet by one inch. The ken contains two soks, the sok two keubs, the keub 12 nious or inches, the niou to be equal to eight grains of rice, *i. e.* to about nine lines. At Camboia they use the haster; in Japan the tatam; and the span on some of the coasts of Guinea.

English MEASURES of Length.

A TABLE

Of the Measures of Length of the principal Places in Europe, compared with the English Yard.

			Eng. yard.
100	Aunes,	or ells of England, equal to	125
100		of Holland or Amsterdam	75
100		of Brabant or Antwerp	76
100		of France	$128\frac{1}{4}$
100		of Hamburgh, Francfort, &c.	$62\frac{1}{2}$
100		of Breslau	60
100		of Dantzick	$66\frac{3}{4}$
100		of Bergen and Drontheim	$68\frac{1}{4}$
100		of Sweden or Stockholm	$65\frac{3}{4}$
100		of St. Gall, for linens	$87\frac{1}{2}$
100		of ditto, cloths	67
100		of Geneva	$124\frac{3}{4}$
100	Canes	of Marseilles and Montpelier	$214\frac{1}{2}$
100		of Toulouse & High Languedoc	200
100		of Genoa, of 9 palms	$245\frac{1}{4}$
100		of Rome	$227\frac{1}{4}$
100	Varas	of Spain	$93\frac{3}{4}$
100		of Portugal	123
100	Cavidos	of Portugal	75
102	Brasses	of Venice	$73\frac{1}{2}$
100		of Bergamo, &c.	$71\frac{1}{4}$
100		of Florence and Leghorn	64
100		of Milan	$58\frac{1}{2}$

N. B. The aunes or ells of Amsterdam, Haerlem, Leyden, the Hague, Rotterdam, and other cities of Holland, as also that of Nuremberg, being all equal, are comprehended under that of Amsterdam; as those of Osnaburg are under those of France; and those of Bern and Basil are equal to those of Hamburg, Francfort, and Leipsic.

For the subdivisions and multiples of each of these measures of length, see the article AUNE.

For the proportion of the feet of the principal nations in Europe, compared with the English foot, see the article FOOT.

Square, or *Superficial* MEASURES. English square or superficial measures are raised from the yard of 36 inches multiplied into itself, and thus producing 1296 square inches in the square yard: the divisions of this are square feet and inches; and the multiples, poles, roods, and acres, as in the following table:

English SQUARE MEASURES.

Inches						
144	Foot					
1296	9	Yard				
3600	25	$2\frac{7}{9}$	Pace			
39204	$272\frac{1}{4}$	$30\frac{1}{4}$	10.89	Pole		
1568160	10890	1210	435.6	40	Rood	
6272640	43560	4840	1743.6	160	4	Acre.

Roman SQUARE-MEASURE reduced to English.

The integer was the jugerum or acre, which the Romans divided like the libra or as: thus, the jugerum contained

	Square feet.	Scruples.	English roods.	Square poles.	Square feet.
As	28800	288	2	18	[illegible]0.05
Deunx	26400	264	2	10	183.85

Quadrans	7200	72	0	24	198.64
Sextans	4800	48	0	16	132.43
Uncia	2400	24	0	8	66.21

Note. Actus major was 14400 square feet, equal to a semis; clima, 3600 square feet, equal to a sescuncia; and actus minimus equal to a sextans.

Cubical MEASURES, *or Measures of capacity for liquids.* The English measures were originally raised from troy-weight: it being enacted by several statutes that eight pounds troy of wheat gathered from the middle of the ear, and well dried, should weigh a gallon of wine-measure, the divisions and multiples whereof were to form the other measures; at the same time it was also ordered, that there should be but one liquid measure in the kingdom: yet custom has prevailed, and there having been introduced a new weight, viz. the avoirdupois, we have now a second standard gallon adjusted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy weight. From this latter standard are raised two several measures, the one for ale, the other for beer.

The sealed gallon at Guildhall, which is the standard for wines, spirits, oils, &c. is supposed to contain 231 cubic inches; and on this supposition the other measures raised therefrom, will contain as in the table underneath; yet, by actual experiment, made in 1688, before the lord-mayor and the commissioners of excise, this gallon was found to contain only 224 cubic inches: it was however agreed to continue the common supposed contents of 231 cubic inches; so that all computations stand on their old footing. Hence, as 12 is to 231, so is $14\frac{1}{2}\frac{2}{0}$ to $281\frac{1}{2}$ the cubic inches in the ale gallon: but in effect the ale quart contains $70\frac{1}{2}$ cubic inches, on which principle the ale and beer gallon will be 282 cubic inches. The several divisions and multiples of these measures, and their proportions, are exhibited in the following tables:

Measure *for horses*, is the hand, which by statute contains four inches.

MEATUS AUDITORIUS. See Anatomy.

MECHANICS, that branch of practical mathematics which considers motion and moving powers, their nature and laws, with their effects in machines.

The term mechanics is equally applied to the doctrine of the equilibrium of powers, more properly called statics; and to that science which treats of the generation and communication of motion, which constitutes mechanics strictly so called. See Statics, Power, Motion, &c.

The knowledge of mechanics is one of those things, says Mr. Mac Laurin, that serve to distinguish civilized nations from barbarians. It is by this science that the utmost improvement is made of every power and force in nature; and the motions of the elements, water, air, and fire, are made subservient to the various purposes of life; for however weak the force of man appears to be, when unassisted by this art; yet, with its aid, there is hardly any thing above his reach. It is distinguished by sir Isaac Newton into practical and rational mechanics; the former of which treats of the mechanical powers, viz. the lever, balance, axis and wheel, pulley, wedge, screw, and inclined plane.

Rational mechanics comprehends the whole theory of motion, shows when the powers or forces are given how to determine the motions that are produced by them; and conversely when the phænomena of the motions are given, how to trace the powers or forces from which they arise.

Mechanical powers are simple engines that enable men to raise weights, to move heavy bodies, and overcome resistances, which they could not do with their natural strength alone. Their importance to society is incalculable. Every machine whatever is composed of one or more of them, sometimes of several combined together.

In considering this science, it will be necessary at first to take some things for granted that are not strictly true; and after the theory is established, to make the proper allowances for them.

1. That a small portion of the earth's surface, which is spherical, may be considered as a plane. 2. That all bodies be supposed to descend in lines parallel to each other; for though all bodies really tend to the centre of the earth, yet the distance from which they fall, is comparatively so small, that their inclination towards each other is inconsiderable. 3. That all planes be considered as perfectly smooth; levers to be inflexible, and without thickness or weight; cords perfectly pliable; and machines without friction and inertia.

Three things are always to be considered in treating of mechanical engines; the weight to be raised, the power by which it is to be raised, and the instrument or engine by which this is to be effected.

The mechanical powers are generally reckoned six; the lever, the pulley, the wheel and axis, the inclined plane, the wedge, and the screw.

These perhaps may be reduced to two; for the pulley and wheel are only assemblages of levers, and the wedge and screw are inclined planes.

To calculate the power of a machine, it is usually considered in a state of equilibrium; that is, in the state when the power which is to overcome the resistance just balances it. Having discovered what quantity of power will be requisite for this purpose, it will then be necessary to add so much more as to overcome the friction and weight of the machine itself, and to give the necessary velocity.

The *lever* is the simplest of all machines; and is only a straight bar of iron, wood, or other material, supported on, and moveable round, a prop called the fulcrum.

In the lever there are three circumstances to be principally attended to: 1. The fulcrum, or prop, by which it is supported, or on which it turns as an axis, or centre of motion: 2. The power to raise and support the weight: 3. The resistance or weight to be raised or sustained.

The points of suspension are those points where the weights really are, or from which they hang freely. The power and the weight are always supposed to act at right angles to the lever, except it is otherwise expressed.

The lever is distinguished into three sorts, according to the different situations of the fulcrum or prop, and the power, with respect to each other. 1. When the prop is placed between the power and the weight. 2. When the prop is at one end of the lever, the power at the other, and the weight between them. 3. When the prop is at one end, the weight at the other, and the power applied between them.

A poker, in stiring the fire, is a lever of the first sort: the bar of the grate upon which it rests is the fulcrum the fuel, the weight to be overcome; and the hand is the power. The lever of the first kind is principally used for loosening large stones; or to raise great weights to small heights, in order to get ropes under them, or other means of raising them to still greater heights; it is the most common species of lever.

ABC, Plate LXXXIII. Mechanics, fig. 1. is this lever, in which B is the fulcrum, A the end at which the power is applied, and C the end where the weight acts.

To find when an equilibrium will take place between the power and the weight, in this as well as in every other species of lever, it is necessary to recollect, that when the momenta, or quantities of force, in two bodies are equal, they will balance each other. Now let us consider when this will take place in the lever. Suppose the lever AB (fig. 2) to be turned on its axis, or fulcrum, so as to come into the situation DC; as the end D is farthest from the centre of motion, and as it has moved through the arch AD in the same time as the end B moved through the arch BC, it is evident that the velocity of AB must have been greater than that of B. But the momenta being the products of the quantities of matter multiplied into the velocities, the greater the velocity, the less the quantity of matter need be to get the same product. Therefore, as the velocity of A is the greatest, it will require less matter to produce an equilibrium than B.

Let us next see how much more weight B will require than A to balance it. As the radii of circles are in proportion to their circumferences, they are also proportionate to similar parts of them; therefore, as the arches AD, CB, are similar, the radius or arm DE bears the same proportion to EC that the arch AD bears to CB. But the arches AD and CB represent the velocities of the ends of the lever, because they are the spaces which they moved over in the same time; therefore the arms DE and EC may also represent these velocities.

It is evident then, that an equilibrium will take place when the length of the arm AE multiplied into the power A, shall equal EB multiplied into the weight B; and consequently, that the shorter EB is, the greater must be the weight B; that is, the power and the weight must be to each other inversely, as their distances from the fulcrum. Thus, suppose AE, the distance of the power from the prop, to be 20 inches, and EB, the distance of the weight from the prop, to be eight inches, also the weight to be raised at B to be five pounds, then the power to be applied at A must be two pounds; because the distance of the weight from the fulcrum eight, multiplied into the weight five, makes 40; therefore 20, the distance of the power from the prop, must be multiplied by two, to get an equal product, which will produce an equilibrium.

It is obvious, that while the distance of the power from the prop exceeds that of the weight from the prop, a power less than the weight will raise it, so that then the lever affords a mechanical advantage: when the distance of the power is less than that of the weight from the prop, the power must be greater than the weight to raise it; when both the arms are equal, the power and the weight must be equal, to be in equilibrio.

The second kind of lever, when the weight is between the fulcrum and the power, is represented by fig. 3. in which A is the fulcrum, B the weight, and C the power. The advantage gained by this lever, as in the first, is as great as the distance of the power from the prop exceeds the distance of the weight from it. Thus if the point *a*, on which the power acts, is seven times as far from A as the point *b*, on which the weight acts, then one pound applied at C will raise seven pounds at B.

This lever shows the reason why two men carrying a burden upon a stick between them, bear shares of the burden which are to one another in the inverse proportion of their distances from it. For it is well known, that the nearer either of them is to the burden, the greater share he bears of it; and if he goes directly under it, he bears the whole. So if one man is at A, and the other at *a*, having the pole or stick resting on their shoulders; if the burden or weight B is placed five times as near the man at A, as it is to the man at *a*, the former will bear five times as much weight at the latter.

This is likewise applicable to the case of two horses of unequal strength to be so yoked, that each horse may draw a part proportional to his strength; which is done by so dividing the beam they pull, that the point of traction may be as much nearer to the stronger horse than to the weaker, as the strength of the former exceeds that of the latter.

To this kind of lever may be reduced oars, rudders of ships, doors turning upon hinges, cutting-knives which are fixed at the point, &c.

If in this lever we suppose the power and weight to change places, so that the power may be between the weight and the prop, it will become a lever of the third kind; in which, that there may be a balance between the power and the weight, the intensity of the power must exceed the intensity of the weight just as much as the distance of the weight from the prop exceeds the distance of the power. Thus, let E (fig. 4.) be the prop of the lever EF, and W a weight of one pound, placed three times as far from the prop as the power P acts at F, by the cord going over the pulley D: in this case the power must be equal to three pounds, in order to support the weight of one pound.

To this sort of lever are generally referred the bones of a man's arm; for when he lifts a weight by the hand, the muscle that exerts its force to raise that weight is fixed to the bone about one-tenth part as far below the elbow as the hand is. And the elbow being the centre round which the lower part of the arm turns, the muscle must therefore exert a force ten times as great as the weight that is raised.

As this kind of lever is a disadvantage to the moving power, it is used as little as possible; but in some cases it cannot be avoided, such as that of a ladder, which being fixed at one end, is by the strength of a man's arms reared against a wall.

What is called the hammer-lever differs in nothing but its form, from a lever of the first kind. Its name is derived from its use, that of drawing a nail out of wood by a hammer.

Suppose the shaft of a hammer to be five times as long as the iron part which draws the nail, the lower part resting on the board as a fulcrum; then by pulling backwards the end of the shaft, a man will draw a nail with one-fifth part of the power that he must use to pull it out with a pair of pincers, in which case the nail would move as fast as his hand; but with the hammer the hand moves five times as much as the nail, by the time that the nail is drawn out.

Let ACB (fig. 5.) represent a lever of this sort, bent at C, which is its prop, or centre of motion. P is a power acting upon the longer arm AC, at A, by the means of the cord DA going over the pulley D; and W is a weight or resistance acting upon the end B of the shorter arm CB. If the power is to the weight as CB is to CA, they are in equilibrio: thus, suppose W to be five pounds, acting at the distance of one foot from the centre of motion C, and P to be one pound, acting at A, five feet from the centre C; the power and weight will just balance each other.

Thus we see, that in every species of lever there will be an equilibrium, when the power is to the weight, as the distance of the weight from the fulcrum is to the distance of the power from the fulcrum.

In making experiments on the mechanic powers, some difficulties arise from the weight of the materials; but as it is impossible to find any that are without weight, we take care that they are perfectly balanced themselves, before the weights and powers are applied. The bar, therefore, used in making experiments on levers, has the short end so much thicker than the long arm, as will be sufficient to balance it on the prop.

Hitherto we have supposed that the power and weight acted perpendicularly upon the lever; but they do not, they act with less force upon it; the power should, therefore, if possible, be always made to act at right angles to the lever.

If several levers are combined together in such a manner, as that a weight being appended to the first lever, may be supported by a power applied to the last, as in fig. 6. (which consists of three levers of the first kind, and is so contrived, that a power applied at the point L of the lever C, may sustain a weight at the point S of lever A), the power must here be to the weight, in ratio, or proportion, compounded of the several ratios, which those powers that can sustain the weight by the help of each lever, when used singly and apart from the rest, have to the weight. For instance: if the power which can sustain the weight P by the help of the lever A, is to the weight as 1 to 5; and if the power which can sustain the same weight by the lever B alone, is to the weight as 1 to 4; and if the power which could sustain the same weight by the lever C, is to the weight as 1 to 5; then the power which will sustain the weight by the help of the three levers joined together, will be to the weight in a proportion consisting of the several proportions multiplied together, of 1 to 5, 1 to 4, and 1 to 5; that is, of 1 to 100.

For since, in the lever A, a power equal to one-fifth of the weight P pressing down the lever at L, is sufficient to balance the weight; and since it is the same thing whether that power is applied to the lever A at L, or the lever B at S, the point S bearing on the point L; a power equal to one-fifth of the weight P, being applied to the point S of the lever B, will support the weight; but one-fourth of the same power being applied to the

point L of the lever B, and pushing the same upward, will as effectually depress the point S of the same lever, as if the whole power was applied at S; consequently a power equal to one-fourth of one-fifth, that is, one-twentieth of the weight P, being applied to the point L of the lever B, and pushing up the same, will support the weight; in like manner, it matters not whether that force is applied to the point L of the lever B, or to the point S of the lever C, since, if S be raised, L, which rests on it, must be raised also; but one-fifth of the power applied at the point L of the lever C, and pressing it downwards, will as effectually raise the point S of the same lever, as if the whole power was applied at S, and pushed up the same; consequently a power equal to one-fifth of one-twentieth, that is, one-hundredth part of the weight P, being applied to the point L of the lever C, will balance the weight at the point S of the lever A.

The balance, an instrument of very extensive use in comparing the weights of bodies, is a lever of the first kind, whose arms are of equal length. The points from which the weights are suspended being equally distant from the centre of motion, will move with equal velocity; consequently, if equal weights are applied, their momenta will be equal, and the balance will remain in equilibrio.

In order to have a balance as perfect as possible, it is necessary to attend to the following circumstances:

1. The arms of the beam ought to be exactly equal, both as to weight and length.

2. The points from which the scales are suspended should be in a right line, passing through the centre of gravity of the beam: for by this the weights will act directly against each other, and no part of either will be lost on account of any oblique direction.

3. If the fulcrum, or point upon which the beam turns, is placed in the centre of gravity of the beam, and if the fulcrum and the points of suspension are in the same right line, the balance will have no tendency to one position more than another, but will rest in any position it may be placed in, whether the scales are on or off, empty or loaded.

If the centre of gravity of the beam, when level, is immediately above the fulcrum, it will overset by the smallest action; that is, the end which is lowest will descend; and it will do this with more swiftness, the higher the centre of gravity is, and the less the points of suspension are loaded.

But if the centre of gravity of the beam is immediately below the fulcrum, the beam will not rest in any position but when level; and if disturbed from that position, and then left at liberty, it will vibrate, and at last come to rest on the level. In a balance, therefore, the fulcrum ought always to be placed a little above the centre of gravity. Its vibrations will be quicker, and its horizontal tendency stronger, the lower the centre of gravity, and the less the weight upon the points of suspension.

4. The friction of the beam upon the axis ought to be as little as possible; because, should the friction be great, it will require a considerable force to overcome it; upon which account, though one weight should a little exceed the other, it will not preponderate, the excess not being sufficient to overcome the friction, and bear down the beam. The axis of motion should be formed with an edge like a knife, and made very hard; these edges are at first made sharp, and then rounded with a fine hone, or piece of buff leather, which causes a sufficient bluntness, or rolling edge. On the regular form and excellence of this axis, depends chiefly the perfection of the instrument.

5. The pivots which form the axis or fulcrum, should be in a straight line, and at right angles to the beam.

6. The arms should be as long as possible, relatively to their thickness, and the purposes for which they are intended; as the longer they are, the more sensible is the balance. They should also be made as stiff and inflexible as possible; for if the beam is too weak, it will bend, and become untrue.

7. The rings, or the piece on which the axis bears, should be hard and well polished, parallel to each other, and of an oval form, that the axes may always keep its proper bearing, or remain always at the lowest point.

Very delicate balances are not only useful in nice experiments, but are likewise much more expeditious than others in common weighing. If a pair of scales with a certain load is barely sensible to one-tenth of a grain, it will require a considerable time to ascertain the weight to that degree of accuracy, because the turn must be observed several times over, and is very small. But if no greater accuracy was required, and scales were used which would turn with one-hundreth of a grain, a tenth of a grain more or less would make so great a difference in the turn, that it would be seen immediately.

The statera, or Roman steel-yard, is a lever of the first kind, and is used for finding the weights of different bodies, by one single weight placed at different distances from the prop or centre of motion D (fig. 7.). For the shorter arm DG is of such a weight as exactly to counterpoise the longer arm DX. If this arm is divided into as many equal parts as it will contain, each equal to GD, the single weight P (which we may suppose to be one pound) will serve for weighing any thing as heavy as itself, or as many times heavier as there are divisions in the arm DX, or any quantity between its own weight and that quantity. As for example, if P is one pound, and placed at the first division 1 in the arm DX, it will balance one pound in the scale at W; if it is removed to the second division at 2, it will balance two pounds in the scale; if to the third three pounds; and so on to the end of the arm DX. If any of these integral divisions is subdivided into as many equal parts as a pound contains ounces, and the weight P is placed at any of these subdivisions, so as to counterpoise what is in the scale, the pounds and odd ounces therein will by that means be ascertained.

The wheel and axle is a machine much used, and is made in a variety of forms. It consists of a wheel with an axle fixed to it, so as to turn round with it; the power being applied at the circumference of the wheel, and the weight to be raised is fastened to a rope which coils round the axle.

AB (fig. 9.) is a wheel and CD an axle fixed to it, and which moves round with it. If the rope which goes round the wheel is pulled, and the wheel turned once round, it is evident that as much rope will be drawn off as the circumference of the wheel; but while the wheel turns once round, the axle turns once round; and consequently

the rope by which the weight is suspended, will wind ounce round the axis, and the weight will be raised through a space equal to the circumference of the axis.

The velocity of the power, therefore, will be to that of the weight, as the circumference of the wheel to that of the axis.

That the power and the weight may be in equilibrio, the power must be to the weight as the circumference of the wheel to that of the axis.

It is proved by geometry that the circumferences of different circles bear the same proportion to each other as their respective diameters do; consequently the power is to the weight, as the diameter also of the axis to that of the wheel.

Thus, suppose the diameter of the wheel to be eight inches, and the diameter of the axis to be one inch; then one ounce acting as the power P, will balance eight ounces as a weight W; and a small additional force will cause the wheel to turn with its axis, and raise the weight; and for every inch which the weight rises, the power will fall eight inches.

The wheel and axis may be considered as a kind of perpetual lever, of which the fulcrum is the centre of the axis, and the long and short arms are the diameter of the wheel and the diameter of the axis. See fig. 10.

From this it is evident, that the larger the wheel, and the smaller the axis, the stronger is the power of this machine; but then the weight must rise slower in proportion.

A capstan is a cylinder of wood, with holes in it, into which are put bars, or levers, to turn it round; these are like the spokes of a wheel without the rim. Sometimes the axis is turned by a winch fastened to it, which in this respect serves for a wheel; and is more powerful in proportion to the largeness of the circle it describes, compared with the diameter of the axle.

When the parts of the axis differ in thickness, and weights are suspended at the different parts, they may be sustained by one and the same power applied to the circumference of the wheel; provided the product arising from the multiplication of the power into the diameter of the wheel, is equal to the sum of the products arising from the multiplication of the several weights into the diameters of those parts of the axis from which they are suspended.

In considering the theory of the wheel and axle, we have supposed the rope that goes round the axle to have no sensible thickness; but as in practice this cannot be the case, if it is a thick rope, or if there are several folds of it round the axis, you must measure to the middle of the outside rope, to obtain the diameter of the axis; for the distance of the weight from the centre is increased by the coiling of the rape.

If teeth are cut in the circumference of a wheel, and if they work in the teeth of another wheel of the same size, as fig. 11, it is evident that both the wheels will revolve in the same time; and the weight appended to the axle of the wheel B, will be raised in the same time as if the axle had been fixed to the wheel A. But if the teeth of the second wheel are made to work in teeth made in the axle of the first, as at fig. 12, as every part of the circumference of the second wheel is applied successively to the circumference of the axle of the first, and as the former is much greater than the latter, it is evident that the first wheel must go round as many times more than the second, as the circumference of the second wheel exceeds that of the first axle.

In order to a balance here, the power must be to the weight, as the product of the circumferences, or diameters of the two axles multiplied together, is to the circumferences or diameters of the two wheels.

This will become sufficiently clear, if it is considered as a compound lever, which was explained above. Instead of a combination of two wheels, three or four wheels may work in each other, or in any number; and by thus increasing the number of wheels, or by proportioning the wheels to the axis, any degree of power may be acquired.

To this sort of engine belong all cranes for raising great weights; and in this case the wheel may have cogs all round it, instead of handles; and a small lanthorn, or trundle, may be made to work in the cogs, and be turned by a winch, which will make the power of the engine to exceed the power of the man who works it, as much as the number of revolutions of the winch exceeds those of the axle CD, fig. 9, when multiplied by the excess of the length of the winch above the length of the semidiameter of the axle added to the semidiameter or half-thickness of the rope K, by which the weight is drawn up. Thus, suppose the diameter of the rope and axle taken together to be 13 inches, and consequently half their diameter to be $6\frac{1}{2}$ inches, so that the weight W will hang at $6\frac{1}{2}$ inches perpendicular distance from below the centre of the axle. Now, let us suppose the wheel AB, which is fixed on the axle, to have 80 cogs, and to be turned by means of a winch $6\frac{1}{2}$ inches long, fixed on the axle of a trundle of eight staves, or rounds, working in the cogs of the wheel; here it is plain, that the winch and trundle would make ten revolutions for one of the wheel AB, and its axis CD, on which the rope K winds in raising the weight W; and the winch being no longer than the sum of the semidiameters of the great axle and rope, the trundle could have no more power on the wheel than a man could have by pulling it round by the edge, because the winch would have no greater velocity than the edge of the wheel has, which we here suppose to be ten times as great as the velocity of the rising weight; so that, in this case, the power gained would be as 10 is to 1. But if the length of the winch is 13 inches, the power gained will be as 20 to 1; if $19\frac{1}{2}$ inches (which is long enough for any man to work by), the power gained will be as 30 to 1; that is, a man could raise 30 times as much by such an engine, as he could do by his natural strength without it, because the velocity of the handle of the winch would be 30 times as great as the velocity of the rising weight; the absolute force of any engine being in the proportion of the velocity of the power, to the velocity of the weight raised by it. But then, just as much power or advantage as is gained by the engine, so much time is lost in working it, which is common in all mechanical cases whatever.

In this sort of machines it is requisite to have a ratchet wheel on the end of the axle C, with a catch to fall into its teeth; which will at any time support the weight, and keep it from descending, if the person who turns the handle should, through inadvertence or carelessness, quit

his hold while the weight is rising. By this means, the danger is prevented which might otherwise happen by the running down of the weight when left at liberty.

The *pulley* is a small wheel turning on an axis, with a drawing-rope passing over it: the small wheel is usually called a sheeve, and is so fixed in a box, or block, as to be moveable round a pin passing through its centre.

Pulleys are of two kinds:—1. Fixed, which do not move out of their places: 2. Moveable, which rise and fall with the weight.

When a pulley is fixed, as fig. 13, two equal weights suspended to the ends of a rope passing over it, will balance each other; for they stretch the rope equally, and if either of them is pulled down through any given space, the other will rise through an equal space in the same time; and consequently, as the velocities of both are equal, they must balance each other. This kind of pulley, therefore, gives no mechanical advantage; so that you can raise no greater weight by it than you could do by your natural strength. Its use consists in changing the direction of the power, and sometimes enabling it to be applied with more convenience. By it, a man may raise a weight to any point, without moving from the place he is in; whereas, otherwise, he would have been obliged to ascend with the weight: it also enables several men together to apply their strength to the weight by means of the rope.

The moveable pulley represented at A (fig. 14), is fixed to the weight W, and rises and falls with it. In comparing this to a lever, the fulcrum must be considered as at A; the weight acts upon the centre, and the power is applied at the extremity of the lever D. The power, therefore, being twice as far from the fulcrum as the weight is, the proportion between the power and weight, in order to balance each other, must be as 1 to 2. Whence it appears, that the use of this pulley doubles the power, and that a man may raise twice as much by it as by his strength alone. Or it may be considered in this way: Every moveable pulley hangs by two ropes equally stretched, and which must, consequently, bear equal parts of the weight; but the rope AB being made fast at B, half the weight is sustained by it; and the other part of the rope, to which the power is applied, has but half the weight to support; consequently the advantage gained by this pulley is as 2 to 1.

When the upper and fixed block contains two pulleys, which only turn upon their axes, and the lower moveable block contains also two, which not only turn on their axis, but rise with the weight W (fig. 15), the advantage gained is as 4 to 1. For each lower pulley will be acted upon by an equal part of the weight; and because in each pulley that moves with the weight, a double increase of power is gained, the force by which F may be sustained, will be equal to half the weight divided by the number of lower pulleys; that is, as twice the number of lower pulleys is to 1, so is the weight suspended to the power.

But if the extremity C (fig. 16) is fixed to the lower block, it will sustain half as much as a pulley; consequently here the rule will be, as twice the number of pulleys adding unity is to 1, so is the weight to the power.

These rules hold good, whatever may be the number of pulleys in the blocks.

If, instead of one rope going round all the pulleys, the rope belonging to each pulley is made fast at top, as in fig. 17, a different proportion between the power and the weight will take place. Here it is evident, that each pulley doubles the power: thus, if there are two pulleys, the power will sustain four times the weight.

Fig. 8, is the concentric pulley, invented by Mr. James White. O, R, are two brass blocks, in which grooves are cut; and round these a cord is passed, by which means they answer the purpose of so many distinct pulleys. The advantage gained is found by doubling the number of grooves in the lower block.

It is common to place all the pulleys in each block on the same pin, by the aide of each other, as in fig. 18; but the advantage, and rule for the power, are the same here as in figs. 15 and 16.

A pair of blocks with the rope fastened round it, is commonly called a tackle.

[The above is the doctrine usually given in books to illustrate the theory of the mechanical power of the moveable block; but for the following ingenious and more simple method, we are in some measure indebted to a gentleman at Cambridge, England.

We call it *the moveable block*, because it is entirely erroneous to consider a pulley a mechanical power; as no advantage whatsoever is gained by the pulley itself, excepting that which merely arises from the abatement of the friction.

Axiom. The tension of the same string is the same though continued over any number of pullies.

Cor. In a fixed pulley, the power and the weight are equal; for the tension at B (fig. 13.) is equal to that at C.

It is evident, therefore, that the sole use of the fixed pulley is to change the direction of the moving power. But it is just the reverse in the moveable pulley or block, which adds to the moment of the power, but causes no change in its direction.

A weight is supported by a power with the assistance of a moveable block containing one pulley: To find the ratio between the power and the weight.

Let the power or tension of the string C (fig. 14) $= m$, the tension of F and E is each equal to m, but the strings F and E are spent in supporting the string for the weight, which therefore $= 2m$.

Consequently the power : weight $:: m : 2m :: 1 : 2$.

Cor. If the number of pullies in the moveable block $= n$, it may be found by a similar process that $P : W :: 1 : 2n$. Therefore, if the same string be continued over two blocks of pullies (figs. 15, 16, 18,) P will be to W as unity to the number of strings at the moveable block. The strings which support the moveable block, support each an equal share of the weight, and the power is equal to the tension of those strings.

Let the power (fig. 17) $= m$: to calculate the tension of the strings A, B, C, &c.

$$\text{The tension of} \begin{cases} A = m \\ B = m \\ C = m \\ D = 2m \\ E = 2m \\ F = 4m \\ G = 4m \\ H = 8m \end{cases}$$

Therefore $P : W :: m : 8m :: 1 : 8$.

Cor. In a combination of pullies of this kind, if the number of pullies $= n$, $P : W :: 1 : 2^n$. That is, as unity to that power of 2 whose index is the number of moveable blocks. We have generally observed, however, that mechanics, in the arrangement of tackle, especially on board of our vessels, prefer constructions different from those which have been noticed: and as these constructions have not, as far as we know, been exhibited in any treatise on the mechanical powers, we shall insert them, with the separate statement of the power gained.

In fig. 33, the tension of the strings 1, 1, is each equal to 1 and the tension of $2 = 2$; therefore the power : weight $:: 1 : 1 + 2 = 3$. The universal rule in this construction is, if $n =$ number of pullies both fixed and moveable, $P : W :: 1 : 2^n - 1$.

In fig. 30, the tension of the strings is represented by the figures, therefore $P : W :: 1 : 1 + 2 + 1 + 1 = 5$.

As in some cases it becomes desirable to be enabled with the same tackle to hoist heavy articles *with ease*, and also light ones *without loss of time*, a very advantageous method is adopted by means of a rope called a runner; which, when lighter goods are hoisted from the holds of vessels, is hooked to a staple on deck near the hatchway, and when heavy packages are to be raised, is hooked to *them*: as in fig. 31; if W be light, the runner A is attached to the staple C, and the power $= 3$; but if it be heavy, it is hooked with B, to W, and the power $= 7$. Whereas it is evident, that if A were always attached to B, the power 7, being greater than necessary to hoist smaller packages, a loss of time would follow; and if A were always hooked to the staple C, the power 3 would be less than efficient to raise heavy articles.

In fig. 32 the same effects follow, and by that construction the powers vary from 4 to 9.

It may be observed, generally, that in all constructions of pullies, the power is to the weight as the velocity of the weight is to the velocity of the power; or, which is the same thing, the space passed through by each in any given time. [*p*]

The *inclined plane*. This mechanical power is of very great use in rolling up heavy bodies, such as casks, wheelbarrows, &c. It is formed by placing boards, or earth, in a sloping direction.

The force wherewith a body descends upon an inclined plane, is to the force of its absolute gravity, by which it would descend perpendicularly in free space, as the height of the plane is to its length. For suppose the plane AB (fig. 12) to be parallel to the horizon, the cylinder C will keep at rest on any part of the plane where it is laid. If the plane is placed perpendicularly, as AB, fig. 20, the cylinder C will descend with its whole force of gravity, because the plane contributes nothing to its support or hindrance; and therefore it would require a power equal to its whole weight to keep it from descending.

Let AB (fig. 21) be a plane parallel to the horizon, and AD a plane inclined to it; and suppose the whole length AD to be three times as great as the perpendicular DB. In this case the cylinder E will be supported upon the plane DA, and kept from rolling, by a power equal to a third part of the weight of the cylinder; therefore a weight may be rolled up this inclined plane, by a third part of the power which would be sufficient to draw it up by the side of an upright wall.

It must also be evident, that the less the angle of elevation, or the gentler the ascent is, the greater will be the weight which a given power can draw up; for the steeper the inclined plane is, the less does it support of the weight; and the greater the tendency which the weight has to roll, consequently the more difficult for the power to support it: the advantage gained by this mechanical power, therefore, is as great as its length exceeds its perpendicular height.

To the inclined plane may be reduced all hatchets, chisels, and other edge-tools.

The *wedge* is the fifth mechanical power or machine: it may be considered as two equally inclined planes, joined together at their bases; then DG (fig. 22) is the whole thickness of the wedge at its back ABGD, where the power is applied; EF is the depth or height of the wedge, BF the length of one of its sides; and OF is its sharp edge, which is entered into the wood intended to be split, by the force of a hammer or mallet striking perpendicularly on its back. Thus, AB (fig. 23) is a wedge driven into the cleft CED of the wood FG.

When the wood does not cleave at any distance before the wedge, there will be an equilibrium between the power impelling the wedge downward, and the resistance of the wood acting against the two sides of the wedge, when the power is to the resistance as half the thickness of the wedge at its back is to the length of either of its sides; because the resistance then acts perpendicular to the side of the wedge. But when the resistance on each sides acts parallel to the back, the power that balances the resistances on both sides will be, as the length of the whole back of the wedge is to double its perpendicular height.

When the wood cleaves at any distance before the wedge (as it generally does), the power impelling the wedge will not be to the resistance of the wood as the length on the back of the wedge is to the length of both its sides, but as half the length of the back is to the length of either side of the cleft, estimated from the top or acting part of the wedge. For, if we suppose the wedge to be lengthened down from the top CE, to the bottom of the cleft at D, the same proportion will hold; namely, that the power will be to the resistance as half the length of the back of the wedge is to the length of either of its sides: or, which amounts to the same thing, as the whole length of the back is to the length of both the sides.

The wedge is a very great mechanical power, since not only wood, but even rocks, can be split by it; which it would be impossible to effect by the lever, wheel and axle, or pulley; for the force of the blow, or stroke, shakes the cohering parts, and thereby makes them separate more easily.

The *screw* (fig. 24.) is the sixth and last mechanical power, but cannot properly be called a simple machine, because it is never used without the application of a lever or winch to assist in turning it; and then it becomes a compound engine of a very great force, either in pressing the parts of bodies closer together, or in raising great weights. It may be conceived to be made by cutting a piece of paper, ABC (fig. 25), into the form of an incli-

ned pane, or half-wedge; and then wrapping it round a cylinder (fig. 26), the edge of the paper AC will form a spiral line round the cylinder, which will give the thread of the screw. It being evident that the winch must turn the cylinder once round, before the weight of resistance can be moved from one spiral winding to another; therefore, as much as the circumference of a circle described by the handle of the winch is greater than the interval or distance between the spirals, so much is the force of the screw. Thus, supposing the distance of the spirals to be half an inch, and the length of the winch twelve inches, the circle described by the handle of the winch where the power acts will be 76 inches nearly, or about 152 half inches, and consequently 152 times as great as the distance between the spirals: and therefore a power at the handle, whose intensity is equal to no more than a single pound, will balance 152 pounds acting against the screw; and as much additional force as is sufficient to overcome the friction, will raise the 152 pounds; and the velocity of the power will be to the velocity of the weight, as 152 to 1. Hence it appears, that the longer the winch is, and the nearer the spirals are to one another, so much the greater is the force of the screw.

A machine for showing the force or power of the screw may be contrived in the following manner:—Let the wheel C have a screw (fig. 24) on its axis, working in the teeth of the wheel D, which suppose to be 48 in number. It is plain, that for every time the wheel C and screw are turned round by the winch A, the wheel D will be moved one tooth by the screw; and therefore, in 48 revolutions of the winch, the wheel D will be turned once round. Then, if the circumference of a circle, described by the handle of the winch A, is equal to the circumference of a groove round the wheel D, the velocity of the handle will be 48 times as great as the velocity of any given point in the groove. Consequently, if a line G goes round the groove, and has a weight of 48 pounds hung to it, a power equal to 1 pound at the handle will balance and support the weight. To prove this by experiment, let the circumferences of the grooves of the wheels C and D be equal to one another; and then if a weight H, of 1 pound, is suspended by a line going round the groove of the wheel C, it will balance a weight of 48 pounds hanging by the line G; and a small addition to the weight H will cause it to descend, and so raise up the other weight.

If a line G, instead of going round the groove of the wheel D, goes round its axle 1, the power of the machine will be as much increased as the circumference of the groove exceeds the circumference of the axle; which supposing to be six times, then one pound at H will balance six times 48, or 288 pounds, hung to the line on the axle: and hence the power or advantage of this machine will be as 288 to 1. That is, a man who by his natural strength could lift a hundred weight, will be able to raise 288 cwts. by this engine. If a system of pulleys was applied to the cord H, the power would be increased to an amazing degree.

When a screw acts in a wheel in this manner, it is called an endless screw.

When it is not employed in turning a wheel, it consists of two parts: the first is called the male or outside screw; being cut in such a manner, as to have a prominent part going round the cylinder in a spiral manner, which prominent part is called the thread of the screw; the other part, which is called the female, or inside screw, is a solid body, containing a hollow cylinder, whose concave surface is cut in the same manner as the convex surface of the male screw, so that the prominent parts of the one may fit the concave parts of the other.

A very considerable degree of friction always acts against the power in a screw; but this is fully compensated by other advantages; for on this account the screw continues to sustain a weight, even after the power is removed, or ceases to act, and presses upon the body against which it is driven. Hence the screw will sustain very great weights: insomuch that several screws, properly applied, would support a large building, whilst the foundation was mending, or renewed.

OF COMPOUND MACHINES.

Though it is evident from the principles delivered above, that any of the mechanical powers is capable of overcoming the greatest possible resistance, in theory; yet, in practice, if used singly for producing very great effects, they would be frequently so unwieldy and unmanageable, as to render it impossible to apply them. For this reason, it is generally found more advantageous to combine them together; by which means the power is more easily applied, and many other advantages are obtained. In all machines, simple as well as compound, what is gained in power is lost in time. Suppose that a man, by a fixed pulley, raises a beam to the top of a house in two minutes, it is clear that he will be able to raise six beams in twelve minutes; but by means of a tackle, with three lower pulleys, he will raise the six beams at once, with the same ease as he before raised one; but then he will be six times as long about it, that is, twelve minutes: thus the work is performed in the same time, whether the mechanical power is used or not. But the convenience gained by the power is very great; for if the six beams are joined in one, they may be raised by the tackle, though it would be impossible to move them by the unassisted strength of one man.

Consequently, if by any power you are able to raise a pound with a given velocity, it will be impossible, by the help of any machine, to raise two pounds with the same velocity; yet, by the assistance of a machine, you may raise two pounds with half that velocity, or even one thousand with the thousandth part of that velocity; but still there is no greater quantity of motion produced, when a thousand pounds are moved, than when one pound is moved; the thousand pounds moving proportionally slower.

No real gain of force is, therefore, obtained by mechanical contrivances; on the contrary, from friction, and other causes, force is always lost; but by machines we are able to give a more convenient direction to the moving power, and to apply its action at some distance from the body to be moved, which is a circumstance of infinite importance. By machines also, we can so modify the energy of the moving power, as to obtain effects which it could not produce without this modification.

In machines composed of several of the mechanical powers, the power will be to the weight, when they are in equilibrio, in a proportion formed by the multiplication of the several proportions which the power bears to the

was the drachma, or eighth part of an ounce, of which Mr. Pinkerton describes the medial value to be ninepence sterling: the didrachm, tridrachm, and tetradrachm, explain themselves, except the tetradrachm of the Æginean standard, which was valued at five shillings. This last was the largest form of the Greek silver coins. The silver divisions of drachma were the tetrobolion, the hemidrachm or tribolion, the diobolion, the obolus, the hemiobolion, the tetrabolion, and dichalcos; the first of the value of sixpence, the last of a farthing and a half. Of the distinct names by which many of these coins were called among the different states, our intelligence is partial; nor are such names of consequence.

The next Greek coinage, in point of antiquity, is that of copper, which is said not to have been introduced till four hundred and four years before the christian æra. The first copper coin of Greece was the chalcos, of which two went to the quarter of the silver obulus. In days of poverty, however, even this was divided by different states into different portions, which were called λεπτα, or little coins. The lepton, dilepton, and tetralepton, were the divisions of the chalcos, the smaller of which, from their perishable size, are very rare. Such were the brass coins of Greece previous to the subjection of that country to the Roman empire.

The earliest of the gold coins of Greece are those of Philip of Macedon, although they were struck in Sicily considerably earlier. Philip, having conquered the city Crenides, on the confines of Thrace, found gold-mines in its neighbourhood, formerly ill explored, and of small produce. From this gold he first struck the coins called Philippi, because of his portrait which appears on them. The Philippi it should seem were didrachms, the form most universal in the ancient coinages of gold; and at their first appearance went for 20 silver drachmæ, but in latter times for 25 Greek drachmæ, or Roman denarii. The Philippus was also called Χρυσος. There were likewise the ημιχρυσος and the τεταρτοχρυσος, with gold coins of Cyrene, which could not have gone for more than two drachmas of silver. There were also the Δι χρυσος and the Τετραςηρ, or quadruple χρυσος; the former worth about two, and the latter worth about four pounds of our money.

The original value of the Roman coins is a subject still more intricate and extensive. As in Greece, the first estimation of their money was by weight; though copper, not silver, was the first medium of coinage. The first Roman coinage, according to Mr. Pinkerton, was in the reign of Servius Tullus, about the year 460 before the common æra, and was confined to the as or æs libralis, or piece of brass only, which was stamped with the two faced head of Janus on the one side, and the prow of a ship on the other; though Mr. Pinkerton afterward thinks it probable that the very first Roman ases of Tullus had the figure of a bull, ram, or other species of cattle. However this may be, parts of the as were very early given in proportion of weight and value: such were the semis or half, the triens, the quadrans, the sextans, and the uncia. After a certain period, the as, though still called libra, fell to two ounces; and as it fell in weight, larger denominations were coined. Such were the bissus or dupondius, the tressis, the quadrussis, and even the decussis, or piece of ten ases in copper.

When the Romans began, by intercourse with Greece, to imbibe the arts of elegance, a variety of types appeared upon the parts of the as, and at length upon the as itself; though these, it is believed, are not seen till near the time of Sylla. Dupondii, or double ases, were also coined in the later period of the commonwealth, as in the former; together with the sestercii æerei, which came in place of the quadrusses. It must also be observed that the Romans, in some instances, accommodated their coins to the country in which their army was stationed; so that it is from the coins struck at Rome only that the coinage can be adjusted.

The largest of the imperial brass coins, according to our author, was the sestercius, worth about twopence English; no sensible diminution of which from its first weight of an ounce took place till the reign of Alexander Severus, when it lost upwards of a sixth. In the time of the Philippi, it was still more reduced; and under Trajanus Decius it had lost near a half. He was the first prince who seems to have coined double sestercii, or quinarii of brass, for such are the common medallions inscribed FELICITAS SAECVLI, or VICTORIA AVG., which just weigh double his sestercii, and little more than the sestercii of the early emperors. From Trebonianus Gallus down to Gallienus, when what is called the first brass ceases, the setercius does not weigh above one-third of an ounce; any larger are double sestercii, or medallions struck upon uncommon occasions. After Gallienus, the sestercius totally vanishes. Under Valerian and Gallienus, a new coinage appears of what were called denarii æris, or Philippei æria of copper washed with silver. In the reign of Diocletian, the follis supplied the place of the sestercius; and soon after we find the denarius æreus dropped for ever. Such was the progress of the largest form of the imperial brass coin of Rome.

The dupondius, being half the sestercius, was the next in value. Prior to Augustus, it seems to have been commonly struck in copper; though after his time it was struck in yellow brass. It kept pace with the sestercius in all its stages.

The imperial as or assarium is the next coin. It began to be called assarium as soon as its size was reduced to half an ounce, and, like the dupondius, diminished gradually in its form, till at the end of Gallienus's reign it became what is called small brass. The parts of the as, says Mr. Pinkerton, in the imperial times, are, generally speaking, very rare. However, of Nero, there are the semis, triens, quadrans, sextans, and uncia, being all the parts; and of Domitian there are the same.

From Pertinax down to Gallienus, there is no small brass save of Trajanus Decius. With Gallienus it becomes extremely common. Toward the end of his reign the assaria were diminishing to a still less size. Farther we shall not trace this branch of the coinage.

The silver coinage of Rome is supposed first to have taken place about 266 years before the christian æra. The most ancient denarii are those on which no inscription, save the word ROMA, appears: and at that time the denarius seems to have gone for ten ases: though it was afterward raised to sixteen, till the time of Gallienus. Under Caracalla, when the silver coinage was debased, denarii were struck of two sizes; the larger bearing an increase of value by a third. Both, however, lessened by degrees till after Gordian III. when the smaller total-

ly vanished, and the larger alone remained. The latter, in the time of Gallienus, was the sole denarius of silver, and probably gave rise to the denarii æreí, which have been already mentioned. Such was the silver coinage till the time of Constantine the First, when the milliarensis was introduced, weighing about 70 grains, and answering in worth to our shilling. The denarii or argentei were, however, still coined, and were the money most common in currency.

Of the smaller silver coins of Rome, two only remain to be mentioned, the quinarii or pieces of five ases, and the sestercii of silver, which seem to have been coined down to Augustus.

Gold, we are informed by Pliny, was first coined at Rome in the 204th year before the present æra; and his account of the diminution in weight which marked the progress of its coinage, is singularly coroborated by such coins as have come down to us. The scruple, he says, went for 20 sesterces. "It was afterward thought proper to coin 40 pieces out of the pound of gold. And our princes have by degrees diminished their weight to 45 in the pound." Till Sylla's time, the aureus continued at 30 denarii; it afterwards fell to 20; though both under Claudius and Severus we find it at 25. Constantine the First, instead of the aureus, gave the solidus, of six in the ounce of gold, one of which answered to 14 of the miliarenses. The solidus continued of the very same standard to the close of the Byzantine empire.

Of the potraits which are to be found on coins, those of the kings of Macedon have the first rank, as their coins have the greatest antiquity of any yet discovered on which portraits are found. Alexander I. begins the series, who reigned 501 years before the christian æra. Then follow the kings and queens of Sicily, Caria, Cyprus, Pontus, Egypt, Syria, Thrace, Bithynia, &c. extending in series from the time of Alexander the Great to the birth of Christ, comprising a period of about 330 years. In this class are placed the beautiful coins of the Seleucidæ. The last series of ancient kings goes down to the fourth century, including those of Mauritania and Juda; and finishing the series of the portraits of kings found on medals struck with Grecian characters.

The Roman emperors present a most distinct series from Julius to a later period than the destruction of Rome by the Goths.

The kings, upon Greek coins, have generally the diadem, without any other ornament, usually with a side face, and almost always in very high relief; though several, particularly the beautiful gold coin of Ptolemy Philadelphus, others of Antony and Cleopatra, &c. have more portraits than one upon them. The chief ornament of the portraits is the diadem or vitta. The radiated crown, a mark of deification, on the posthumous coins of Augustus, was, in a little more than a century after, put upon most of the emperors' heads in their several medals. The crown of laurel is continually seen: and Agrippa appears not only with the rostral but the mural crown. The successors of Alexander assumed, by way of distinction, different symbols of deity on the busts of their medals. A few instances also occur, among the Roman coins, of the helmet.

The reverses of medals, both among the Greeks and Romans, were of infinite variety. They contain figures of deities at whole length with their attributes and symbols; public buildings and diversions; allegorical representations; ceremonies; historical and private events; figures of ancient statues; subjects of natural history; magistracies, &c. The reverses of the Roman coins have more of art and design than the Greek, though the latter have more exquisite relief. In the very ancient coins no reverse is found, and of the ancient Greek reverses some are in intaglio. The figures of deities and personifications on the Roman coins, are commonly attended with the names: as, the figure of Virtue with VIRTVS AVGVSTI: but on the reverse of the Greek coins the figure is only accompanied by some certain symbol; as Ceres with her wheaten garland, Mars with his armour, or Mercury with his caduceus. The anchor on Seleucian coins is the mark of Antioch; the owl, of Athens; the labyrinth, of Crete; the horse, of Thessaly; and so on.

Of the legends, the early Greek coins usually contain the name or the initials of the city they belong to; or the name, the first character of it, or the monogram, of the prince. The earliest coins of Athens have only ΑΘΕ, money of Athens; ΣΥ, of Sybasis; ΜΑΣ, of Massilia. ΣΥRΑΚΟΥΣΙΩΝ occurs at full length, as well as ΦΙΛΙΠΠΟΣ for Philip of Macedon. And though in aftertimes the names of princes were accompanied by modest adjuncts, there were others that were not a little proud. Of the former were ΔΙΚΑΙΟΥ ΕΥΣΕΒΟΥΕ ΦΙΛΕΛΛΗΝΟΣ; of the latter, ΘΕΟΠΑΤΟΡΟΣ ΒΑΣΙΛΕΩΣ ΒΑΣΙΛΕΩΝ, &c.

After the Roman empire had swallowed up the Grecian, the legends on Greek coins became as remarkable for length as they had been before for brevity. The Greek imperial coins have a great variety in their legends. Nor are many of the reverses wanting in adulation. The legends of the Roman imperial coins are still more deservedly celebrated for their beautiful simplicity. IVDEA CAPTA and ASIA SUBACTA are sufficient instances.

Of the pieces produced by the ancient mints, there were some of a size which showed them evidently to have been intended for something else than circulation. Medallions were occasionally presented by the emperor to his friends; and sometimes by the mint-master to the emperor as specimens of workmanship. These are usually known by their weight, which is far greater than that of the acknowledged money. Both the Greek and Roman medallions appear to have been principally struck in the imperial periods. Till the time of Hadrian they are rare. For a more full account of them, we refer to the work of Mr. Pinkerton.

To dwell longer on the various types either of the Grecian or the Roman coins, would be surperfluous. Their curiosity and elegance are infinite. The regal coins of Greece are interesting from their portraits; the coins of cities, from their importance to geography. On the consular coins of Rome, the names and titles of the consuls do not appear till toward the close of the series: the brass consular coins are uninteresting. The imperial brass is of three sizes, large, middle, and small; the first forming a series of the greatest beauty. The imperial silver coins are numerous; the gold, of wonderful perfection. For the different abbreviations which

occur both upon the Greek and Roman coins, we shall refer to the Tables selected by Mr. Pinkerton, as it would be impossible, in so concise a work as this, to give every information which the collector might require. The best works upon the Greek and Roman coins are probably these: Froelich's Notitia Elementaris; Neuman's Populi and Reges inediti; the Works of Pellerin; the Nummi populorum et urbium Magnæ Græciæ, by Dr. Combe; Havercamp on the Consular Coins; and the Roman Imperial, by Valliant, edition 1745, by Valdini, with the Supplement by Kehl.

Of the early British coins, previous to the arrival of the Romans, we know but little. They were probably like the ancient Gaulish, rudely ornamented, and without inscriptions. Those which we usually call British, were evidently the work of Roman moneyers. Those with CVNO on one side, and CAMV on the other, are usually ascribed to Cunobelin, the king of the Trinobantes. There is also one which has a bull on the obverse, with V. E. R. V. L. A. M. I. O. for the legend, apparently struck at Verulam. The meaning of *taseia*, which is common both to the Gallic and the British coins, wants explanation.

Of the coins of the Saxon heptarchy, there are but two descriptions: the sceatta, or penny, and the styca; the latter of which seems to have been principally confined to the kingdom of Northumbria. Of the coins of the heptarchic princes, the series is very far from regular; and of one or two princes unique specimens only are known. Of the chief monarchs, Ethelbald and Edmund Ironside are the only two who break the series. Of their coinage we have no specimens. The obverses of all these bear merely the resemblance of a human bust; though the reverses are occasionally interesting. The inscriptions also are sometimes peculiar, and we have a few specimens in the ninth century of archiepiscopal coinage. The best guide to the collector of Anglo-Saxon coins will be found in the plates of Dr. Hickes's "Thesaurus;" their rarity and value may be learnt from the Essay we have so often quoted.

The two first kings after the Conquest coined only pennies, the types of which are different, though in point of weight and goodness they agree with the pennies of the Saxons: their weight was usually 22 grains and a half. The obverse represents sometimes the full, and sometimes the side face of the sovereign, with the name of the mint-master and town of mintage on the reverse. To pennies, Henry the First added halfpennies, though none of them have reached us. King Stephen's pennies were of the same value as those of his predecessors. There are also some extant, which have the name of Eustace on them. Stephen's son; and one occurs with the head and title of Henry bishop of Winchester, the king's base brother. Those of Stephen which have the banner are the rarest. The pennies of Henry the Second are also scarce; of Richard the First we have only the French penny; and of John no money but what was coined in Ireland; though of the last there are not only pennies but halfpennies and farthings. The first coinage of Henry the Third had only on the obverse HENRICVS REX, and his pennies till within these 30 years were usually ascribed to Henry the Second. After his 32d year, we find III or TERCI added to the title. The pennies, halfpennies, and farthings of Edward the First are all common. Such pennies as have EDW. R. ANGL. DNS. HYB upon the obverse, are usually ascribed to Edward the First; those with EDWA. or EDWAR. to Edward the Second; and those with EDWARD or EDWARDVS to Edward the Third. This, however, is but conjecture. In the 18th of Edward the Third, the penny was brought down to 20 grains; and in his 27th year, we find groats and half-groats coined, in which the king's head was surrounded by a sort of double treasure. In the reign of Edward the Fourth, having previously sunk to 15, the penny fell to 12 grains. In Edward the Sixth's time, it was reduced to eight, and in Elizabeth's to little more than seven. Of the groats, Richard the Third is very rare. In 1503, Henry the Seventh coined the shilling or testoon: it resembled the groat, but was larger, and weighed no less than 144 troy-grains. The crown of silver was first struck by Henry VIII. and the half-crown sixpence, and threepence, by Edward the Sixth. Elizabeth, in 1558, coined three-halfpenny, and in 1561, three farthing pieces; but they were disused in 1582. Henry the Eighth was the first of our princes who debased the coinage; and in the earlier part of Edward the Sixth's reign, the practice was continued: but from the 43d of Elizabeth, 1601, the denomination, weight, and fineness of English silver, have remained the same. From 1561 to 1568, the money of Elizabeth was coined in a better taste, by means of a mill and screw, but the artist of this money being hanged for counterfeiting coins, the hammering system was again recurred to. Till the time of Charles the second, we have little more of the milled money.

The design of a gold coinage appears to have been first formed by Henry the Third, the most particular account of which is to be found in lord Liverpool's Letter to the King. The piece ordered to be current was called a gold penny; but being of too great value for general circulation, it was in two or three years called in, and now but three specimens remain. In itself, the gold penny is a beautiful specimen of the coinage of the time. The obverse is much in the manner of the king's great seal, and the inscription Henricus Rex III.; on the reverse, the mint-master's name and place. The three known are all of different types: one reads LVND, another LVNDE, and the third LVNDEN. But it is from Edward the Third that the series of our gold coins commences. In 1344, he struck the florin, half, and quarter florin. The florin was current for six shillings, but was the same year succeeded by the noble, the value of which was half a mark. Henry the Fifth diminished the value of the noble; Henry the Sixth restored it to its size, and gave it the name of ryal; while Edward the Fourth, in 1465, supplanted it with the angel. Henry the Eighth, in 1523, added the gold crown and half crown at their present value: the sovereign of 22*s.* 6*d.*; the ryal at 11*s.* 3*d.*; the angel at 7*s.* 6*d.*; and the noble at its old value. In 1546, he coined sovereigns and half-sovereigns, the former to go at 20*s.* and the latter in proportion. Charles the Second, however, instead of the sovereign, introduced the guinea and half-guinea. George the Frst added the quarter-guinea. But though it was continued in the early part of the reign of his present majesty, the seven-shilling piece has been preferred.

The history of our copper coinage, the last in order of chronology, will be shorter. From the reign of Henry the Eighth till the close of queen Elizabeth's reign, the scarcity of silver farthings and halfpence gave rise to the introduction of tokens or pledges for money among tradesmen, many of which are undoubtedly alluded to in what has been said by Erasmus and other writers about leaden money. Elizabeth, it appears, would never hear of a copper coinage for the country: and though farthing tokens of copper were issued both by James and Charles the First, they were considered rather as pledges of government than legitimate money. The death of Charles the First put an effectual stop to their farther currency: and till 1672, the country again swarmed with town pieces and tradesmen's pledges; when, in the latter year, halfpence and farthings of copper were made public money, and the circulation of tokens forbidden. His present majesty has added two-penny pieces.

MEDEOLA, *climbing African asparagus*, a genus of the hexandria order, in the trigynia class of plants, and in the natural method ranking under the 11th order, sarmentaceæ. There is no calyx; the corolla is sexpartite and revoluted; the berry trispermous. Its characters are these: the flower has no empalement; it has six oblong oval petals, and six awl-shaped stamina terminated by incumbent summits; and three horned germina terminating the style; the germina afterward turn to a roundish trifid berry with three cells, each containing one heart-shaped seed. There are three species.

MEDICAGO, *snail-trefoil*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The legumen is compressed and screwed; the carina of the corolla luring down from the vexillum. There are eleven species. They are low trailing plants, adorned with small yellow flowers, succeeded by small round snail-shaped fruit, which are downy, and armed with a few short spines. They are all easily propagated by seeds. The M. sativa or lucern, has been latterly much recommended as a green fodder for cattle, and has been cultivated by some farmers with success.

MEDICINE, is the art of preserving health, and of curing or alleviating disease. It is the same science in its application to animal, as agriculture to vegetable, life.

Origin and progress of medicine. "Medicina nusquam non est." This art arises out of the natural, as others more gradually and indirectly originate from the artificial and adventitious, wants of mankind. The exact period, however, in which medicine began to be formally practised as an art, or separately cultivated as a profession, has by no means been accurately ascertained. All the accounts which have been transmitted on this subject from a date prior to the time of Hippocrates are either conjectural or fabulous. Hippocrates first effected a separation of medicine from philosophy and religion, and gave it the form of a distinct science: he has therefore been generally regarded by the moderns as the father of physic; and from his time the history of this science may be made with propriety to commence.

Hippocrates was a native of Greece. He was born in the island of Cos, and flourished about 400 years prior to the christian æra. Of his character as a physician, an estimate cannot, confessedly with much accuracy, be formed from his writings, or from those works which have been attributed to him, but which are generally regarded as in a great measure the inventions of his disciples and successors. "Hippocrates," says a modern author, "lived at too early a period to be acquainted with the collateral branches of science. He studied life and disease in the book of nature, and had the merit of an original observer." We do not, however, feel disposed with this author fully to acquit the "Coan sage of the many idle theories which have been imputed to him." It may well be conceived that he was influenced in his opinions on the cause of disease and on the nature of healing, if not by the splendid fictions of the Greek philosophy, by preconceived theory and vague conjecture. Indeed, the hypotheses contained in the reputed writings at least of Hippocrates, have been, with trivial modifications, the hypotheses of modern times; for in this author's pervading and presiding principle of nature, and in his attraction, depuration, decoction, and crisis of disease, may be traced the same mode of theorizing which has been adopted by later systematics.

The humoral pathology, and even the *vis naturæ medicatrix* of modern times, appear to be modifications or relics of Hippocratic reasoning.

The immedediate successors of Hippocrates began to direct their researches into the auxiliary departments of medicine; and among these, Praxagoras, Chrysippus, Hirophilus, and Erasistratus, particularly the two last, made no inconsiderable discoveries (when we consider the scantiness of their materials) respecting the structure and functions of the human frame. It was about this period, according to Celsus, that the science was divided into the three distinct branches of dietetical, pharmaceutical, and chirurgical medicine—"una quæ victu, altera quæ medicamentis, tertia quæ manu mederetur." Shortly after the time of Herophilus, the medical world became divided into the two sects of empirics and dogmatists: the one, rejecting the reasoning and deriding the practice of their predecessors, affected to disregard all authority but that of experience; the other, retaining their faith in the scholastic philosophy of the times, and their conviction of the utility of physiological knowledge in detecting the causes and regulating the treatment of disease. The empiric sect was founded by Serapion of Alexandria, about 287 years before Christ.

The next revolution of importance in the medical art was occasioned by the introduction of the European philosophy into the schools of medicine. This was effected by Asclepiades, who was succeeded by Themison, the founder of the methodic sect, the members of which were equally hostile to the dogmatists and empirics. They discarded what they considered the occult reasoning of the former, and substituted in the room of the laborious observations of the latter, indications of treatments deduced from the analogy of diseases, or the mutual resemblance they bear to each other, "nullius causæ notitiam quicquam ad curationes pertinere; satisque esse quædam communæ morborum intueri methodici contendunt." *Celsus.* The most celebrated of Themison's followers were Thessalus, who flourished under the emperor Nero, and Soranus, a native of Ephesus, who lived during the time of the emperors Trajan and Adrian.

We have now arrived at a very conspicuous æra in

the science of medicine. About the 131st year after Christ, in the reign of Adrian, lived the celebrated Galen, who was born at Pergamus. At this time the dogmatic, empiric, and methodic sects of physicians had each their advocates. The methodics, however, were held in greatest estimation. Galen undertook the reformation of medicine, and affected to restore the Hippocratic philosophy and practice. Instead, however, of abiding by the doctrines of his master, his systems were almost entirely of his own invention. "Philosophy and science had now made some advances; and from those sources Galen introduced many corruptions into medicine." Like Hippocrates, he supposed the existence of four humours, from the predominancy or deficiency of one or other of which the varieties of constitutions, and likewise the complexion and nature of disease, were conjectured to originate. These humours are, in the Galenic system, the blood, the phlegm, the yellow bile, and the black bile. He likewise establishes three distinct kinds of spirits—the natural, the vital, and the animal; the first of which he supposes to be a subtile vapour arising from the blood; this, conveyed to the heart, becomes, when conjoined to the air taken into the lungs, the vital spirits, which are changed into the animal kind in the brain. These three species of spirits our author imagined to serve as instruments to distinct faculties: the natural faculty, which he supposed to reside in the liver, and to preside over the nutrition, growth, and generation of the animal body; the vital faculty, which he lodged in the heart, and imagined that through the intervention of the arteries it communicated warmth and preserved life; while the animal faculty, according to Galen, has its seat in the brain, is the cause of motion and sensation, and presides over all the other faculties. The origin or principle of motion in these respective faculties, Galen, as well as Hippocrates, calls *nature*.

The authority of Galen, notwithstanding the tissue of extravagances and idle conjectures of which his systems were formed, continued to prevail until the downfal of the Roman empire. The seat of learning now became the theatre of war, and the arts of peace took refuge in the Eastern nations. The Arabian succeeded to the Greek and Roman physicians, and still farther obscured the theories of medicine by the introduction of fresh absurdities. Anatomy was totally neglected, or at least not in any measure advanced, by the Saracens: they made some progress in the science of botany, and introduced several new drugs, principally of the aromatic kind, from the East, which retain still a place in the materia medica.

The mention of a singular controversy which occurred among the Arabian physicians, may serve to indicate the complexion of the times in relation to the dogmas and practice of physic.

Hippocrates had directed that in pleurisy blood should be drawn from the arm of that side which might be principally affected. Some of the Arabians contended that it should be taken from the side opposite; and such was the medical ignorance and fanaticism of the age, that a decree was issued from the university of Salamanca in Spain, forbidding any one to pursue the practice of Hippocrates. The members of this university even endeavoured to procure an edict from the emperor Charles V. to confirm their authority, alleging, that the practice they opposed was no less pernicious to medicine than Luther's heresy had been to religion!

From the time of the decay of learning to the commencement of the 16th century, the history of medicine furnishes no particulars of interest. This last is the period which gave birth to the celebrated Paracelsus. Now, all the facts and doctrines of medicine came to be explained by, and founded upon, imaginary principles of chemical philosophy. The ancient authors fell into disrepute; and the elements, qualities, and temperaments of the Greeks, were melted down and dissipated in the laboratory of the chemist. Fermentation, effervescence, ebullition, and deflagration with salts, sulphur, alkali, and mercury, came now to be familiarly, but without any precise signification, introduced among the terms of the medical art. With several, however, the Galenic philophy continued to prevail.

In the year 1628, Dr. W. Harvey, of London, first demonstrated and communicated to the world the most important fact of the circulation of the blood. This discovery afforded a new foundation for the whole structure of medical and physiological reasoning. Even this, like all other improvements in science, and bold innovations of established doctrines, met with very cold encouragement by the contemporaries of Harvey. It is said, that no physician or teacher of medicine, who had attained his 40th year, would subscribe to the fact; and that in thus conferring an incalculable benefit on the community, Harvey diminished his own contemporary reputation, and nearly lost his practice as a physician.

While some were industriously endeavouring to controvert the fact, others were busied in attempts to wrest the discovery from its author.

Servitus, a native of Spain, had, many years previous to the time of Harvey, published a Treatise on Medicine and Theology. In this work it is asserted, or rather perhaps conjectured, that the blood, by some unknown channel, passes from the pulmonary arteries into the veins. Even allowing that this intimation justly laid claim to the title of a discovery, it is merely a discovery of the passage of the blood through the lungs, and could in no measure interfere with the merit or be regarded as an anticipation of the Harveyian doctrine.

The period, however, had not yet arrived when a rational use was to be made of the important fact in question. As the alchemists had derided the Galenists, so the reasonings of the latter were now to give way to the mathematical sect of physicians, who by axioms, postulata, theorems, problems, experiments, and corollaries, ("a capite ad calcem armatos, et necem undique minitantes,") attempted to explain, in the most futile manner, the functions of life, and to regulate the remedial process.

The learned and industrious Boerhaave, of Leyden, whose name stands conspicuous in the annals of medicine, at length attempted to restore the authority of the ancient writings; and by uniting the doctrines of Hippocrates with the philosophy of the times, he framed a theory of medicine upon the supposition of acrimony, lentor, and other changes in the circulating fluids. From these changes he inferred the origin of all disease; and the process of cure is, according to Boerhaave, either the process of correcting or expelling acrimony from the body, or the correction of morbid viscidity or tenuity in

the humours. Boerhaave has, therefore, been considered the founder of the humoral pathology; a pathology which even to this day retains a material influence on the opinions, the phraseology, and the practice at least of the vulgar.

Contemporary with Boerhaave was the illustrious Hoffman, a German professor, and founder of a medical system. Dr. Staahl having first suggested, or rather borrowed from the ancients, the idea of the rational soul of man governing and directing the whole economy of his body, and obviating the adverse tendency of noxious agents by exciting such actions in the system as are calculated to effect their expulsion, or destroy their malignity; Hoffman endeavoured to demonstrate, that the first operation of the causes creating disease was the production of universal atony or spasm in the primary moving power of the system, and did not consist of changes produced either in the quantity or quality of the humours or fluids of the body, as taught by the celebrated Boerhaave.

The humoral, however, continued to prevail over the pathology of Haffman; and Dr. Cullen informs us, that "when he came to take a professor's chair in the university of Edinburgh, he found the Boerhaavian system then in its full force." In framing a system of his own, Dr. Cullen reverted to the theory of Hoffman; and indeed the whole of his pathology, as far as it relates to leading systematic doctrines, is scarcely any thing more than an attempt to unite the hypothesis of Hoffman with with the Stahlian principle of an intelligent, presiding, and preservative power.

We have thus rapidly conducted our readers over the ground of medical history, and have presented a faint outline of the prevailing systems of medical philosophy, from the time of the Grecian to the time of the "English Hippocrates;" to the period when the fanaticism and prejudice of system were shortly to give way before the precepts of genuine philosophy and temperate induction; when the medical science was to be established upon a new foundation; when chemistry was to undergo a reformation equally radical and important; when by consequence a new alliance was to be formed between these two sciences; when the language of metaphor and hypothesis was to be discarded from either; and when inquirers after truth were to be influenced and directed by the independant and invaluable maxim, "Nihil in intellectu quod non prius in sensu."

On nosology, or the classification of diseases. Dr. Sydenham was the first who proposed to adopt a division of diseases into class, order, and genus, upon similar principles with those of botanical arrangement. The idea has been followed out by several of Sydenham's successors, but by no means with that success which had been anticipated. The reason why nosologists have in some measure failed, is sufficiently obvious. While the objects of natural history possess a certain degree of uniformity, enabling the systematic to identify in a manner certain individuals, and thus to refer them to one class, scarcely any thing of this order is observed, or at least not sufficient to justify arrangement of the infinitely diversified phenomena of disease. For example: a certain series of symptoms shall present themselves during the life of an individual, which shall prove to have depended upon, or at least have been connected with, disordered condition of some particular organ. A careful register of such symptoms might be supposed to furnish the same guide to the pathologist and physician, as a recollection of the prominent character of a plant to the botanist or agriculturist. This, however, is by no means the case. Similar symptoms are not invariably characteristic of similar disorders. A cough may originate at one time from circumstances which would at another time suppress it. A catarrh of the nostrils will now be produced by a deficient, now by an excessive, action of precisely the same membrane. The generic terms then which are introduced into medicine, are extremely fallacious: they in fact convey no idea of the precise nature of that affection which they have been employed to indicate; and the difficulty is still greatly augmented when we recollect the endless diversities that must arise from the varied external circumstances, as affecting and modifying the constitutional character of the same individual.

A disease, then, as indicated by name, and described by signs, is in some measure an imaginary existence. Dr. Brown, the outline of whose doctrines is elsewhere exhibited (see the article Brunonian System), aware of the errors attached to nosology founded on symptoms, proposed to comprehend all morbid affections under the two leading divisions of diseases of increased and diminished excitement. Our author, however, in his opposition to particulars, went over to the other extreme of too indiscriminate and hasty generalization. The human frame is too complicated to admit of the simplification which Brown aimed at. His division is a guide to principle but not to practice.

A recent attempt has been made to include in one scheme both general principles and particular facts. This plan, however, notwithstanding the boldness of conception by which it was formed, and extraordinary ingenuity by which it has been executed, is defective. It rests upon a hypothetical, and therefore upon a sandy, foundation. Our readers who are acquainted at all with modern medicine, will be at no loss to conclude that we refer to the system of the late Dr. Darwin. By this author, excitability, which was left as an ultimate fact in the Brunonian theory, is attempted to be traced to its origin. The sensorial power, excitability, or spirit of animation, is conceived to be "a subtle fluid, residing in the brain and nerves, and liable to general or partial accumulation." The vital changes effected by the medium of this imaginary fluid, are, 1st, "Irritation, which is an exertion or change of some extreme part of the sensorium residing in the muscles or organs of sense, in consequence of the appulses of external bodies. 2. Sensation, an exertion or change of the central parts of the sensorium, or of the whole of it, beginning at some extreme parts of it, which reside in the muscles or organs of sense. 3. Volition is an exertion or change of the central parts of the sensorium, or of the whole of it, terminating in some extreme parts of it, which reside in the muscles or organs of sense. 4th. Association is an exertion or change of some extreme part of the sensorium, residing in the muscles or organs of sense, in consequence of some antecedent or attendant fibrous contractions."

With these assumptions as his guide, Dr. Darwin endeavours to penetrate deeper into the cause of disease

than is allowed by a mere knowledge of the condition of the fibre. The powers of the sensorium are the proximate cause; the fibrous action, the excitement of Dr. Brown, the proximate effect; and hence, from an ingenious, but by no means satisfactory, statement of the mode in which excitations are produced, he treats of diseases as occasioned by the comparative redundancy or deficiency of the sensorial power of irritation, sensation, volition, or association.

It would carry us far away beyond our limits to pursue this theory through the minutiæ of its ramifications. Some opportunities will be afforded in the course of the present article to acknowledge the obligations which medicine is under to its ingenious framer. We shall here confine ourselves to the statement of what we consider fundamental objections to the doctrines, and, by implication, the nosology or arrangement of Zoonomia.

In the first place, it does not distinguish between cause and effect, between fibrous motion and its source. Secondly, it substitutes, like the ancient systems, mere statements of phenomena for explication of their origin. Thirdly, and what is more immediately applicable to our present inquiry, it divides that which in its nature is indivisible.

Dr. Brown had defined excitement to be a certain state of fibrous action produced by the exciting powers acting upon the excitability. Dr. Darwin after him considers irritation or excitement as an exertion of the spirit of animation, exciting the fibres to contraction. Here we observe the want of precision alluded to, and the confusion originates from forsaking induction to embrace hypothesis. "On Dr. Darwin's principles the identical fibrous motion exists before the faculty of irritation can be exerted." The spirit of animation ought to have been stated as the unknown medium ("quo pacto adficiatur ignoratur") through which the excitement or irritation is produced.

Again, the sentient and fibrous changes which in the Darwinian system of life are thus connected, are not rendered more explicable by the intervention of a subtle fluid. The spirit of animation of Darwin, allowing its existence to be capable of proof, in no measure facilitates the conception of vital causation. As an exemplification of the last of the above objections, it may be urged, that when Dr. Darwin, in forming his classification, referred all morbid affection to the heads of irritation, sensation, volition, and association, he seems to have overlooked his former assumption, founded upon the inseparability and identity of the sensorial power or fluid. and not to have been aware he had already asserted that "propensity to action, whether it be called irritability, sensibility, voluntarity, or associability, is only another mode of expressing the quantity of sensorial power residing in the organ to be excited."

An increase then or diminution of one of these energies necessarily supposes an increase or diminution of all, "and the disorder of decreased irritability, ought also to be the disorder of decreased sensibility, voluntarity, and associability." The classification, then, is even in contradiction to the principles of Zoonomia. It is intricate and erroneous.

Perhaps the most consistent and comprehensive plan of arranging individual diseases would be that which, while it preserved the important fact in view, of the indivisibility of the living system, would take into its account the three leading, and in one sense separate, functions performed by the arterial, the nervous, and the glandular organization.

As approaching nearest to this plan, and likewise because it is in most general use in this country, at least as a text book for teachers of medicine, we shall make use in the present article of the nosology of Dr. Cullen, requesting the reader to recollect the unavoidable objections which oppose themselves to all systems and all classifications of morbid affections.

The following are the classes, orders, and genera of Cullen, with the exception of the class locales, which relates to those disorders principally that come under the head of surgery.

TABLE OF CLASSIFICATION.

Class I. Pyrexiæ. A frequent pulse, succeeding to shivering or horror; increased heat; disturbed functions; prostration of strength.

Order I. *Febris.* Pyrexia, independant of local affection as its cause; languor, lassitude, and other signs of debility.

Sect. 1. *Intermittentes.* Fevers arising from the miasma of marshy grounds, with an evident remission, the returning fits being almost always ushered in by horror or trembling. One paroxysm only in the day.

Genera. Tertiana; quartana; quotidiana.

Sect. 2. *Continuæ.* Fevers without intermission, not occasioned by marsh miasma, attended with exacerbations and remissions, though not very preceptible.

Genera. Synocha; typhus; synochus.

Order II. *Phlegmasiæ.* Fever, accompanied by local inflammation or topical pain, lesion, or disturbance of the internal functions; sizy blood.

Genera. Phlogasis ophthalmia; phrenitis; cynanche; pneumonia carditis; peritonitis; gastritis; enteritis; hepatitis; splenitis; nephritis; cystitis; hysteritis; rheumatismus; odontalgia podagra; arthropuosia.

Order III. *Exanthemata.* Contagious diseases, which only affect once during life, commencing with fever, and succeeded by phlogosis or inflammatory cruptions on the skin.

Genera. Erysipelas; pestis; variola; varicella; rubeola miliaria; scarlatina; urticaria; pemphygus; apthæ.

Order IV. *Hemorrhagiæ.* Pyrexia; spontaneous discharge of blood; blood when drawn from a vein of a sizy appearance.

Genera. Epistasis; hemaptisis; hæmarrhois menarrhagia.

Order V. *Profluviæ.* Pyrexia; inordinate discharge, but not of blood.

Genera. Catarrh; dysenteria.

Class II. Neuroses. A lesion of sense and motion, without idiopathic pyrexia or local disorder.

Order I. *Comata.* A diminution of voluntary motion with sleep, or a deprivation of sense.

Genera. Apoplexia; paralysis.

Order II. *Adynamiæ.* Diminished voluntary motion, whether vital or natural.

Genera. Syncope; dyspepsia; hypochondriasis; chlorosis.

Order III. *Spasmi.* Irregular action of the muscular fibre.

Sect. 1. In the animal functions.

Genera. Tetanus; trismus; chorea; raphania; epilepsia.

Sect. 2. In the vital functions.

Genera. Palpitatio; asthma; dyspnæ; pertussis.

Sect. 3. In the natural functions.

Genera. Pyrosis; colica; cholera; diarrhœa; diabetes; hysteria; hydrophobia.

Order VI. *Vesaniæ.* Derangement of judgment, independantly of pyrexia or coma.

Genera. Amextia; melancholia; mania; oncirodynia.

Class III. Cachexiæ. A depraved habit of body, without idiopathic pyrexia orneurosis.

Order I. *Macores.* A wasting of the whole body.

Genera. Tabes; atrophia.

Order II. *Intumescentiæ.* A swelling of the whole or of the greatest part of the body.

Sect. 1. *Adiposiæ.* Fatty swellings.

Genus. Polysarcia.

Sect. 2. *Flatulosæ.* Windy swellings.

Genera. Pneumatosis; tympanites; physometra.

Sect. 3. *Hudropes.* Watery swellings.

Anasarca; hydrocephalus; hydrorachitis; hydrothorax; ascites; hydrometra; hydrocele; physconia.

Order III. *Impetigines.* Cachexies, chiefly deforming the skin and external parts of the body.

Genera. Scrophula; syphilis; scorbutus; elephantiasis; lepra; frainbæsia; trichoma; icterus.

Class I. Order I.—*Febris.*

What is fever? To this question it appears difficult to give a precise and satisfactory reply. It is observed by the author of Zoonomia, that "the term *fever* is given to a collection of morbid symptoms, which are indeed so many distinct diseases that sometimes appear together, and sometimes separate; hence it has no determinate meaning, except it signifies simply a quick pulse, which continues for some hours;" in which sense Dr. Darwin employs the word throughout his ingenious work.

On this head, however, we differ in opinion with the author just mentioned. An increased action of the sanguiferous system shall be induced sometimes by, and at other times independant of, a diseased irritation, without being accompanied with other peculiar feelings, which, not restricting ourselves to the etymological signification of the term *fever*, we purpose regarding as necessary constituents of this, as a distinct malady.

In every proper fever, there is a feeling of depressed power, which essentially differs from actual debility. "A diminution of strength in the animal functions," which constitutes part of Dr. Cullen's definition of the febrile state, is scarcely characteristic of the condition to which we allude. It is a feeling with which every one is more or less familiar, and appears to indicate rather obstructed than exhausted strength. Dr. Rush endeavours to illustrate this necessary constituent of genuine fever as a distinct expression from simple irritation of the blood-vessels on the one hand, and mere debility on the other, by comparing it with the smothered sound which may be supposed to be emitted from a musical instrument, provided a heavy weight were applied to the chords; which ought to be suffered to vibrate freely and without obstruction, in order to produce a full and harmonious sound. An illustration of a similar nature is likewise employed by Dr. Jackson.

Dr. Brown defines fever, "an asthenic disease that disturbs the pulse." In this, however, there is the same want of distinction which we have just complained of in the definition of Dr. Cullen. Asthenic diseases are diseases of deficient excitement; but in fevers we have an interruption rather than diminution of power. The faculties are locked up, not lost.

Of the phenomena of fever. Dr. Cullen very properly selects the more ordinary circumstances that present themselves in the course of an attack of intermittent fever, as an example of what occurs with more or less regularity in every case of genuine febrile disorder.

"The following," he says, "are to be observed in such a paroxysm. The person is affected with languor or sense of debility, a sluggishness in motion, and some uneasiness in exerting it, with frequent yawning and stretching. At the same time the face and extremities become pale, the features shrink, the bulk of every external part is diminished, and the skin over the whole body appears constricted as if cold had been applied to it. At the coming on of these symptoms, some coldness of the extremities, though little taken notice of by the patient, may be perceived by another person. At length the patient himself feels a sensation of cold, commonly first in his back, but then passing over his whole body; and now his skin feels warm to another person. The patient's sense of cold increasing, produces a tremor in all his limbs, with frequent successions or rigors in the trunk of the body. When this sense of cold and its effects have continued for some time, they become less violent, and are alternated with warm flushings. By degrees the cold goes off entirely; and a heat greater than natural prevails and continues over the whole body. With this heat the colour of the skin returns, and a preternatural redness appears especially in the face. Whilst the heat and redness come on, the skin is relaxed and smooth, but for some time continues dry. The features of the face and other parts of the body, recover their usual size, and become even more turgid. When the heat, redness, and turgescence, have increased and continued for some time, a moisture appears on the forehead, and by degrees becomes a sweat, which gradually extends downwards over the whole body. As this sweet continues to flow, the heat of the body abates; the sweat, after continuing for some time, gradually ceases, the body returns to its usual temperature, and most of the functions are restored to their ordinary state.

Species of fevers. The general division of systematics is into continued and intermittent. The very correct description above given answers, as we have stated, to a single paroxysm or fit of fever. It is not however often that the disorder terminates with the decline of the paroxysm. In the course of a certain time it is renewed; and according to the suddenness or tardiness of the paroxysm's recurrence, the fever is called continued, remittent, or intermittent. Sometimes, indeed, the disordered actions recur with such celerity, that the fever appears to be one continuous series; "the remission is inconsiderable, is perhaps without sweat, and the returning parox-

ysm is not marked by the usual symptoms of a cold stage, but chiefly by the exacerbation or aggravation of the hot one." The disease in this last case is considered as a continued fever; in which, however, there is, though not the distinct stages of an intermittent, almost invariably, especially in the earlier periods, a diurnal remission and recurrence of paroxysm. Of intermittent fevers, the paroxysms, such as we have just described, are always finished in less than 24 hours, and most frequently are not extended to nearly this time.

We are then furnished with a natural division of fever into intermittent and continued, which however have many circumstances in common, and often pass into each other; thus, what is termed in the schools a quartan intermittent, formed by an interval of 72 hours from the commencement of one to the commencement of another paroxysm, will in its course become a tertian ague, with only 48 hours of interval: this again shall fall into a quotidian, characterized by an interval of only 24 hours. A quotidian shall pass into the state of a remittent, and this last be converted into a true continued fever.

Besides, however, this leading distinction of fever, from the times of the recurrence of the fits, we have many others arising from the nature of the constitution of the individuals attacked, the prevailing condition of the atmosphere, and other extraneous circumstances, and likewise (what is ascertained however with less exactness) the specific difference of the exciting cause; thus, common fever has sometimes the inflammatory, at others the typhoid, character. Thus are presented the bilious remittent fever of damp and warm climates, the yellow fever of the West India islands, the jail fever of crowded prisons, and the plague in Eastern countries.

On Cullen's genera. It will be perceived that under the appellation of fever we confine ourselves to the consideration of what has been by way of distinction termed simple fever, and perhaps with propriety regarded by Mr. Wilson as "the only general disease," other diseases being either local, or general and local. Thus the sensitive irritated fever of Darwin, which forms principally the phlegmassia of Cullen, is a disorder either symptomatic of, or at least supported by, local irritation.

The genera of Dr. Cullen of continued fever, are,

1. *Synocha.* "Great heat, pulse frequent, strong, and hard; high-coloured urine, the functions of the sensorium not much impaired." Such character. however, does not answer to any case of simple fever; it is the definition of what Dr. Brown calls the sthenic, which is opposed to the true febrile state.

2. *Typhus.* "A contagious disease, the heat not much increased, pulse frequent, small, and weak; urine little changed, sense much impaired, and the strength greatly diminished." This definition approaches nearest to the more usual form of fever in this country. That part of the definition, however, is extremely defective which describes the heat as not much increased.

3. *Synochus.* This is made by Cullen a kind of intermediate disease between synocha and typhus.

Exciting causes of fever. On this subject the most opposite opinions prevail. It is imagined by some, that no case of genuine fever, beyond those ephemeral-irritations which are of daily occurrence, can possibly originate with the previous application, either through the medium of the lungs, or the surface of the body, of a certain something generated in the system of another individual in the course of the same disease. Others infer, from the daily observation of febrile diseases where no communication with the sick can be traced or suspected, that although the febrifacient matter just spoken of be in many, it is not in all instances the cause of fever; that cold, damp, heat, putrid exhalations whether animal or vegetable, insufficient ventilation, the depressing passions, &c. are all, either singly or in conjunction, capable, under some circumstances, not merely of predisposing to, but of actually engendering, proper fever. Lastly, there are some who consider contagion, or the generation in fever of specific febrifacient matter, as totally imaginary; and conceive in instances where fever has spread by communication, that either certain undetected conditions in the air, or the confined effluvia of animal excretions accumulated by want of cleanliness and ventilation, with other circumstances, are causes sufficiently adequate to produce the affection, without supposing the agency of a specific and occult power. "It is from nastiness," says one of the most celebrated of the anticontagionists, "degenerating into infection by chemical changes, that the bodies, clothes, beds, and apartments, of the poor in Great Britain, derive their poisonous, their pestilential charge. By a common putrefactive process, this *septic venom* is formed, and derives none of its qualities from pulsating arteries or glands. Away then with this preposterous phrase, 'from the poison engendered by septic processes.' Let human contagion for the future mean nothing but small-pox, vaccinia, and the kindred forms of morbid secretions." (Dr. Rush.)

Notwithstanding, however, the circumstances here pointed out and rested upon, we conceive the general facts to be in favour of poison engendered, independant of mere putrefaction or filth; and we shall shortly state the grounds upon which our opinion is established, when upon the subject of preventing the spread of fever. That contagion, however, is absolutely requisite to the production of this disorder, in every instance, does not seem an opinion authorized by facts, although it must be admitted that the negative is incapable of proof: for when we refer to its generation from mere filth and sloth, under the circumstances just mentioned from Dr. Rush, it may be replied, that contagion in such cases might have been in some manner conveyed without suspicion, and that the situation of the recipient constituted merely a predisposition to suffer from its application.

A contest has likewise arisen respecting the production of intermittent as well as continued fever. Intermittent fevers are observed to prevail especially in situations the soil of which is marshy: on this account it has been imagined, that they are invariably consequent upon a certain taint or miasma arising from moist ground. "The similarity of the climate, season, soil, in the different countries in which intermittents arise, and the similarity of the disease, though arising in different regions, concur in proving that there is one common cause of these diseases, and that this is the marsh miasma." (Cullen.) Dr. Brown and others have contended, that the noxious influence of cold or of heat, "when the common asthenic noxious powers accompany either," are sufficient to occasion genuine intermittent. It however

appears an established principle, that intermittent fevers are most frequently the offspring of poison arising from marshes or moist ground. That other causes act in conjunction, and augment the predisposition, is likewise an established fact; for the agues of marshy countries occur most abundantly at cold seasons which have succeeded hot ones, and especially amongst those whose diet has been innutritious and unstimulating. It is also beyond dispute that more cold or poor living will induce ague after the habit has been once established.

Proximate cause of fever. On this subject the following errors appear to have misled systematics. 1. A want of distinction between final and proximate cause; between inquiries instituted in order to divine the intentions of nature, and a careful examination of the phenomena of nature as they occur in sequence. 2. The indivisibility of the body, and the universal nature of the disorder, have been too much overlooked. Fever has been considered as an affection of parts rather than of the universal system. 3. An error which appears to result from the conjunction of the two former; that shrinking and coldness of the external surface, which is merely a consequence and concomitant effect resulting from a febrile attack, has been viewed as a cause of the other symptoms which present themselves in the course of the affection.

"The remote causes of fever," says Dr. Cullen, "are certain sedative powers applied to the nervous system, which diminishing the energy of the brain, thereby produce a debility in the whole of the fuctions, and particularly in the action of the extreme vessels; this debility proves an indirect stimulus to the sanguiferous system, whence by the intervention of the cold stage, and spasm connected with it, the action of the heart and larger arteries is increased, and continues till it has had the effect of restoring the energy of the brain, of extending this energy to the extreme vessels, of restoring therefore their action, and thereby especially overcoming the spasm affecting them."

In the historical sketch of the progress of medical theory with which we introduced the present article, it was observed that the spasmodic theory of Hoffman engendered that of Dr. Cullen. In the hands, however, of this last systematist, the doctrine in question appears to have received mutilation rather than amendment: Dr. Cullen added another set of entangled links to the previously entangled chain. The shrinking, coldness, and general inactivity, observed at the commencement of fever fits, and which are the necessary consequences of the sudden quiescence throughout the system, induced by the peculiar action of the noxious powers producing fever, our author considers as one of nature's first steps in obtaining relief and obviating the progress of the disorder.

On this theory we may in the first place remark, that when the progress of a febrile affection is arrested by remedies applied during the first or cold stage, both the torpor of the brain and the shrinking of the surface may be removed without the intervention of the hot fit. Indeed, obviating the recurrence of this constitutes the cure of fever. The succession, then, of the hot fit is not a necessary consequence of the previous cold one, much less is it an agency contrived by nature to remedy this last. The theory is likewise "erroneous, in as far as it enters into the supposed intentions of nature."

Secondly, the action of the heart and larger arteries is not, as is justly observed by Dr. Darwin, occasioned in the mechanical manner of reaction, which the theory we are canvassing supposes. During the continuance of the cold fit, the whole circulation is lessened, or in a manner suspended, the blood is not retreating for safety to the centre, less blood passes through the lungs as well as through the vessels on the surface of the body; the fortress, and not merely the outposts, has received the attack of the enemy. Now, when the hot fit comes on, the marks of irritation, or as Dr. Brown happily terms it, of "counterfeited vigour," by which it is characterized, are merely consequent upon the natural stimuli acting upon accumulated irritability, of irritability accumulated by the previous quiescence of the cold stage, and are not to be attributed to the blood's reacting and flowing back in order to influence and occupy the parts and cavities which it had deserted. This supposed action and reaction cannot indeed take place in that mode and to that extent which our theorists imagine. The human body is a living and not an hydraulic machine. The blood is not dammed up at one part in order to rush with violence into another. To illustrate: When even a part of the body only, as the hand, is immersed in water, or in any other way abruptly exposed to a diminished temperature for a short period, a lessened fibrous or vital action is the immediate consequence, the sensorial power or excitability accumulates in a corresponding ratio, and when the part is now again subjected to the influence of those powers which were previously operating, an irritative and disturbed, in place of regular and healthy, action succeeds; the blood, however, does not flow into the empty vessels like the waters of a river into lateral channels: not more than the same volume of blood, in cases of much weakness not so much, now circulates through parts, the excitability of which has been changed, and an accelerated, but not, properly speaking, increased motion, with febrile heat, is the consequence.

We have perhaps conceded too much to the spasmodic theory of fever, in likening the state of the surface in the cold fit to that produced in consequence of diminished temperature, for in this last the shrinking is directly produced; whereas, in fever, it is occasioned indirectly, or, as we have previously noticed, is merely one of the effects arising from the general interruption of the functions. Fever does not commence by attacking exclusively "the extreme vessels and the capillaries of the surface."

The spasmodic theory of fever then, is not only a substitution of terms for an explanation of facts, but even the phraseology which it employs in order to trace and connect the leading symptoms of the malady, appears to be deduced from defective knowledge of the laws and qualities of life. It is physically, metaphysically, and practically wrong. "Fever fits are not efforts of nature to relieve herself." Darwin.

Before proceeding farther, it may be proper to notice one or two defects, as they appear to us, in the ingenious theory of the author of Zoonomia. In our remarks on nosology, the mistakes which Dr. Darwin had been led into from his untenable division of sensorial power, were

hinted at. These mistakes appear to us to be evident in the learned author's attempts to form a sympathetic theory of the disorders under notice: a theory, which, in our opinion, involves the second error which we have above stated, viz. that of overlooking the indivisibility of the body, or the universal distribution of sensorial power, and regarding fever rather as an affection of parts than of the whole frame. It likewise, by consequence, embraces the erroneous doctrine of ascribing the secondary actions in fevers to the cutaneous torpor. The cold fit of simple fever, says Dr. Darwin, consists of a torpor of the cutaneous capillaries, with their mucous and perspirative glands, which is extended by direct sympathy to the heart and arteries. The torpor, however, of the heart and arteries is coexistent with, and not consequent upon, the inaction of the cutaneous vessels: the sensorial power residing in the former at the time of an attack of fever, must be affected in the same manner as the sensorial power of the latter; and the admission of association, is the introduction of an unnecessary link in the chain of cause. That distant parts sympathize with each other, in a manner which phisiology has not hitherto been able to unfold, as the stomach with the surface of the body for example, is admitted; in the case of fever, however, we wish particularly to insist upon such sympathy as an explanation of symptoms being superfluous: the heart and arteries, the stomach, the surface of the body, the secretory glands, all receive a diminution or sudden interruption of their functions at the same moment of time, and from the same cause: they are simultaneous and not successive effects. Dr. Darwin seems equally unfortunate in referring the hot skin and remaining quiescence of some internal organs, as of the stomach, in the second stage of fever, to reverse sympathy. Sympathy cannot be direct in one instance, and reverse in another: "The laws of association are invariable, or they do not exist."

What then is the cause of fever? It is an abrupt suspension and consequent disruption of all the connected movements of the animal frame by which the balance of excitement is overthrown, "the laws of excitability are changed, and in consequence of which the same agents no longer produce the same effects. Fever differs from debility inasmuch as the latter is a gradual and regular exhaustation, not an abrupt interruption of the powers of life; it differs from strength, as strength consists in a powerful and equable excitement, while fever, however it may "counterfeit vigour," is never attended by the necessary constituent of vigour, regular and orderly display of power.

The primary cold, or as the Latins term it, "horror," is from the quiescence that has been induced; during this state of quiescence, a new and inordinate condition of the excitability is established, and by consequence both the external and internal stimuli excite perturbed in the place of orderly and usual actions: action without power commences; hence morbid heat is generated, diseased associations are formed, and without being in a state of actual weakness, the whole system sinks, oppressed. The plain indications of

Treatment in fever, are therefore to break the morbid associations on which this oppression is established, or obviate the symptoms by which it is continued; to diminish the cold in the cold stage, the heat in the hot stage, and not to await the sanative process of nature, either of dissolving spasm, or of correcting and expelling morbific matter. The various remedies employed for these purposes are, the external and internal use of cold and warm water; refrigerants, sudorifics, opiates, emetics, purgatives: on each of these, we shall introduce a few separate remarks; in the course of which an opportunity will be afforded, of inquiring more minutely into the pathology of the febrile state.

Of cold and tepid affusion, and ablution.—Cold water internally.—Cold air.—The medical reports of Dr. Currie, on the effects of water, cold and warm, in the treatment of fever, are introduced in the following manner:

Narrative of Dr. Wright.

"In the London Medical Journal for the year 1786 Dr. William Wright, formerly of the island of Jamaica, gave an account of the successful treatment of some cases of fever, by the ablution of the patient with cold water.

"On the 1st of August, 1777," says Dr. Wright, "I embarked in a ship bound to Liverpool, and sailed the same evening from Montego-bay. The master told me he had several sailors on the same day we took our departure, one of whom had been at sick quarters on shore, and was now but in a convalescent state. On the 23d of August, we were in the latitude of Bermudas, and had had a very heavy gale of wind for three days, when the above-mentioned man relapsed, and had a fever with symptoms of the greatest malignity. I attended this person often, but could not prevail on him to be removed from a dark and confined situation to a more airy and convenient part of the ship; and as he refused medicine and even food, he died on the eighth day of his illness.

"By my attention to the sick man, I caught the contagion, and began to be indisposed on the 5th of September; and the following is a narrative of my case, extracted from notes daily marked down: I had been many years in Jamaica, but except being somewhat relaxed by the climate and fatigue of business, I ailed nothing when I embarked. This circumstance, however, might perhaps dispose me more readily to receive the infection.

"Sept. 5th, 6th, 7th: Small rigours now and then; a preternatural heat of the skin; a dull pain in the forehead; the pulse small and quick: a loss of appetite, bu no sickness at the stomach; the tongue white and slimy; little or no thirst; the belly regular; the urine pale and rather scanty; in the night restless with starting and delirium.

"Sept. 8th. Every symptom aggravated; with pains in the loins and lower limbs, and stiffness in the thighs and hams.

"I took a gentle vomit on the second day of this illness, and next morning a decoction of tamarinds; at bedtime an opiate joined with antimonial wine; but this did not procure sleep or open the pores of the skin. No inflammatory symptoms being present, a drachm of Peruvian bark was taken every hour for six hours successively, and now and then a glass of port-wine, but with no apparent benefit. When upon deck my pains were greatly mitigated, and the colder the air the better. This circumstance, and the failure of every means I had tried,

encouraged me to put in practice on myself, what I had often wished to try on others, in fevers similar to my own.

"Sept. 9th. Having given the necessary directions, about three o'clock in the afternoon I slipt off all my clothes, and threw a sea-cloak loosely about me till I got upon deck, when the cloak also was laid aside: three buckets of salt water were then thrown at once upon me; the shock was great, but I felt immediate relief. The head-ache and other pains instantly abated, and a fine glow and diaphoresis succeeded; towards evening, however, the same febrile symptoms threatened a return, and I had again recourse to the same method as before, with the same good effect. I now took food with an appetite, and for the first time had a sound night's rest.

"Sept. 10. No fever, but a little uneasiness on the hams and thighs; used the cold bath twice.

"Sept. 11. Every symptom vanished; but to prevent a relapse I used the cold bath twice. Mr. Thomas Kirk, a young gentleman, passenger in the same ship, fell sick of a fever on the 9th day of August; his symptoms were nearly similar to mine, and baving taken some medicines without experiencing relief, he was desirous of trying the cold bath; with my approbation he did on the 11th and 12th of September, and by this method was happily restored to health. He lives at this time (Jan. 1786) near Liverpool."

We have thus presented our readers with this important narration of Dr. Wright, both as it furnishes a history of fever, as it details the mode in which the cold affusions should be employed, and as it was confessedly the means of introducing this most valuable remedy into general practice. We shall now add from Dr. Currie the more particular rules which ought to govern the use of the affusion or aspersion of cold water in fevers, and then make one or two observations on the nature of its operations.

"The safest and most advantageous time," says Dr. Currie, "for using the cold water is, when the exacerbation is at its height, or immediately after its declination has begun; and this has led me almost always to direct it to be employed from six to nine in the evening; but it may be safely used at any time of the day, *when there is no sense of chilliness present, when the heat of the surface is steadily above what is natural, and when there is no general or profuse perspiration.*—These particulars are of the utmost importance: for, 1st. If the affusion be used during the cold stage, the respiration is nearly suspended; the pulse becomes fluttering, feeble, and of incalculable frequency; the surface and the extremities become doubly cold and shrivelled, and the patient seems to struggle with the pangs of instant dissolution. I have no doubt, from what I have observed, that in such circumstances the repeated affusions of a few buckets of cold water would extinguish life. This remedy should therefore never be used when any considerable sense of chilliness is present, even though the thermometer applied to the trunk of the body, should indicate a degree of heat greater than usual.

"2nd. Neither ought it to be used, when the heat measured by the thermometer is less than, or even only equal to, the natural heat, though the patient should feel no degree of chilliness. This is sometimes the case towards the last stages of fever, when the powers of life are two weak to sustain so powerful a stimulus.

"3d. It is also necessary to abstain from the use of this remedy under profuse sensible perspiration, and this caution is more important in proportion to the continuance of this perspiration."

"Under these restrictions," our author adds, "the cold affusion may be used at any period of fever; but its effects are more salutary in proportion as it is used early. When employed in the advanced stages of fever, where the heat is reduced and the debility great, some cordial should be given immediately after, and the best is warm wine."

Observations. Cold water as a remedy for fever, may be conceived to operate upon a twofold principle. In the earlier stages, and before the vital power is too much harassed and oppressed to endure a violent shock, the copious and sudden affusion of cold water all over the naked body, appears to effect its beneficial purposes in part by the abruptness of its agency; it in a manner severs the chain of diseased associations, and restores the healthy and orderly movements of the frame. This operation is not, as has been suggested, mechanical: it is in some measure similar to that produced by the operation of an emetic, to which it is in every respect greatly preferable, or to sudden mental agitation. In the language of the schools, it cuts short fever.

When, however, the diseased associations are more firmly established, and the vital power greatly oppressed by the disorder's continuance, although the surface of the body retains its morbid heat, the water is to be applied, not in the way of sudden affusion, but by washing with a spunge, and this under the restrictions enjoined by Dr. Currie, or we may safely say, while it is found genial to the patient's feelings, ought to be resorted to in every case of simple fever. The action of the water at this time is somewhat different fron that in the previous period, or under different circumstances of the disorder. It proves a direct stimulus. But how, it has been urged, can the negative of a power prove stimulative? "Darkness might as well be called a stimulus to the eye, or hunger a stimulus to the stomach, as cold to our sense which perceives heat." Darwin. To this it has been replied by Dr. Currie, and before him by Dr. Beddoes, that the objection is founded upon a disregard of the sentient principle: "Cold," says the latter author, "may very often be so applied as, by removing the very disagreeable sense of heat, that attends some diseases, to produce an effect equivalent to stimulation. It is, I believe, exactly in this way, that bathing the body with cold water proves serviceable in low fevers."

From the urgency, however, of the debility, or from the prejudices of the patient or his friends, in some periods of fever, even the application of cold water in the way of ablution may be regarded as too severe. In this case tepid ablution has been made to supply its place, and often with propriety and success; it is, however, particularly deserving of remark, that unless this last be used with precaution, the object of the practitioner in its choice is defeated, as the evaporation from the surface is more copious from the tepid affusion; and this is one of the most powerful, indeed, strictly speaking, the only means of abstracting heat. The term tepid is applied by Dr.

Currie to water, from 87° to 97° of Fahrenheit; from 87° to 75° the water is dominated cool. Cold water may be given internally, and with the utmost freedom, in the hot stage of the febrile paroxysm. Its use, however, requires to be carefully regulated by the same restrictions as in the external application; it must never be given unless the heat of the surface be steadily above the natural standard. Draughts of cold water have been known, when properly administered, to procure a sudden solution of the disease.

Cold air. The extraordinary melioration in the modern practice of medicine, as it relates to the treatment of fever and febrile diseases, is not confined to the copious use of affusion and ablution. The terrors of our predecessors, in relation likewise to cold air, are fast departing; and the importance of its free admission in the apartments of the febrile sufferer especially, comes to be generally acknowledged and applied. It has been stated by a physician, above all praise for fidelity of observation and justness of remark, that the corrupted air of sick rooms, from neglect of ventilation, has been much more fatal even among the higher classes of society, than the virulence of the disease itself: "Vereor ne quidam ægroti non tam morbo suo perierint, quam halitibus putribus, quos discuti vetuit præpostera amicorum cura." Heberden.

The utility of cold air in fever is referrible to two principles: 1st. That of immediately lowering the heat of the surface, and thus taking off the oppression occasioned by such heat: and 2ndly, from affording a larger quantity of oxygen at each inspiration. The first of these principles is sufficiently evident, and does not require any further illustration: if cold ablution prove beneficial chiefly by virtue of diminishing the temperature of the body, it necessarily follows that coldness in the circumambient atmosphere must be attended with precisely similar effects: but on the purity, as connected with diminished temperature of the atmosphere, it may not be improper to embrace the present opportunity of offering one or two remarks. A given bulk of air at an inferior temperature, contains more of the oxygenous principle than the same quantity at a superior degree of heat; hence the greater refreshment which is experienced from the inhalation of a cold and dense, over that of a warm and rarefied atmosphere; hence, in part, the more vigorous digestion and keen appetite of a healthy individual during the winter, than the summer months; and finally, by the relief a febrile patient experiences from the inspiration of such air, it is rendered evident, both that the heat of fever originates, and is kept up, independently of those organs which modern chemistry and physiology have supposed to be the sole organs for the supply of heat to the living system. From this fact Dr. Reid infers, and we think with justice, that the constant equality of animal temperature in a condition of health, has more dependance upon living actions in general than upon the chemical evolution of caloric in the lungs, according to the ingenious theory first suggested by Dr. Crawford, but since materially modified. See Physiology.

But the frigorific virtue of a more oxygenous atmosphere, when received into the lungs of a febrile invalid, is a further proof, that however violent the reaction, as it has been erroneously called, such reaction is, in every case of genuine fever, far from being an evidence of actual increase of power. Whatever theory we adopt respecting the precise mode in which pure air influences the animal economy, an uniformity of opinion must prevail, that it is, in the strictest sense of the word, an exciting agent. Now as far as it operates beneficially in fever, it reduces the inordinate heat; that power then which actually and properly exists, by this very agency moderates the turbulent action, and by consequence reduces the prevailing morbid heat. The admission of cold air requires likewise to be restricted to the hot stage, and to be limited by the patient's feelings; a current of cold air passing rapidly over the body while in a state of perspiration, may be productive of fatal consequences.

Of refrigerants in fever. Besides, however, the employment of cold water, and the free admission of a cool and pure atmosphere, other agents have been had recourse to, and with considerable effect, in order to abate the inordinate heat of fever. From possessing the faculty of cooling the system, certain medicines have been distinguished by the term refrigerants: refrigerants are principally chosen from the vegetable acids, and the different neutral salts; and so evident is their power in reducing animal temperature, that they have properly been made to constitute a considerable part of regimen in fever. Indeed nitre, and other neutral salts, with the vegetable acids, have been received into some systems of classification, under the distinct head of febrifuge medicines. The modus operandi of refrigerants has not perhaps hitherto received explanation; the substances of which they are composed are for the most part those which contain oxygen in a concentrated, and, at the same time, loose state of combination; from this circumstance, their action has been ingeniously but not perhaps satisfactorily accounted for. "It has been sufficiently established," says a modern writer, "that the consumption of oxygen in the lungs is materially influenced by the nature of the ingesta received into the stomach; that it is increased by animal food and spirituous liquors, and, in general, by whatever substances contain a comparatively small quantity of oxygen in their composition. But the superior temperature of animals is derived from the consumption of oxygen gas by respiration; an increase of that consumption must necessarily, therefore, occasion a greater evolution of caloric in the system, and of course an increase of temperature, while a diminution in the consumption of oxygen must have an opposite effect. If, therefore, when the temperature of the body is morbidly increased, substances be introduced into the stomach, containing a large proportion of oxygen, especially in a state of loose combination, and capable of being assimilated by the digestive powers, the nutritious matter received into the blood must contain a larger proportion of oxygen than usual; less of that principle will be consumed in the lungs, by which means less caloric being evolved, the temperature of the body must be reduced; and this operating as a reduction of stimulus, will diminish the number and force of the contractions of the heart." Murray's Materia Medica.

This reasoning is perhaps more specious than just. In the first place, the remarks which we have above introduced on the actual diminution of febrile heat from in-

haling an oxygenous atmosphere, seem to oppose the theory of refrigeration, from "less of the oxygenous principle being consumed in the lungs." Secondly, it may be noticed that the effects of these medicines are too speedy and direct to admit of the supposition of this intermediate kind of agency; and thirdly, although the refrigerantia are for the most part, they are not universally, substances which contain this superabundance of the oxygenous principle. The saline draught, for example, appears to moderate febrile heat, principally by reason of the carbonic acid gas that it contains.

Chemical reasoning has recently been extensively applied to the developement of the mode in general in which the functions of the stomach and lungs are connected, and as this inquiry is closely related both to the theory of febrile heat, and the dietetical as well as the medicinal management of the febrile invalid, it may not be improper to detain the reader by one or two further reflections on this very interesting point of discussion. It is an axiom of Hippocrates, that animal food should not be given in fever; an axiom which was no doubt founded upon observation of its general irritating and disordering tendency. Modern physiology, however, has not rested content with a knowledge of the fact, but has endeavoured to divine its immediate cause. That digestion of the food is, cæteris paribus, in proportion to the oxygenation of the blood; or to avoid an expression involving theory, to the purity of air and freedom of inspiration, which an individual enjoys, is without question; and it is further evident from daily observation, that the facility of assimilating animal food, in particular, is increased by air, exercise, and whatever promotes an uninterrupted circulation through the pulmonary organs. Hence it is said, we are furnished with an explanation why animal diet is uncongenial to the patient in fever. The pulmonary circulation is impeded by febrile oppression, less oxygen is received from the atmosphere, and the power of assimilating materials which contain the hydrogenous and azotic principles in abundance is consequently weakened, or, as we have heard it expressed still more chemically, less fuel or combustible matter is required, on account of there being less power of consuming such fuel, or of maintaining combustion.

Perhaps the peculiarity or distinct nature of living action, has not been sufficiently attended to by modern physiologists of the chemical school. That hypothesis, the outline of which we have just delineated, appears at first sight perspicuous and unobjectionable, but when pursued more in detail, facts present themselves which are in some measure at variance with its fundamental principles.
